Mass exhumation may also take place as a result of the pressures to develop historic burial grounds in urban areas such as London, England. Recent exhumation projects include the King's Cross Eurostar platform that extended the train terminus directly into the cemetery of Old St. Pancras Church. Clearance at this site had taken place historically, and in the late 19th century the writer Thomas Hardy, while an architecture student, was responsible for supervising the exhumation of the cemetery for the insertion of the underground tunnel and structural support for the overland railway line. This experience had a profound effect on Hardy, and it was during this time he wrote the poem "Neutral Tones," reflecting his persistent problem relating to women. Hardy's later poems "The Levelled Churchyard" and "Ah, Are You Digging on My Grave" seem to be directly influenced by his experience at St. Pancras. Today this type of work may be conducted within crypts or cemeteries; it is occasionally carried out by undertakers but most commonly by specialist exhumation companies, archaeologists, or both. However, the experience of being involved in mass exhumation is difficult, and many modern archaeologists working in recent or historic burial grounds complain of bad dreams or poor sleep.

Excavation

When conducted on ancient or medieval cemeteries by professional archaeologists, exhumation is referred to as excavation. This scientific process is designed to get the most cultural data on an ancient society as possible and will include the three-dimensional recording of individuals' bodies, the context within which they were situated, and the identification and preservation of grave-goods. Trained physical anthropologists are often used to ascertain the age at death, sex, health, and diet of the individuals from their skeletal remains. This practice is, like exhumation, often conducted in preparation for commercial development and occasionally by university teams for research.

However, there are social and cultural taboos surrounding the exhumation or excavation of the dead, and in many societies it is viewed very negatively. Indeed, in New World countries, particularly in North America and Australia, the different views of archaeologists, construction companies, and indigenous groups have resulted in conflict that is often based on different attitudes to the past and

views as to what is of most cultural value: excavation or preservation. This conflict seems to be influenced by the nature of the postcolonial relationship between indigenous and nonindigenous populations. In the United States, for example, the arguments surrounding access to ancient cemeteries and the repatriation of the dead center on the differential treatment of Native American and colonial Caucasian remains. Many agree that the debate has political undercurrents and has provided an opportunity for the Native American population to regain control over their cultural heritage.

In Old World countries, the debate is often related to religion or religious organizations: The Jewish community objects to the disturbance of the dead, whereas for Protestant, Catholic, and nonconformist churches, the questions of access surround the context of the development, the individual community, and the age of the cemetery. Recently, English neopagan groups have also started to express a vested interest in prehistoric human remains, although it is difficult to separate their claims from the rest of British culture of which they are a part.

Forensic Exhumation

Forensic exhumation is the process of investigating mass graves of the recent dead, although it has also been used to describe the archaeological investigation of battlefields and war graves. This is usually used to explain investigations of the victims of massacres, war crimes, or genocide and is particularly applicable to the legal investigations that followed the Guatemala civil war (1960–1996), the Rwandan genocide (1994), and the Kosovo war (1996–1999) and the investigation of the crimes of the Iraqi dictatorship (1968–2006). The methods of forensic investigation are derived from those used in archaeology, which involve site identification using air photographs, ground-based prospection (radar, resistance metering, magnetic sustainability), and excavation. Such activities are intended to assist in identification of the victims of mass murder and the causes of death as well as the events that lead up to it. The aim of this type of investigation is to scientifically document massacre sites and events and is often used to assist in the prosecution of those involved. The methods and skill used in archaeology and forensic archaeology have a wide application; for example, physical anthropologists and archaeologists assisted in the recovery and identification of the victims uncovered during the cleanup of the World Trade Center site in New York.

In summary, exhumation is the act of removing a body from its grave. Some societies practice double funeral rites, but in the West, exhumation is conducted for personal, political, or educational motivations. In the medieval period, pilgrimage to tombs could ensure exhumation of relics, and in the 19th century, fear of exhumation resulted in changes, not just to coffins but also to cemetery organization. Indeed exhumation helped to inspire the birth of a new literary genre and continues to influence it today.

In the modern West, exhumation has been conducted as part of educational investigation and archaeology, and it contributes to the study of human history and the human experience. Archaeology has contributed to the use of exhumation as a legal investigation, but it is not without controversy, especially in the New World, where to indigenous populations, scholars of physical anthropology have been regarded with suspicion and hatred, similar to how the 19th-century resurrectionists were regarded.

Familicide

Taking of the life of a family member—including the killing of intimate partners or spouses, parents killing children, sibling killings, and children killing their parents—is known as familicide. Some researchers define the concept familicide as the killing of an intimate partner but only if the act is accompanied by the killing of at least one child. Such events represent one form of mass killing, an event that often ends with the suicide of the offender. Familial homicide is best understood within the context of domestic violence, of which most killings are committed by the male partner. And while the female homicide offending rate is low, when women do engage in familicide it is usually in response to being a victim of physical abuse.

Familicide Statistics

Since the mid-1970s, federal statistics show that family homicide rates or the number of homicides per 100,000 population in the United States have declined, primarily due to the decreasing incidence of intimate partner homicides. The majority of familicides are committed by male adults, and most of the victims are intimate female partners or spouses. Because federal statistics report the number of homicides by individual victim and offender characteristics, most homicide data involve a comparison of one offender with one victim. Understanding familicide as a mass killing of family members entails using both anecdotal reports from media accounts and the national data. In analyzing such data, it is estimated that approximately one half of all mass homicides committed in the 20th century are related to familicide.

The incidence of family homicide declined during the period from 1976 to 2005. In 1976 intimate killings (killings by partners or spouses) numbered 2,246; by 2005 the number decreased to 810. Children comprise the next largest number of family homicide victims; in 1976 parents killed 551 children and, in 2005 parents killed 470 children. Sibling homicides represent the lowest incidence with 136 killings in 2005, while parental deaths accounted for 271 killings at the hands of their children during that same year.

Demographic Characteristics of Family Killings

In the United States, the majority of offenders and victims are young males, and black victims and offenders are disproportionately represented in national statistics. However, the general pattern of familial homicide trends is similar for both blacks and whites. For other racial and ethnic groups federal reports combine victimization–offending characteristics because these numbers are less than 1% of family homicide annually. However, family violence and family homicide crosses all socioeconomic categories and affects families of all races and ethnicities.

Almost one half of the victims and an equal portion of the offenders were between the ages of

18 and 34 years of age, with 47% and 46%, respectively. Spousal/partner killings are the most common familicides; the next most common are killings of children by their parents. When a child kills a parent, it is most likely a teenage son who kills his father. Teenage or young adult brothers are most often involved in the killing of a sibling; it is extremely rare that a daughter or sister kills either a parent or sibling. Understanding the nature of such information requires some understanding of the dynamic nature of domestic family violence.

Intimate Killing: Women Battering and the Cycle Theory of Violence

Intimate violence is largely unreported in the United States, but for those instances that do receive recognition, the longer a family violence victim stays in the relationship, the greater is the likelihood that she will die a violent death. Although persons of either gender can be a victim of domestic violence, most victims are female. According to the cycle theory of violence, the battering cycle has three phases: tension building, explosion, and loving contrition. First, a batterer is unable to handle life stress and day-to-day problems; as tension builds, the batterer will engage in verbal condescension with the partner. Second, when the tension is too great, the batterer will use physical aggression and violence to release his or her anger. Third, immediately following the explosion, the batterer feels remorse and promises never to hit the victim again. Over time, the cycle will repeat itself with the level and intensity of the violence increasing each time.

Reasons Victims of Family Violence Stay

Victims of family violence tend to believe that the batterer will change and mistakenly think they can change the batterer's behavior. The victim tends to believe she is responsible for the batterer's aggressive behavior; children also believe it is their mother's fault, in turn blaming her for the family problems. As the degree of physical violence increases, victims begin to realize the battering will not end. The batterer is extremely likely to threaten to kill the victim, their children, their pets, and himself if the victim leaves or attempts to leave. At this point, the victim of domestic violence may feel "helpless." Such learned helplessness is the state in which victims of family violence realize that they cannot hide from the batterer. If the victim leaves and is later found by the offender, severe battering results. The victim "learns" to take the abuse. Many victims are isolated from other family members, neighbors, and others who might otherwise assist the victim.

Repeated Family Violence and Homicide

Studies of male homicide offenders conducted during the 1980s and 1990s show that the police were called to homes for family violence numerous times prior to the homicide incident. Often the offender is on probation when the partner is killed. Many partner homicides are committed with the use of a weapon such as a gun, but strangulation is another common method.

Violent episodes seem to be akin to the episodes in which death did not occur. That is, the killing of family members occurs as a part of the battering explosion as opposed to representing a distinct phenomenon. When batterers kill their partner, children, and themselves during the same event, the act of suicide is thought to represent a means by which one escapes being held accountable. This may be a manifestation of one who controls the family outcome as well as his own fate.

Characteristics of Lethal Families

Based on research findings reported during the past several decades, new state and federal criminal justice policies and laws were created to reflect this new knowledge. Psychometric tools also are employed for the purpose of identifying batterers and to respond to victim and family needs. Among the factors that can denote the potential for violence are a prior history of violence, the batterer's jealous or obsessive controlling behavior, prior police visits to the home, prior threats to kill the victim, issuance of an order of protection, threats posed by the victim that she will leave the batterer, use of alcohol or drugs, and threats to commit suicide.

Most offenders are not mentally ill and exhibit normal behavior in the workplace or outside of the home. But it is suggested that one major difference between batterers who kill and those who do not kill may be the availability of, and access to, firearms. For this reason a number of states

prohibit the possession of firearms when a protective court order is in force.

When women kill their partners, it is usually in reaction to a long history of abuse by their partner. But in those states that currently have enacted laws specifically prohibiting domestic violence and also have support systems in place to assist women and children in need, the numbers of partner homicides committed by females have decreased.

Conclusion

Although the prediction of familicide is at best uncertain, the characteristics of women victims killed by a partner are similar to those of other battered women. Agencies usually treat domestic violence cases on a one-to-one basis, although this practice is now under review. Domestic violence laws now reflect the recognition of the great potential for a lethal outcome. Criminal justice agencies in major cities are creating specialized task forces and departments to better respond to the needs of domestic violence victims. In police agencies, domestic violence units handle investigations for severe instances of abuse and work closely with shelters and domestic violence groups. In some cities, there are now domestic violence courts in which a judge handles cases and is able to track repeated violations of orders of protection in order to provide consistent oversight of violators. These practices have been deemed to be successful by victims, practitioners, and agency service providers.

Famine

Famine is an economic and social phenomenon resulting from regional failures of food production or distribution systems and leading to sharply increased mortality. It is evidenced by body weight loss, emaciation, and the weakened condition of the population. Famine can be caused by natural disasters, such as drought or flood; in the modern world, war is its most frequent origin. Death occurs when about one third of the healthy body weight has been lost. The young, small, and highly active die first, and young children who do manage to survive famine often are brain-damaged. Acute starvation also causes depletion of the lymphoid system, so the body cannot produce antibodies and therefore cannot fend off disease. Epidemic diseases found in famine zones include cholera, typhus, typhoid fever, and dysentery. The lack of clean water and medicine exacerbates the situation. In recent times, dictatorships that appear able to afford sophisticated weapons systems and armaments have used famine as a further weapon against their own people. Through examination of a number of historical famines, this entry shows that incidences of starvation are allowed to become famines because of a lack of political will to prevent them.

Physiological and Social Descriptors

Invariably, famine implies starvation, whereas it is not the case that starvation implies famine. Starvation exists where people do not have enough to eat; it does not necessarily mean that there is not enough food available. As people begin to starve, their food requirements decrease because their metabolic rates slow down, and it becomes more

difficult for them to undertake ordinary tasks. In any country that operates a harvest economy, three consecutive bad harvests create famine conditions. It is always a temptation for starving people to eat the following year's seed supply, which fends off immediate starvation but leads to greater problems the following year. Often, the men take food first, and women and children go hungry. Females are able to withstand starvation to much lower body mass indices than are males because females have a greater amount of fat-storing tissue and they use up fat rather than muscle tissue, enabling them to survive.

Although famines appear to be catastrophic events, there are usually signs of impending disaster long before the event itself. Famines are rarely caused by a single factor, either human or natural in origin. Moreover, it is difficult to distinguish between famine and starvation. If food is available in a region, then the incidence of what is known as famine is, in reality, starvation.

The physiological manifestation of starvation may be divided into two main types: marasmus and kwashiorkor. Marasmus is a severe form of malnutrition caused by inadequate intake of protein and calories and usually occurs in the first year of life. The effects on the body are physical wasting and a loss of subcutaneous fat and muscle, resulting in growth retardation. Children who suffer from marasmus display decreased activity, lethargy, apathy, slowed growth, and weight loss. Kwashiorkor is one of the more severe forms of protein malnutrition. Symptoms include weight loss, stunted growth, generalized edema, abdominal swelling, diarrhea, and decreased muscle mass. Both of these forms of starvation are seen during incidences of famine.

To fend off the pains of hunger, starving people often resort to eating tree bark, grass, clay, and other indigestible matter which fills the belly but has little or no nutritional value. The ingested fiber often contains phytates, which reduce the absorption of iron and other minerals from such foods as are available. People who traditionally eat predominantly carbohydrate diets such as potatoes, rice, plantains, and yams find it harder to get the necessary energy requirements and proteins from these foods. Consequently they are often undernourished even in times of good food supply.

History

There are many different causes of famine. Historically famine has been the result of natural disasters: Floods wash away crops; droughts prevent crop growth; volcanic eruptions and earthquakes cause severe disruption; or diseases (such as the fungus *Phytophthora infestans,* which caused the European potato blight in the 1840s) cause crop failures. However in modern times, various human activities have caused most famines. The effects of soil erosion from overcultivation and overgrazing, the destruction of rain forests, and the increase of urban sprawl cause desertification, leading to famine. Overpopulation has also resulted in famine, particularly in third world countries where religious and cultural norms often demand large families. Since 1930, wars or revolutions have led to the destruction of homes and crops, the displacement of populations, and starvation. Political decisions, such as collectivization in the Ukraine in 1932–1933 and China's Great Leap Forward of 1956–1961, have also caused famine.

Ancient Civilizations

The earliest recorded famine occurred in Egypt in about 3500 B.C.E.; another famine in 2180 B.C.E. was caused by a rise in temperatures which, among other things, led to low flood levels on the River Nile. Because Egypt's existence was dependent on the Nile floods, any disturbance to the annual inundation invariably had adverse effects on the Egyptian people. Another Egyptian famine began in 1708 B.C.E. and lasted for 7 years. It is possible that this famine is documented in the biblical story of Joseph, who interpreted Pharaoh's dream warning of 7 years of plenty followed by 7 years of famine.

A famine in Rome in 436 B.C.E. caused thousands of people to throw themselves into the River Tiber rather than await death from starvation. In later Roman history, grain was seen as a form of wealth, which the emperors preferred to hoard rather than provide as food to the starving. Sometimes the Romans were either unwilling or unable to transport vast quantities of grain to needy parts of the empire. Latterly the Roman emperors systematically used the supply or withdrawal of grain as a means of controlling the population. Public order was maintained by

providing "bread and circuses." Between 400 and 800 C.E. the population of Rome fell by over 90%, mainly through famine and plague, brought about by the barbarian invasions.

The Medieval and Early Modern World

Severe droughts hit Central America between 800 and 1000 C.E. These precipitated the collapse of the Mayan civilization, which was unable to function with a reduced population. Those who survived continued as peasant farmers but the glories of the Maya fell into decline. In war-torn, harvest-economy, medieval England there were at least 95 famines, the worst being in 1235 when, in London alone, 20,000 people died. Famine and pestilence laid waste to China between 1333 and 1337. Drought was followed by excessive rains, which caused destructive flooding. A series of natural disasters, plagues of locusts, and the inability of the government to provide aid resulted in the deaths of 4 million people in the lower reaches of the Yangtze River. Famines in China in 1810, 1811, 1846, and 1849 claimed another 45 million lives. The black death, which swept across Europe between 1347 and 1351, is estimated to have killed half the total population, causing the collapse of the agrarian-based society. Survivors were subjected to famine conditions because crops had been neither harvested nor planted during the crisis years.

Later famines were caused by natural disasters. Between 1648 and 1660 Poland lost about a third of its population from war, plague, and accompanying famine. The Scottish famine of the 1690s killed about 15% of its population. In India, the Deccan famine of 1702–1704 saw the deaths of 2 million people, but the first of the Indian famines to attract widespread interest in the Western world was that of 1769–1770. It is estimated that 15 million people—a third of the Bengali population—died. The famine was caused by the failure of the rains, exacerbated by poor administration on the part of the East India Company. In 1783 the Laki volcanic eruption in Iceland resulted in abysmal harvests, leading to a famine that killed about a fifth of the people.

Russia

The Russian people often were ruled by dictators, be they czars or the Communist Party. Famine has also been endemic. Between 971 and 1971 Russia experienced 121 famine years and another 100 hunger years: That is, there was, on average, one hunger/famine year every 5 years. Between 1600 and 1799 this fell to one hunger/famine year in every 3 years. These dates coincide with the little ice-age in the northern hemisphere, when temperatures fell and crops were difficult to grow. The worst period was 1601–1603 when as many as 10,000 in Moscow and a third of the total population died. The same famine wiped out a third of Estonia's population. When hunger is endemic and people live hand-to-mouth, it takes very little to change difficult conditions into disaster. More recently, the great Ukrainian famine of 1932–1933 was the result of Stalin's political will. It was used as a tool to end the newly emerging Ukrainian cultural renaissance and the local resistance to both collectivization and Communism. The Ukraine is famous for its fertile black earth and the volume of grain that can be grown. In 1932 Stalin increased the demand for grain supplies by 44%. He knew that this huge quota would cause such huge grain shortages that the peasants would be unable to feed themselves, but the law was clear: No grain would be provided locally until the peasants had met the quota. Party officials ensured that no grain was hidden and then issued internal passports, preventing Ukrainian peasants from moving elsewhere to find food. Not only grain was taken but also potatoes and beets. It is estimated that between 5 and 8 million Ukrainian peasants starved to death.

Ireland

The potato famine that affected Ireland between 1845 and 1849 led to a 30% fall in the population, caused by the deaths of some 1½ million people and the emigration of a similar number, mostly to America. The fungus *Phytophthora infestans* had spread across Europe before arriving in Ireland. In the peaty, infertile west of Ireland especially, the peasants were almost solely dependent on one potato species: the lumper. In 1845 the fungus wiped out the entire potato crop, precipitating a series of events that led to disaster as it was impossible to eliminate the fungus. The potato harvest failed for 5 consecutive years, destroying the crop that provided about 60% of the nation's food needs.

Technically, the potato famine was not a famine but rather a starvation, since food was available in Ireland and continued to be exported while the peasants starved to death. However, the food gap created by the blight was so huge that it could not have been filled even if all the exported food had been kept in Ireland. By the late 1840s, more food was being imported than was exported and still people starved because they could not afford to pay for it. The United Kingdom's free trade policy prevented the free distribution of food, so public works were established where men were given tasks such as building roads and harbors, filling valleys, and leveling hills to earn money to buy food. However, starving men simply did not have the energy to undertake heavy manual labor, and their efforts to do so increased their metabolic rates, speeding up the rate of starvation.

The price of food in Ireland increased rapidly because grain merchants hoarded it. This put food out of the financial reach of the vast majority of the population. The workhouses could not cope with the influx of paupers, and roads were littered with the corpses of those who had died from typhus and typhoid fever. Independent organizations, particularly the Quakers, set up soup kitchens that alleviated starvation in some areas, but the far west of Ireland was inaccessible and there the people starved. Some landlords, many of whom were Irish, took the opportunity to evict their tenants to undertake land improvement, causing further suffering for those who were starving.

Bengal

The Bengal famine of 1943 resulted in the deaths of about 4 million people. This phenomenon was caused, in part, by high inflation in a war economy and also by rising public spending on military and civil construction. There had been a poor harvest in 1942 following a cyclone, torrential rain, and fungal disease. Japan occupied neighboring Burma and cut off rice exports to Bengal. These factors led to famine conditions followed by high incidences of malaria, cholera, and smallpox. The colonial government prohibited food exports from other, well-provided provinces. This caused another rise in food prices in Bengal, which meant that people could not afford to buy nonessential goods. There was a consequent loss of income for people such as fishermen, landless laborers, and paddy huskers who also found that the real value of their wages had fallen by two thirds since 1940. The situation did not ease until after the end of the war.

China

Between spring 1959 and the end of 1961, approximately 30 million Chinese peasants starved to death, with a similar number of lost births in the worst famine of the 20th century. As in Russia, this famine had ideological origins. Drought was a contributory factor in a country where inadequate water supply is common, but the greatest responsibility has to be borne by Mao Zedong, who launched the Great Leap Forward in an effort to produce vast amounts of steel. The peasants were forced to abandon the land in the frenzy to meet unrealistic demands for steel, which actually turned out to be useless. Concurrently the leaders of the collective farms produced fabricated reports of record harvests. The Party expropriated vast amounts of grain to feed the growing urban populations and to export in order to fund China's nuclear aspirations. In actuality, the grain harvest had collapsed, and the peasants were left with nothing to eat once the government demand for grain had been met. Before 1958 there was sufficient food to feed China's entire population, but by the spring of 1959 there was famine in the rural breadbasket of the country that continued for 3 years. Despite knowing this, Mao did nothing to alleviate the distress of his people.

Africa

In Africa's recent past, most famines have been caused by political upheavals and civil wars. The Biafran war of 1967–1970 was a political conflict caused by the attempted secession of Nigeria's southeastern provinces to create the Republic of Biafra. Nigerian forces surrounded the breakaway area, cutting off supplies. This led to a widespread humanitarian disaster in the besieged areas. It was claimed that to win the war, the Nigerian government used famine as a means of genocide. In Sudan in 1998, famine was a political, military, and economic weapon used by the government and its allies to take control of the oil-rich lands of the

south. To the north of Nigeria is Niger. Conditions there in 2005 initially were no different from other disaster areas in Africa where warning signs are commonplace. Late in the main rainy season of 2004, a plague of locusts invaded the agricultural lands of Niger, causing localized damage. Soon afterward the rains halted abruptly, causing the harvest to fail. Cereal prices started to rise, and although food was plentiful the people could not afford to buy it; these conditions led to a food crisis, malnutrition, and disease, followed by regional famine. The worst incidences of famine came from the relatively wealthier parts of the country: These areas were more densely populated by poor wage-laborers working on cash-crop farms who could not afford to buy food.

Ethiopia has suffered from famines throughout its history. Traditionally, the people live in a subsistence economy in which any surplus food has been taken by the ruling elite. The peasants therefore lack any incentive to improve their agricultural practices. Failure of the rains, plagues of locusts, cattle murrain, and almost constant warfare have caused persistent famines in the country.

Between 1888 and 1892 about a third of the Ethiopian population died, and 90% of cattle died from rinderpest, which was introduced from India. Drought then led to famine conditions everywhere except the southern provinces, which then were attacked by locusts and a caterpillar infestation, destroying the crops. Conditions worsened when cholera broke out; cholera was followed by typhus and smallpox epidemics.

Ethiopia is a poverty-stricken nation where the peasants farm land in unsustainable ways, causing soil degradation. Frequent wars also militate against crop production as soldiers steal any available food. Drought wiped out the 1981 harvest and in subsequent years the spring rains failed and disease destroyed crops. In March 1984 the Ethiopian government said that 5 million people were at risk of starvation because the country could not provide sufficient grain. Meanwhile, the ruling dictatorship spent 60% of the national income on warfare, buying state-of-the-art weaponry to wage civil war against the provinces of Eritrea and Tigre. Foreign governments were reluctant to send aid to a country whose own government was doing nothing to help and which was diverting food aid to feed its troops. Later that year reporter Michael Buerk of the BBC (British Broadcasting Corporation) brought the West's attention to the unfolding Ethiopian disaster. Public donations amounting to £100 million were raised in a few months. Bob Geldoff organized two Live Aid concerts and produced a record that also raised millions of pounds worldwide. Despite every effort, drought and famine are still recurrent problems in Ethiopia, the civil war continues, and the people are poorer now than in 1984.

Conclusion

In November 2001, the UN Food and Agriculture Organization estimated that there were some 815 million chronically malnourished people in the world. More than 30 countries encompassing over 50 million people were facing severe food emergencies. Famines necessarily affect the poorest and least articulate in society, those who have little or no political impact on governments. The modern world is more than capable of producing enough food to sustain its current population of almost 7 billion souls. If the warning signs of famine could be detected earlier (the major cause of food insecurity is war) and if governments and aid organizations could act in concert, without the debilitating effect of corruption, we could eradicate famine.

Fatwa

A *fatwa* is a nonbinding legal opinion within the Islamic legal tradition. The issuance of such legal opinions has its origins in the earliest Islamic period, as jurists among the Companions of the Prophet issued various fatwa to address numerous concerns following the death of the Prophet Muhammad. Fatwa are considered nonbinding because another scholar may come to a different conclusion about a subject, as there is often more than one possible interpretation of the source text.

The terms for independent reasoning (*ijtihad*) and juristic opinion (*fatwa*) are often used interchangeably; however, the critical difference between the two terms is that *ijtihad* has a greater degree of juridical substance and often requires an explanation of its reasoning and evidential basis, whereas a *fatwa* most often consists of a verdict or opinion that is given in response to a particular question. It is not necessary for a fatwa to provide an explanation of its evidential basis; thus, the text of a fatwa may either be very brief or include greater depth and detail.

Fatwa are often sought by individuals who need legal advice in the context of litigation. In such cases, the fatwa may be cursory and brief. When a fatwa addresses complex issues the jurists often feel the need to probe into the course evidence, in which case his finding may be equivalent to ijtihad. Neither the result of ijtihad nor the finding of a fatwa binds the person to whom it is addressed, unless it is issued by a formally constituted court, in which case the decision would carry a binding force.

Ijtihad may only be carried out by a highly qualified legal scholar (*mujtahid*), whereas a fatwa may be issued by a mujtahid or by a scholar of lesser knowledge, though basis in Hadith and narrators of traditions, of the hermeneutics of the Qur'an (*tafsir*), and of the customs and conditions of society must be taken into consideration by anyone issuing a fatwa. For instance, Fatwa issued by prominent scholars and jurists, include Rashid Rida, Abu Zahra (d. 1974), Mahmud Shalut (d. 1970), and the contemporary jurist of the al-Jazeera television network, Yusuf al-Qaradawi. In some cases, fatwa are issued by larger groups such as nongovernmental organizations. In the 1970s, Pakistan gave the process of collective issuance of fatwa a state mandate by forming the Islamic Ideology Council at the government's initiative. Malaysia's National Fatwa Council is a similar statutory body. The various states of Malaysia also maintain fatwa committees that aid the Muftis of each state in their deliberations.

Pragmatism

The creation of large fatwa councils and self-contained Islamic universities also aided the development of new methods of teaching and scholarship in relation to legal opinions and reflect the pragmatism of defining Islamic law. Interpretations of Islamic law have frequently made concessions to the sick, the elderly, pregnant women, and travelers, as well as others who face hardship regarding daily prayers and fasting. It also makes provisions for emergencies, in which the rules of Shari'a may be temporarily suspended on grounds of necessity. Thus, the fatwa of a mujtahid must take into consideration changes of time and circumstance. For instance, people were not allowed in the early days of Islam to charge a fee for teaching the Qur'an, as this was an act of spiritual merit. Later, it was noted that people no longer volunteered to teach, and knowledge of the Qur'an declined. The jurists consequently issued a verdict that reversed the former position and allowed payment of remuneration for the teaching of Qur'an. Note also the pragmatic verdict of Imam Malik of the 10th century, which permitted the pledging of allegiance (*bay'a*) for the lesser qualified of two candidates for leadership, if this is deemed to be in the public interest.

The same logic can be applied to the uprightness of a witness. In more modern times, national fatwa councils introduced research-oriented scholarship to take into consideration not only the traditional subjects, but also new areas such as the Islamic law of obligations, Islamic constitutional law (*al-fiqh al-dusturi*), Islamic economics, Islamic banking and finance, and human rights studies. In a more recent development the introduction of fatwa councils in major banks and financial institutions, which are charged with the task of ensuring compliance with the Shari'a in banking operations, has become commonplace.

Enforcement

Despite the flexibility of interpretation within Islamic legal opinions and the nonbinding nature of a fatwa, there are required source texts that each fatwa ought to address. The source text for a fatwa are first the Qur'an, as it is the highest authority, and then the Sunna. If an issue is not clearly addressed in the Qur'an or the Sunna, the jurist then looks to see if there is any consensus among the scholars concerning the matter. If no clear proof is found in any of these three sources, then the jurist exerts all intellectual and spiritual efforts to arrive at a sound position that is consistent with the goals of the Sacred Law, through analogy or one of several other legal considerations. These considerations include analogical reasoning based on existing texts, equity, public good, permissibility, and precedents.

Moral Versus Legal Obligations

The distinction between moral and judicial obligations also characterizes the difference between adjudication (*qada*) and fatwa. The judge (*qadi*) must decide his cases based on apparent evidence, whereas a jurisconsult (*mufti*) investigates both the apparent and the actual positions. Both are reflected in the verdict. In the event of a conflict between the two positions, the mufti can base his fatwa on religious considerations, whereas the judge must consider objective evidence only. Hence, a pious individual in a court case is not treated differently from a person of questionable piety or of no apparent religion.

This distinction has allowed for a changing nature of the fatwa. The Islamic jurist Shafi'i (767–820 C.E.) maintained that a mujtahid should not hesitate to change a previous ruling (fatwa) if this would make a better contribution to the quest for truth. Thus, Shafi'i frequently changed his own verdicts and sometimes recorded different rulings on the same issue. For example, if a man deceives a woman he marries by claiming a false family pedigree, he is liable to punishment. Shafi'i had two separate views on this subject, but neither is given preference over the other. The first view entitles the wife to choose to either continue the marriage or separate. The second view rules that the marriage is void. Shi'ite jurists have adopted Shafi'i's views and recognize that in the absence of the Hidden Imam, the contemporary jurisprudence, which serves to as a stand-in for the Imam, can, in fact, override the fatwa of his predecessors.

Food Poisoning and Contamination

Food poisoning, which is also called food-borne disease and food-borne illness, is a term used to describe illness resulting from the consumption of contaminated food. This entry provides general information on food poisoning and contamination, including symptoms and a discussion of common food contaminants. Food poisoning is a common, sometimes mild and sometimes life-threatening problem for millions of people around the world every year. Although there may be no symptoms in some cases, symptoms may range from mild intestinal discomfort or nausea to severe diarrhea or even dehydration. Depending on the type of contaminant, fever, chills, bloody stools, dehydration, nervous system damage, or even death may occur as a result of food poisoning. Cases where two or more people become ill as a result of consuming the same food are called outbreaks.

True food poisoning occurs as a result of ingesting a contaminating chemical or toxin, while most cases of food-borne illness are caused by food-borne bacteria, viruses, prions, or parasites that contaminate food. Food-borne illness generally results from poor sanitation or the improper handling, preparation, or storage of food. Following good hygiene practices before, during, and after food preparation can reduce the probability of contracting a food-borne illness. Food handlers who have infections or do not wash their hands after using the bathroom may cause contamination, and improperly packaging or storing food can also lead to contamination.

More than 250 different diseases can be transmitted through foods, most of which are infections caused by a variety of parasites, viruses, and bacteria that can be food-borne. According to a report by the Centers for Disease Prevention and Control (CDC), unknown or undiscovered agents cause 81% of food-borne illnesses and related hospitalizations. However, many cases of food poisoning are unreported because the symptoms are mild and victims may recover quickly. Also, doctors do not test for a cause in every suspected case of food poisoning because it would not change the treatment or outcome.

According to CDC estimates, food poisoning causes about 76 million illnesses, 325,000 hospitalizations, and up to 5,000 deaths each year in the United States. Visitors to developing countries often encounter food poisoning in the form of "Montezuma's revenge" or "traveler's diarrhea," and diarrheal illnesses are among the leading causes of death worldwide. In addition, there are new global threats regarding the contamination of the world's food supply through terrorist actions, using food toxins as weapons.

The types of food-borne diseases affecting humans constantly change over time. Common food-borne diseases a century ago, including typhoid fever, tuberculosis, and cholera, have been controlled as a result of improvements in food safety, such as the pasteurization of milk, proper canning, and disinfection of water supplies. Other food-borne infections have taken the place of these diseases of the past, and new food-borne infections continue to be discovered. These new diseases emerge because contaminating agents can easily spread around the world and evolve, the environment and ecology change, food production practices and consumption habits change, and better laboratory procedures make it possible to identify previously unrecognized agents.

The "acceptable daily intake" levels and tolerable concentrations of contaminants found in individual foods are determined by conducting animal experiments that provide a safety factor based on "no observed adverse effect level." The U.S. Food and Drug Administration (FDA) oversees the maximum concentrations of contaminants allowed in foods, with the maximum concentration often being well below toxicological tolerance levels. The amount of an agent that must be consumed to lead to symptoms of food-borne illness is the infectious dose, which varies based on the agent and the consumer's age and health.

Symptoms

The different harmful agents found in foods and water lead to many different symptoms, so there is no single set of symptoms for food-borne illness. Food-borne illness is typically evident when uncooked or unprepared food is consumed, and symptoms of food-borne illness generally occur within 48 hours after consuming a contaminated food or beverage. The delay between consuming a contaminated food and the appearance of symptoms, which ranges from hours to days or even months or years in rare cases, is called the incubation period. The incubation period depends on the agent and the amount consumed. Having symptoms that occur within 6 hours after consumption of a food indicates that the food-borne illness is caused by a bacterial toxin or chemical rather than live bacteria. During the incubation period, microbes pass through the stomach and into the intestine, attaching to the cells lining the intestinal walls and multiplying. Some agents stay in the intestine, some produce a toxin that is absorbed into the bloodstream, and others directly invade deeper body tissues. Symptoms are dependent on the type of agent consumed.

Depending on the agent involved, symptoms can include one or more of the following: nausea, abdominal pain, vomiting, diarrhea, gastroenteritis, fever, headache, or fatigue. The body is able to permanently recover after a short period of illness in most cases. Certain groups, including babies,

young children, pregnant women and their unborn children, the elderly, and those who are sick or have weak immune systems, are more likely to face permanent health problems or even death. Foodborne illness may also cause reactive arthritis, which generally occurs about 1 to 3 weeks afterward. Symptoms of Creutzfeldt-Jakob disease, which is usually transmitted by eating beef from cows with bovine spongiform encephalopathy (also called mad cow disease), differ from bacterial food poisoning and appear after many years. After symptoms appear, the disease is fatal.

Food Contamination

There are two categories of known food poisoning agents: infectious and toxic. Some of the most common infectious agents are those caused by bacteria, including botulism, *Campylobacter, Salmonella, Staphylococcus aureus, Shigella,* and *E. coli,* as well as a group of viruses called calicivirus, which are also called Norwalk and Norwalk-like viruses. Infectious agents also include parasites.

Botulism

Botulism is caused by *C. botulinum,* which is unlike any of the other food-borne bacteria in that it can only live in the absence of oxygen and includes neurotoxins that poison the nervous system and lead to paralysis without the vomiting and diarrhea associated with other food-borne illnesses. Botulism is much more likely than other infectious agents to be fatal, even in tiny quantities. Botulism outbreaks are generally associated with home-canned food, although commercially canned foods are occasionally responsible for the disease. Symptoms of adult botulism appear about 18 to 36 hours after the contaminated food is consumed and begin with the person suffering from weakness and dizziness with double vision. Symptoms progress to difficulty swallowing and speaking, with paralysis moving down the body. Those showing signs of botulism must receive immediate emergency medical care to increase the chances of survival.

Campylobacter Jejuni (C. jejuni)

The FDA reports that *C. jejuni* is the leading cause of bacterial diarrhea in the United States. Although anyone can get food poisoning from this agent, children under age 5 and young adults between the ages of 15 and 29 are more frequently infected. *C. jejuni* is carried by healthy cattle, chickens, birds, and flies and is also found in ponds and stream water. Symptoms of food poisoning from *C. jejuni* generally begin 2 to 5 days after eating contaminated food, with symptoms including fever, abdominal pain, nausea, headache, muscle pain, and diarrhea. Symptoms last from 7 to 10 days, and relapses occur in about one quarter of those infected.

Salmonella

Between 2 and 4 million cases of food poisoning from *Salmonella* are estimated to occur each year in the United States. *Salmonella* is found in raw and undercooked poultry and meat, dairy products, fish, shrimp, egg yolks from infected chickens, and other food products. The CDC estimates that 1 out of every 50 consumers is exposed to a contaminated egg yolk each year, but thoroughly cooking eggs kills the bacteria, leaving the food harmless.

Staphylococcus Aureus

Staphylococcus aureus is found in environmental dust, air, and sewage, as well as on the human body. It is mainly spread by food handlers following poor sanitary practices. Foods kept at room temperature are more likely to be contaminated. Symptoms of *Staphylococcus aureus* are similar to those caused by other food-borne bacteria, with many cases being very mild and not requiring physician care. Symptoms generally appear within 6 hours after the contaminated food is consumed, with acute symptoms including vomiting and severe abdominal cramps without fever, usually lasting 3 to 6 hours and rarely more than 24 hours.

Shigella

Shigella is associated with contaminated food and water, poor sanitation, and crowded living conditions. Among travelers to developing countries, *Shigella* is a common cause of diarrhea. The bacterial toxins affect the small intestine, with symptoms of food poisoning by *Shigella* occurring 36 to 72 hours after consumption. Symptoms

differ slightly from those associated with other food-borne bacteria, with nausea, vomiting, abdominal cramps, chills, and fever occurring in addition to diarrhea. Children with severe infections may show neurological symptoms, including seizures caused by fever, confusion, headache, lethargy, and a stiff neck, resembling meningitis. The disease generally lasts 2 to 3 days but may last longer.

Escherichia Coli (E. coli)

Many strains of *E. coli* exist, and not all are harmful. The strain causing the most severe food poisoning is *E. coli 0157:H7*. Food-borne *E. coli* is transmitted mainly in food derived from cows, such as raw milk and raw or rare ground beef, as well as fruit or vegetables that are contaminated. Symptoms of food poisoning from *E. coli* appear more gradually than those caused by other food-borne bacteria, as it produces toxins in the large intestine rather than higher up in the digestive system. One to three days after eating the contaminated food, the individual begins to have severe abdominal cramps and watery diarrhea that becomes bloody within 24 hours. There is little or no fever, and vomiting is rare. The bloody, watery diarrhea lasts 8 days or less in milder cases.

Calicivirus

Calicivirus is a common cause of food-borne illness but is rarely diagnosed because the laboratory test is not widely available. The ingestion of this agent leads to an acute gastrointestinal illness, generally causing more vomiting than diarrhea, and ends within 2 days. It is believed that these viruses primarily spread from one infected person to another, unlike many other food-borne agents that are transmitted through animals and animal products. Infected individuals can also transmit the virus to other individuals when processing or preparing foods.

Toxic Food Contamination

Food poisoning caused by toxic agents occurs when there are harmful chemicals or toxins in a food, such as poisonous mushrooms, improperly prepared exotic foods, or pesticides on fruits and vegetables. Chemical contaminants in food often visibly affect consumer health and well-being only after several years of prolonged exposure at low levels, manifesting in diseases such as cancer. Whereas most microbiological agents are affected by thermal processing, chemical contaminants are not.

There are several types of chemical contaminants, which are classified by their source and the way they enter food products. Environmental contaminants are chemicals within the environment in which the food is grown, harvested, transported, stored, packaged, processed, or consumed. These can be chemicals found in the air, water, soil, packaging materials, or processing equipment. Chemicals that are intentionally added to foods during processing, generally for economic, nutritional, or safety reasons, are called food additives. The use of food additives in a manner inconsistent with their intended use can result in undesirable levels in the finished product, possibly exerting unfavorable effects on the food product or consumer health. Processing contaminants are generated while foods are processed, forming as a result of chemical reactions between natural and/or added food elements during processing. Trans fat is an example of a processing contaminant. Agrochemicals are used in agricultural practices and the practice of breeding and raising livestock. These include pesticides, veterinary drugs, plant growth regulators, and bovine somatotropin.

Forensic Anthropology

In 1977 the American Board of Forensic Anthropology was established, and in the year 2007 there were over 70 certified diplomates. Forensic anthropology has evolved into a legitimate discipline and has become a part of American popular culture as evidenced by the proliferation of novels and television programs featuring forensic anthropologists.

The primary definition and focus of forensic anthropology involves the discovery, recovery, examination, and analysis of human skeletal remains in a legal investigation or in a humanitarian situation as performed by physical anthropologists trained in anatomy, osteology, pathology, and odontology. The origins of forensic anthropology can be traced to the work of medical doctors and human anatomists who, upon looking at a cadaver, tried to determine the sex, age, stature, ancestry, and in some cases cause of death. History is filled with the names of anatomists and physicians who stood ready to question the cause and manner of death and identity of an individual. Even Paul Revere identified a set of dentures found in an exhumation, made of hippopotamus teeth and silver wire that he himself had made for the deceased Dr. Joseph Warren who was killed at the battle of Bunker Hill and buried in an unmarked grave by the British. This identification enabled Dr. Warren to be reburied as a hero.

The earliest progenitors of modern forensic anthropologists were individuals who practiced chemistry, anatomy, and medicine who also were interested in archaeology. Offering to assist in the study of skeletons of prehistoric Native Americans, one such individual, Joseph Jones, investigated the prehistoric Native American remains from stone box graves in Tennessee. This early examination of skeletal remains included the measurement of crania and comparison of these measures to cranial measurements provided by Samuel George Morton's earlier efforts. More importantly, Jones noted cultural modifications of the skeleton and described the pathology present on the bones, even making thin sections of bone to analyze bone microstructure. During the 1920s anatomist T. Wingate Todd of Western Reserve University would further advance the development of forensic anthropology by continuing the work of Carl August Hamann in assembling a collection of human skeletons from modern cadavers; this collection now numbers well over 3,000. Each skeleton was examined with sex, age, stature, and ethnicity noted. Data on the individual's birthplace, occupation, and probable cause of death also were recorded, and photos of the cadaver taken prior to dissection were included in each skeleton's file. This collection was to prove useful in developing a standard for looking at the changes on the surface of the pubic symphysis of the pelvis and the degree of suture closure on the cranium to determine age at death.

Much of the early development of forensic anthropology started in the 1930s and 1940s, with continued analysis of Native American skeletons by physical anthropologists associated with museums and those associated with Franklin D. Roosevelt's New Deal programs. Physical anthropologists practiced forensic techniques on Native American human skeletal collections, but rarely were these individuals asked to help in a forensic investigation including skeletal remains. Charles E. Snow, however, attempted to replicate prehistoric Native American cranial deformation using the head of a modern cadaver.

In 1939, Wilton M. Krogman published an article on identifying human skeletal remains in the *FBI Law Enforcement Bulletin*, and this publication would soon lead to an ever-increasing role of physical anthropologists in criminal investigation. Later, Krogman's book *The Human Skeleton in Forensic Medicine* would become the standard textbook for the study of forensic medicine.

World War II and the conflicts in Korea, Vietnam, Iraq, and Afghanistan have all increased the need for forensic anthropologists who, in turn,

have refined their methodology. In 1947, a laboratory was established in Hawai'i to identify casualties from World War II. A representative from the Smithsonian Institute, anthropologist T. Dale Stewart, assisted in providing identifying information for both the U.S. government and the Federal Bureau of Investigation. Based on these experiences Stewart edited a volume titled *Personal Identification in Mass Disasters* in which further refinement of aging, sexing, and stature methods are found. "Mass disasters" would prove to be prophetic, as forensic anthropologists began to assist in identifying those who died as a result of terrorist activities, plane crashes, space shuttle explosions, war atrocities, mass graves, and genocide. Today forensic anthropologists are counted among the members of the national Disaster Mortuary Operational Response Team.

A physical anthropologist at the University of Tennessee, William Bass, made the identification of human remains more easily understood through classroom instruction and archaeological fieldwork through the creation and subsequent update of a manual that included drawings for identifying bones and all the requisite standards for evaluation of aging, sexing, and determining stature of a skeleton. Today forensic anthropologists are involved in the recovery of crime scene data ensuring the security of such data. And in places such as "body farms," donated cadavers are placed in different environmental conditions (buried or unburied) and the decomposition of the remains is monitored as to a body's taphonomy (modification of remains after death by animals and natural forces and elements), entomological interaction, and relationship with botanical species. Information pertaining to postmortem interval or time since death is quite valuable within the judicial system.

The work of forensic anthropologists encourages the development of better analytical techniques to determine the age of fetal, infant, and child skeletal remains. Much of the work on the appearance and characteristics of violent, accidental, occupational, and chemical bone trauma is through the analysis and experimental work of forensic anthropologists, some of whom use facial reproduction to identify previously unknown skeletons.

Forensic anthropologists also contribute to the investigation of a crime scene where a fire has occurred through a protocol for search and recovery of the cremated remains. New methods of analysis of the effects of fire on bone also have evolved through these experiences. Perhaps even more valuable is the work that distinguishes whether evidence of inflicted violent trauma found on cremated bone was perimortem or postmortem.

Forensic Science

Forensic science is a broad field, encompassing a range of sciences, that exists to meet the demands of the legal system. It emerged as a distinct field in Europe and the United States at the end of the 19th century in response to legislative changes that increased the status of evidence over and above testimony. The shift toward evidentiary trials called for a class of experts able to identify, collect, and document evidence left at crime scenes. In cases of suspicious death, their expertise extended to the study of the corpse in order to make formal identifications and secure evidence to assist the investigative process. Forensic science is, therefore, a specialized knowledge that is intimately connected with death and, since its rise in the 19th century, has shaped the law, reinforced the value of evidence, and mediated cultural attitudes toward human remains. Further, the cultural and political role of the dead body itself has been transformed as a consequence of the power

of forensic technologies to invest it with a singular truth-telling power.

From Sherlock Holmes to *CSI*

The detective novel developed as a genre in the 19th century alongside forensic science and played a crucial part in educating the public about the potential for the new science to assist law enforcement agencies. Famously, Arthur Conan Doyle's fictional detective, Sherlock Holmes, adopts a forensic approach to solve mysteries and track down criminals, and he is often seen analyzing footprints, fingerprints, and other trace evidence left at crime scenes. Not only did Doyle's narratives help to popularize scientific theories and techniques, but on occasion they even anticipated the use of procedures in scientific police practice. Their fantasies of social control created a fecund ground for the eventual adoption of the actual technologies, such as fingerprinting.

This entanglement of forensic science with narrative is not unique to the fin de siècle but is a notable feature of the 20th and early 21st centuries. For example, novels by Patricia Cornwell center on a forensic scientist, the Chief Medical Examiner Kay Scarpetta, and the U.S. television series, *CSI: Crime Scene Investigators* and its spin-off shows have achieved global popularity. Forensic science—its empirical methods and technologies—is, thus, peculiarly resourceful for crime narratives and, in turn, such narratives help legitimize it, raising its profile and rendering it accessible to a wide audience. It therefore stands out from other sciences, whose purposes and practices remain more obscure for the public, as a result of the prominent position it holds in popular culture. In fact, the prevalence of forensic science in fiction and television dramas has given rise to a condition termed the "CSI effect." This refers to the public's raised expectations of the field in legal situations, national and international, in turn contributing to further increasing the status awarded to material evidence in trials and bolstering the authority of forensic scientists.

Undoubtedly, one of the main factors determining such an abiding and widespread cultural interest in forensic science is its unique power to make sense of suspicious deaths. Although it is an ever-expanding and evolving field, including specialist areas as diverse as ballistics and entomology, autopsy is, perhaps, the practice that has come to epitomize it in the popular imagination. An autopsy is a medical procedure conducted by a pathologist involving the examination of both the exterior and interior of a corpse to determine the cause of death. Hence, a degree of ambivalence surrounds the forensic pathologist: His or her knowledge can assist criminal cases and grieving families, yet it is acquired by transgressing cultural taboos, violating the body, and awakening age-old fears of interiority. The popular interest in forensic science is a feature, therefore, of a broader fascination with the corpse and transgression of the body's boundaries, with expressions of the provisionality of identity. It is also a manifestation of an intense cultural desire to explain suspicious deaths. Forensic science offers the hope that the dead have not died in vain by paving the way for greater understanding of particular medical conditions and for justice.

Notwithstanding its unique role in making sense of suspicious deaths, forensic science overlaps with a number of other scientific disciplines besides medicine, such as biochemistry, biology, and bioinformatics, and cannot be considered in isolation from them. The roles associated with the field also vary widely, as does the training required to perform them. To illustrate, scene-of-the-crime investigators in the United States (scenes-of-crime officers in the United Kingdom) receive on-the-job training to enable them to gather and document forensic evidence, whereas to become a forensic pathologist a considerable amount of training following a degree in medicine is required.

Forensic experts—in particular, forensic pathologists—mediate between the dead and the public. They claim to speak on behalf of the dead and, by disclosing the secrets of their final moments, offer hope to sustain the living. For the victim's relatives, knowledge of the cause of death can help in the grieving process and, in criminal cases, it is pivotal to the process of discovering the identity of perpetrators and is used as evidence in court. In view of the taboos broken by pathologists in their examination of the dead and their transformation of human remains into evidence, it is vital that they legitimate their role; this is achieved, in part, by appealing to the metaphor of speaking for and listening to the dead. This rhetoric of communion

with the dead is especially prevalent in forensic narratives and television dramas. Patricia Cornwell's fictional medical examiner, for instance, frequently draws attention to her special ability to listen to the testimonies of the dead and interpret their messages for both their relatives and the courts.

Over the course of the 20th century, forensic science increased its sphere of influence to intervene in international political and judicial affairs. Its capacity to read the truth about the past in the bodies of victims renders it a powerful tool in investigations into human rights abuses. In the 1980s, the American forensic anthropologist Clyde Snow helped to establish the field in human rights contexts as a result of his work exhuming mass graves in Argentina, Guatemala, and Croatia, among other places. By identifying the dead and establishing the cause of death, forensic scientists are able to provide evidence to convict perpetrators and challenge the historical accounts of political authorities, thus empowering victims and their communities. In addition to the legal value of forensic expertise for human rights organization, it is often privately welcomed by victims' relatives as it helps the mourning process. Without a name, a body cannot become evidence in tribunals to convict perpetrators nor can it be restored to its family for traditional funeral rites.

Forensic science is of interest, as its practitioners are legally empowered to decipher the bodies of the dead to provide accounts of the past. Forensic science has come to occupy a prominent place in the media and popular culture, inflecting the public's relation to the dead body and sustaining the hope of justice.

FRANKENSTEIN

On June 16, 1816, Mary Wollstonecraft Shelley created one of the enduring myths of modern civilization: the narrative of the scientist who single-handedly creates a new species, a humanoid form that need not die. In her novel *Frankenstein, or The Modern Prometheus* (1818), Victor Frankenstein robs both cemeteries and slaughterhouses in order to suture together a creature composed of dead animal and human body parts, a creature he then animates with the "spark of life." In doing so, he claims he has renewed life where death had apparently devoted the body to corruption. Frankenstein thus realizes the age-old wish of mankind to transcend mortality, to become a god. And like Prometheus, who in ancient myth shaped the human species out of clay and then stole fire from the Olympian gods to give to man, Victor Frankenstein expects to be revered, even worshipped.

But in his hubristic quest to become God, to create an immortal race, Frankenstein constructs a monster that eventually destroys his wife, his best friend, and his baby brother; these events so exhaust Frankenstein that he dies at an early age. Mary Shelley's novel has thus become the paradigm for every scientific effort to harness the uncontrollable powers of nature and the unintended consequences those efforts have produced, be they nuclear fission, genetic engineering, stem-cell cloning, or bioterrorism. The popular conflation of the scientist *with* his monster—such that "Frankenstein" is as often the name of the creature as of his maker—only points to a profound understanding of Shelley's novel in which Victor Frankenstein finally becomes as filled with hatred, revenge, and the desire to destroy as the creature he hunts across the Arctic wastes.

How did the 18-year-old Mary Wollstonecraft Godwin (later Shelley) come to write such a prescient tale of modern science? Two years earlier, on

July 28, 1814, Mary had eloped with the poet Percy Shelley to France. Seven months later, Mary gave birth prematurely to a baby girl, called Clara, who lived only 2 weeks, after which she had a recurrent dream that her little baby came to life again, that it had only been cold, and that she had rubbed it before the fire, and it had lived. Immediately pregnant again, Mary gave birth to her son William on January 24, 1816. Four months later, Mary, Percy, and Mary's stepsister Claire left England to join Claire's new lover, Lord Byron, in Geneva. Kept indoors by the coldest summer in a century following the eruption of the volcano Tamboro in the Indonesian archipelago in April (which threw so much debris into the atmosphere that the sun was literally blocked out), reading ghost stories for their amusement, the four friends decided on June 16, 1816, to have a contest in which each would compete to write the most frightening story.

That night Mary had the "waking dream," or reverie, which provided the germ of *Frankenstein*. Born from Mary's own deepest pregnancy anxieties (What if I gave birth to a monster? Could I ever wish to kill my own child?), her novel brilliantly explores what happens when a man attempts to have a baby without a woman (Victor Frankenstein immediately abandons his creature); of why an abandoned and unloved creature becomes a monster; of the predictable consequences of her day's cutting-edge research in chemistry, physics, and electricity (most notably the experiments of Erasmus Darwin, Humphrey Davy, and Luigi Galvani); and of the violent aftermath of the French Revolution. Psychologically, Mary draws directly on her own childhood experiences of isolation and abandonment after her mother's death in childbirth and her father's remarriage to a hostile stepmother to articulate Frankenstein's creature's overwhelming desire for a family, a mate of his own, and his subsequent violent anger when he is rejected by all whom he approaches, even his maker. By including an image of the murder of her own son William in the novel, Mary articulated her deepest fear that an unloved (and psychologically abused) child, such as she herself had been, could become an unloving, abusing mother, even a murdering monster.

The novel focuses as powerfully on the dangers of science as on Frankenstein's failure to mother his creature. Here Mary invokes her considerable knowledge of recent scientific experiments by Luigi Galvani (whose nephew, in a particularly famous experiment carried out in London in 1803, electrified the body of a recently hung criminal in an attempt to prove that electricity is the life force) to suggest that Frankenstein's success in bringing a creature back to life with a spark of "fire" (both the mythic fire that Prometheus stole from the gods and a spark of electricity) was entirely possible. But Frankenstein's attempt, in Mary's view, violates the laws of nature, of natural modes of procreation and reproduction; he is therefore pursued and punished in the novel by Mother Nature, who curses him with physical and mental disease, denies him a maternal instinct and the opportunity for natural procreation (his creature kills his bride on his wedding night), pursues him with the very lightning he has stolen from her, and finally brings about his death from natural causes at the age of 26. Worse, in his eagerness to work with bigger, simpler pieces, Frankenstein has constructed a creature of superhuman size and strength, one capable of wreaking havoc on the human race. As the creature tells Frankenstein, "You are my maker, but I am your master—obey!"

As *Frankenstein* finally shows, an unmothered child, like a scientific experiment performed without consideration of its probable results, like a political revolution set in motion without control over its participants, can become a monster, one capable of destroying its maker. Implicitly, the novel endorses instead a science that seeks to understand rather than to change the workings of nature, a politics of evolutionary reform rather than sudden revolutionary change, an ethic of care that would attend to the needs of all the members of the body politic. In this way, Mary follows the feminist politics of her mother Mary Wollstonecraft, endorsing her belief in a family politics, in the model of a loving, egalitarian family that can incorporate and serve creatures of every race and size (imaged in the novel in the French De Lacey family and their welcomed Arab guest Safie) as the blueprint for gradual social reform.

Freudian Theory

Freudian theory is a covering term for work in a variety of fields that use key components drawn from Sigmund Freud's conceptual framework. It is not obvious just how Freudian a theory has to be in order to qualify. Freudian theory is linked to the themes of death and dying through Freud's later work, in particular *Beyond the Pleasure Principle* (1920) and *Civilization and Its Discontents* (1930), in which he advanced and then developed the controversial claim that humans have a death instinct (*Todestriebe*).

In *The Interpretation of Dreams* (1899) Freud had little to say about death. In this book Freud treats dreams as representations of the fulfillment of wishes and holds that this provides a pathway toward an understanding of the unconscious. The wishes that are fulfilled in dreams are taken to be, in many cases, sexual in nature, albeit their sexual content tends to be latent or disguised. Wishes are fulfilled in dreams because they cannot be allowed to dominate waking life. In this way, desires of a problematic sort are held in check. However, the relation between desires and constraint or repression is a complex one. We are more likely to have our desires gratified if we can at least delay their fulfillment. Our lives are structured by a pleasure principle and a reality principle, with the latter constraining the former. The reality principle tolerates delays and can redirect our energies into other channels. Dangerous or socially unacceptable desires are repressed and resurface in other guises.

Patterns of repressed and concealed desire become sedimented during infancy and then exert an influence in later life. Most notoriously, a normal pattern of sexualized male attachment to the mother and rivalry with the father can shape an entire life. Explanations of this sort focus upon personal history. They appeal to the idea that humans are the product of their past. That is, they appeal to prior causes rather than end states. Part of the role of therapy is to exert some control over the often unacknowledged influence of the past by bringing it to light. Insofar as death lies in the future, this approach leaves no room for death to play a significant role. Desires of a sexual nature become sedimented in infancy because infants are (in some broad sense) already sexual beings. Desires concerning death cannot do so because children, according to Freud, have no real grasp of death. Children equate death with someone having "gone away." For death to become significant, it would have to amount to a return to some prior condition.

The Death Instinct

Whatever the limitations and problems of Freud's early approach, the idea of the unconscious opened up an important possibility. If our mental life is not transparent, then we may be covertly drawn toward death even while consciously professing hostility and alarm at the prospect. There are some indications that Freud was already leaning toward this view prior to World War I. Immediately after the conflict he published *Beyond the Pleasure Principle*, in which he claimed that the pleasure principle and the reality principle were not deeply opposed to each other because both ultimately operated in the service of the reduction of tension. Both were geared toward the same end.

In place of the previous opposition, Freud situated a life-and-death struggle at the center of a new account of our conflicted nature. A sexual life instinct (Eros) moves us to reproduce and to guarantee survival. Set against it is a death instinct that moves us to *return* to an earlier condition of tension-free stability. Desire here is taken as a state of uneasiness that we want to be rid of. This account allows the return to and mechanical repetition of the past to be brought into harmony with a more teleological (end-driven) orientation toward our future demise. What we are driven toward is not just any sort of death but only the right kind of death, one that is a return and is tension-resolving. We strive to fight off obstacles on the way to the latter. As a result, the death instinct can help

prolong life by leading us to adopt a self-defensive posture when threatened.

Aggression is generally to be understood as the death instinct directed outward toward others as obstacles. Self-destructive behavior, by contrast, is to be understood as the death instinct directed inward toward the self as an obstacle to the right kind of death. These two can be traded off against each other on both an individual and a broader social scale. The aggression and self-destructiveness of individuals are related. So too are war and national aggression. They can be a nation's way of avoiding self-destructive internal feuds by redirecting their energies elsewhere. This rather sanguine view of the death instinct was developed in more detail in *Civilization and Its Discontents*.

Reception of the Theory Among Freudians

One qualification that is frequently made is that the translation of *Trieb* as "instinct" is misleading and that "drive" might be more accurate. Unlike instincts, *Triebe* are influenced by the social environment and are not biologically predetermined. A death drive that is not a biological given may be shaped or transformed. The energies that it draws from might be channeled in some more productive way. Freud's own views on this matter are unclear.

Among orthodox Freudians the reception of the Todestriebe was mostly critical. Otto Fenichel claimed that appeal to a death instinct was not necessary or useful. In *The Psychoanalytic Theory of Neurosis*, Fenichel acknowledged that it made sense to think of life as a process that led to death, but the positing of an actual death instinct was not needed to make sense of aggression and self-destructiveness. It was, instead, an interesting metaphysical conjecture. As such, its clinical-therapeutic implications were unclear. Less orthodox Freudians argued that Freud had confused the genuine destructiveness of humans under capitalism with the human condition as such. A significant part of the subsequent history of Freud's death instinct is its appropriation by critics of capitalism rather than its use as a diagnostic tool for clinical practice. Marxists in particular have been keen to exploit the analogies between the death instinct and the seeds of self-destruction that they take capitalism to contain. In our own self-destructiveness and aggression, we mirror the capitalist system.

Freud's death instinct had some early champions within the psychoanalytic community, but even the best-known defenses diverged from Freud in significant respects. The American psychoanalyst Karl Menninger claimed that each man tried to kill himself in his own peculiar way. But Menninger's account, in *Man Against Himself*, was fairly upbeat in a way that Freud's account never was about the possibility of channeling the energy that went into self-destructive behavior (and suicide in particular) in more productive ways. Willhelm Stekel was supportive but presented a darker picture of the Todestriebe. In particular, he focused on the concept of Todestriebe as a way to displace a good deal of Freud's sexualized account of desires.

Post-Freudians: Klein, Marcuse, and Lacan

When the Todestriebe resurfaced as a major theme in the postwar years, it shaped both clinical practice and social theory. Melanie Klein pioneered the extension of psychoanalytic therapy to children and was firmly of the opinion that infantile aggression and envy in later life were linked to the self-destructive death drive. Her work, while focusing upon children and so restricted to one class of therapeutic subjects, goes some way to answering Fenichel's charge that the Todestriebe has no clear clinical-therapeutic implications.

By contrast, the appropriation of the Todestriebe by Herbert Marcuse and Jacques Lacan lends some support to Fenichel's concern that this is not really a suitable or necessary diagnostic tool. Marcuse was a social theorist of the Frankfurt School, while Lacan was a psychoanalyst. But Lacan's focus was more theoretical than clinical. Both explored the Reichian claim that there was an intimate connection among capitalism, repression, and self-destructiveness.

Whereas Freud had claimed in *Civilization and Its Discontents* that repression was a necessary and socially beneficial way of holding our destructiveness in check, Marcuse linked repression closely to the destructive impulse. In the influential *Eros and Civilization* (1955) he argued that the political struggle against capitalism was the struggle for Eros against Thanatos, life against death. A nonrepressive society would be less destructive and not more so. Marcuse argued that the death instinct was one

of the archaic powers whose identification was one of Freud's greatest insights. His point about this relationship was that capitalism had *allied* itself with the archaic death instinct. This weaker claim made the relation contingent and, at least in principle, possible to sever. This is precisely what Marcuse subsequently claimed was happening where he took the arrival of affluence to indicate that capitalism had managed to realign itself with Eros in the form of the drive to consume and enjoy.

In contrast to Marcuse's attempt at a strong politicization of the Todestriebe, Lacan's return to Freud was less dominated by explicit political commitment. It also questioned any simple equation of Todestriebe with the destructiveness of capitalism. In his seminar titled *The Ethics of Psychoanalysis*, Lacan draws upon Sophocles' *Antigone* with its depiction of the aftermath of the expulsion of Oedipus from Thebes. Lacan highlights the way in which the heroine of the play adopts a moral stance by embracing death rather than moral compromise. She will bury the corpse of her brother even though he is deemed an enemy of the city and this act will expose her to a sentence of death.

Antigone is sentenced to real death, but she also embraces a figurative death of the self which involves rejecting the Theban community that forms the very foundation of her existence. She subverts her own being and is, for Lacan, lodged *between two deaths*: social death and the final death that is associated with burial or (in Antigone's case) entombment. Lacan favors such subversion of the conventional role. But Antigone's subversion is a personal one. It is not subversion of a sort that could readily be taken over by a political movement. To opt for the latter would evade the need for figurative or social death and would simply involve a transfer of allegiance from one master to another.

Lacan's position is characteristically elusive and difficult to classify. It marks a further departure from the familiar Marxist critique of capitalism as peculiarly allied to the death instinct, although it allows that capitalism makes siding with or against the death instinct into a live issue. Little remains of Reich's clear-cut alignment of anticapitalism and Eros. A Reichian approach subsequently resurfaced in Deleuze and Guattari's *Anti-Oedipus* with the claim that capitalism generates the death instinct because it invests in destructive capability at the expense of the maintenance of life.

Popular Culture

Apart from its appropriation by social theorists and the therapeutic application of the Todestriebe by Klein, the idea of a death instinct has worked its way into popular culture. It has been featured as the theme and title of novels and is a background influence upon several films. *Basic Instinct* is sometimes suggested as an example of a film with suitably Freudian credentials. Aggression, self-destructiveness, and sexualized violence all figure prominently in this film.

Friends, Impact of Death of

In a postmodern era when friendship is often more highly prized than in previous generations, many individuals create a family of investment or a family of friends to enhance, supplement, or replace the family of origin. For others, kinship and friendships overlap: "My mother was my best friend" or "John was like a brother to me." Funeral ritual, estate inheritance law, and custom

still favor bloodline for grief recognition, ritual planning and participation, and social support. A friend, although emotionally closer to the deceased than some or all kin, is generally excluded from the inheriting and from making or challenging funeral rituals. Corporate bereavement leave policies rarely recognize grief for a friend. Consequently, some find their grief for a friend—or the intensity of the grief for a particular friend—discounted or disenfranchised.

Friendgrief is significant. Given an estimated 2.25 million deaths per year in the United States, and assuming a dozen friends are impacted per death, the grief of millions of friendgrievers is disenfranchised with dismissive responses like, "She was only a friend."

Individuals grieving for friends have been identified as survivor-friends, hidden grievers, forgotten grievers, and friendgrievers. Friendgrief is complicated for grievers who have not yet found a word or phrase to capture their loss. This entry first reviews the fluidness of definition and impreciseness of the use of the word *friend* and offers a brief discussion of the ways this friendgrief can be enfranchised. Finally, implications for clinical care and social policy modification are addressed.

Friend: The Concept

Historically, death rituals were a tribal experience in which family and friends grieved in tandem. Over the past century, funeral rituals have become primarily family-centered, with nonfamily relegated to the margin. But what does a particular griever mean when using friend in a lament such as "My friend died last week"? Friend is an umbrella word covering a wide variety of friendly relationships. One needs a qualifier to comprehend a griever's use of friend: best friend, old friend, longtime friend, girlfriend, childhood friend, close friend, casual friend, or true blue or longtime friend. The relationship may be so fluid that yesterday's best friend is today's close friend or ex-friend. Three common categories—casual friend, close friend, and best friend—are complemented by synonyms such as pal, confidante, best bud, buddy, mate, and compadre.

The absence of a straightforward definition for friend creates confusion. Dictionary definitions generally emphasize non-blood-related, nonmarried, and nonsexual relationships. Many, however, would challenge the exclusiveness of that definition—"but I consider my spouse to be my best friend."

Until recently, researchers were unaware of, or unconcerned for, the large population of grieving friends. Grief recognizes no boundaries of law or kinship and is a reality for those who friend and who have been friended. As the baby boomers die, large numbers of survivors will face grief over long-term friendships. Many will discover that the emotions stimulated by a friend's death can be as or more severe than grief for family members. Some friends' grief will be disenfranchised, or the intensity or duration discounted, even by co-friends or mutual friends.

Friendgrief is stressful for individuals who have few friends or who do not know how to make, maintain, or enhance friendships. Some individuals, particularly males, have few or no friends. Some grieve for past friendships that have ended or ended badly; grief can be heightened when friends were estranged. Thus, the death of a friend in a sparse friendship network challenges the griever, particularly when the spouse was the best friend or only friend. Many males acknowledge, "My wife is my best friend." The death of a wife is a dual loss. Ironically, the deceased may have been the friend to whom an individual would have turned for emotional comfort and support.

The loss of a friend is troublesome in the stereotypical masculine professions, such as the military, police, fire, and emergency service providers, in which friends die in traumatic incidents. The colleague, because of the shared potential of harm, becomes a buddy. The friend may be encouraged to disenfranchise public expression of grief to maintain unit cohesiveness. Some assume that outsiders to their profession cannot understand their particular grief.

Harold Ivan Smith has conceptualized that friendships function like orbiting planets around a magnet-friend; some orbits are tight; others illustrate friendship contacts that are less frequent but nevertheless valued. Friends may not have seen each other for some time but report, "We just take up where we left off." Some friends are friends through a shared friendship: Jan knows Ken because each is a friend of Susan. If Susan dies, Jan may or may not continue to be friends with Ken. Over time, one, or both, may delete the other from

their friendship roster. Some individuals have friendships through marriage or partnership. After a married friend's death, the foursome friendship cannot survive as a trio of friends; the deceased may have been the "glue" of the friendship. Some assume the promise, "We'll be there for you," to be a social coupon. Over time it becomes apparent that the promise-makers were more friends of the deceased than of the survivor.

After a death, friendships are reevaluated, reaffirmed, or reconstituted. Indeed, after a death, friends may actively solicit a commitment, "We've got to stay in touch" yet drift apart.

Within friend networks, subgroups of particular friends interact—whether college friends or war buddies that occasionally gather for reunions or workplace friends who go drinking after work. Thus, a memorial may be the first gathering of the deceased's extended friend network with conversation starters such as "And how did you know the deceased?"

Conceptual and Practitioner Perspectives of Friend

The grieving process may be hampered when a family's recognition of a friend of the deceased is at odds with others' perceptions. One family, following an adolescent's drug-related death, asked the funeral director to keep "those so-called friends of his" from attending the services. Nevertheless, these friends needed some ritual opportunity to confront the reality of their friend's death and their emotional reactions. Definitions of friendship shape expectations of support. In U.S. culture a friend must not complicate, overshadow, or undermine the family's recognition as chief mourner(s).

Generally, friends are expected to "be there" for the family. Friends offer—or may be expected to offer—condolence assistance through notifying other friends, offering advice if requested, providing transportation or lodging for out-of-town family members, sending flowers or donating to a designated charity, sending expressions of sympathy (cards, letters, or e-mails), preparing/donating food or providing meals, and attending rituals. Family grievers may assume that all promises of future assistance are collectable and may, after failure to meet expectations, reassess the friendship, "Some friend he turned out to be."

When family members are estranged and the deceased, while alive, had taken on friends as his or her "new" family, navigating the legal, emotional, and ritual impacts can be daunting. Friends who immerse themselves in assisting the family—acts that friends are expected to offer—may distract themselves from their own grief. Some may be tempted to "out-compassion" other friends. However, excessive "thereness" for the family, or for other friends, can lead to complicating one's own grief.

Friendgrief as a Disguised Sorrow

As a consequence of family dysfunction, some individuals create families of investment and invest emotional energy in, and receive support and nurture from, friendkin. The television series *Friends*, a popular television sitcom, portrayed a de facto family. Lesbians and gays establish, value, and maintain families of choice composed of friends, sometimes including ex-lovers.

Friendships are escrow relationships for times of stress. The childless elderly may first turn to friends for assistance. Thus, deaths in these invested friendkin are unrecognized, or underrecognized, particularly by the families, by the manufacturers of social expression, and by those who administer corporate bereavement policies. Managers and workplace colleagues may not recognize, appreciate, or comprehend the intensity of the grief following a friend's death.

Senior adults may experience an underrecognized bereavement overload due to the shrinking diminishment or blurring of their social support network. One elder captured this reality in this way: "A whole lot of people are leaving here. And each one takes another piece of me." Elders are saddened by the latest death of "yet another" friend's death; a memorial service may stir subtle wondering: Who will be next?

Gay and lesbians in the 1980s and 1990s were particularly battered by AIDS-related deaths. Some lost cadres of friends before pharmaceutical developments prolonged life. Grief for friends was heightened by the fear "I could be next" and the anxiety "Who will be there for me?" Grief was also complicated, particularly for closeted gays, by subsequent social stigma and calls for punitive quarantine. On the other hand, AIDS mobilized

and strengthened support services offered by friends and began to challenge hospital "family-only" visitation policies.

In some inner-city neighborhoods, adolescents repeatedly experience friendgrief resulting from violence, substance abuse, and gang behaviors. Some adolescents fear that their friends will not live to be their friends in adulthood.

Friendgrief may be complicated by individuals who want friends to "remember me as I was" and thus discourage visiting. Individuals may be denied good-bye experiences by a family's interpretation of hospital visitation policy. Consequently, friends may feel a particular need to express good-byes through attendance at memorial rituals.

The family/chief mourner may ignore or amend the deceased's wishes, oral or written, to limit ritual participation by friends or even to exclude certain friends from attending rituals by using the phrases "services will be private" or "family only" in newspaper obituaries or death notices. This decision may be further offensive when a family then permits certain friends to attend.

Implications for Clinicians

Personal experiences of friendship, death, and bereavement influence clinical practice. Clinicians must set aside personal understandings, shaped by their experienced friendships, to enfranchise a client's friendgrief. Just as a patient defines pain, the client defines friendship and the subsequent friendgrief.

The most meaningful friendships cannot be captured in intellectual terms but rather through stories. Narrating a friendship's highs and lows offers a means to witness the richness of a particular friendship and provides insight into the grief experience.

Clinicians must re-enfranchise grief experiences that were dismissed, discounted, or disenfranchised—particularly by deaths that confront one's sense of immortality, invulnerability, or assumptive worldview. This is particularly important for children, adolescents, and young adults. An individual may be the only friend in the orbit embracing this intensity of grief; continued engagement with the grief may isolate the griever from others in the friend network. Individuals may use chemical substances or unwise behaviors to "medicate" their sorrow.

Thorough grief for a friend needs to be honored in a "grief-lite" society. If the event is the first significant exposure to grief, the griever may not recognize his or her emotions as grief. By naming this grief, the clinician may help the friendgriever explore ways to maintain a continuing bond or to memorialize the friend. The clinician has the opportunity—in a culture that wants, even pressures, grievers to "move on"—to encourage the friend to "move into" the grief.

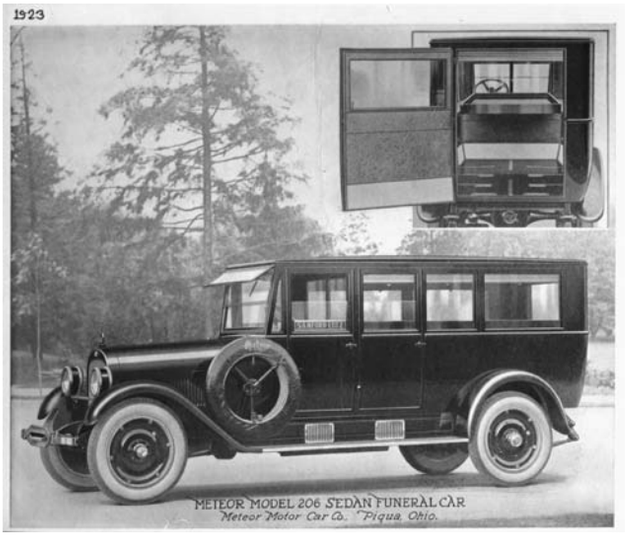
Funeral Conveyances

The first dedicated funeral vehicles are thought to be the sledges of ancient Egypt appearing in tomb art. Greek historian Diodorus Siculus described the richly decorated four-wheeled carriage that transported the golden coffin of Alexander the Great in 323 B.C.E. *Hearse*, the word used for contemporary funeral vehicles, originated from the rake or hirpex used by Roman farmers (also called a harrow in Saxon England or a hearse following the Norman invasion of 1066), which



Compared to the wood-intensive, carved-column hearses that descended visually from horse-drawn vehicles, steel-paneled limousine-style funeral coaches like this 1923 Meteor Model 206 offered a completely modern silhouette that complemented other cars in the funeral procession.

Three-way hearses, which first appeared in the late 1920s, employed a Y-shaped track that allowed a roller-covered casket table to emerge from either the side or the rear of the body. The system's curbside capabilities reduced loading height for the pallbearers and freed them from stepping into unpaved or muddy streets during the funeral service. This Henney-bodied 1937 Packard further enhanced convenience with an "Elecdraulic" power table.

The first purpose-designed flower cars appeared in the late 1930s to replace the open touring cars and phaetons that had previously ferried floral tributes in the funeral procession. Open well models were dubbed "Western-" or "Chicago-" style flower cars because livery services in the Windy City were among the first to use them, while "Eastern" style flower cars like this 1940 Meteor LaSalle had opening rear doors or tailgates that could admit a casket when the hydraulically inclined deck was in the horizontal position.

The significant growth in U.S. cremation rates has compelled coachbuilders to introduce optional urn carriers that allow the hearse to maintain a ceremonial role in a casket-less funeral. resembled the candelabra of Norman funeral services when it was inverted and held aloft. Placed on the coffin lid during the funeral procession, this candleholder gradually grew in size to accommodate new saints and holidays, and evolved into a wheeled vehicle by the 16th century.

Purpose-built funeral conveyances became common in the United States during the second quarter of the 19th century, when local churchyards were superseded by large landscaped cemeteries on the outskirts of cities and the undertaker transitioned from a carpenter or furniture maker who made coffins as a sideline to a full-service professional who hired vehicles. Their horse-drawn equipment underwent major design changes fairly infrequently, but one major change that occurred during the 1870s and 1880s saw the narrow-bodied, oval-glassed hearses that had dominated for the previous half century eclipsed by more ornate creations touting intricately carved columns, roof-mounted urns, and tasseled draperies for the casket compartment. Guided in its vehicle selections by newly available trade journals, the typical funeral firm might also operate a plain or sunburst-paneled service wagon for "first calls" at the railway station or the home of the deceased, a fleet of mourners' carriages, and a small, white hearse for the funerals of children.

With few exceptions, the funeral trade was among the last to employ horse-drawn vehicles in large numbers. Many cemeteries banned gasoline engines because of noise, soot, and smell, and electric vehicles lacked the range to take a casket to a city's outskirts. It was not until January 15, 1909, that America's first entirely horseless funeral procession was staged in Chicago, Illinois.

As the trade journals published accounts of motor cars entering funeral service across the nation, the long-established builders of horse-drawn hearses took notice. Crane & Breed, a Cincinnati, Ohio, company that had introduced America's first metallic burial cases in 1853, was the first to announce a commercially produced, gasoline-powered motor hearse in 1909. Though the driver's seat was open to the elements, the vehicle's novelty was emphasized with an unusual rooftop sculpture inspired by the tomb of the Roman general Scipio. James Cunningham, Son & Co. of Rochester, New York, a renowned carriage maker since 1838, quickly followed suit with a semi-closed auto hearse unveiled later that same year.

While an Ohio-built Great Eagle made headlines by completing the first transcontinental auto hearse trip between San Francisco and New York City in 1913, horse-drawn funeral vehicles continued to outsell motor-driven models by 8 to 1 as late as 1915. The first auto hearses cost $4,000 to $6,000 while horse-drawn could be purchased for around $1,500. However, the motor hearse was easier to handle and stop than a horse-drawn one, and could justify its higher purchase price by handling more funerals in a given time frame.

Even if fully enclosed driver's compartments had became common by the time the gasoline pump displaced the feed loft in the mid-1910s, early auto hearses maintained a strong, Victorian-style visual resemblance to horse-drawn vehicles, with their intricately carved columns and drapery panels, beveled glass windows, and brass or silver-plated carriage lamps that might measure 4 feet tall on the more expensive coaches.

Because the hearse had to be longer and heavier than a standard passenger car, most early motor hearse makers assembled their own chassis using mechanical components such as Continental engines, Borg Warner transmissions, Timken axles, Eaton gears, and Delco electrics. This remained standard practice until Cadillac, Buick, and Packard began offering factory-built, long-wheelbase "commercial" chassis during the 1930s, though coach builders typically added their own unique trim and badges to the hubcaps, grille, and bumpers.

By the mid-1920s, automobiles were fully accepted aspects of the funeral procession and metal replaced wood as the most popular body material. Further encouraged by the advent of "combination" coaches that could be used as part-time ambulances, morticians gravitated to "limousine-style" hearses that resembled other period autos with their sleeker silhouettes, plain steel exterior panels, and full-length side windows that were often used to display flower trays inside the casket compartment. With a second set of side doors, limousine styling also proved ideal for the late 1920s introduction of "three-way" hearses with a Y-shaped track for moving a roller-covered casket table out of the side or rear doors of the coach. This curbside servicing device reduced loading height into the era's tall vehicles and freed pallbearers from stepping into rural community streets that were typically unpaved or muddy.

Limousine styling also proved itself ideally suited to evolving construction methods that culminated in the Superior Body Co.'s 1938 debut of the first all-steel welded coachwork. Instead of using wood, the carved-style hearses revived during the 1930s often employed stamped steel or cast aluminum panels to simplify construction and save weight. Another body type that became popular during the 1930s was the purpose-built flower car, a pickup-style vehicle that succeeded the open phaetons that had previously ferried floral arrangements in the funeral procession. So-called Western- or "Chicago"-style flower cars added open flower wells, whereas "Eastern-style" flower cars added a corrosion-resistant stainless steel deck that can be hydraulically inclined to accommodate different-sized baskets or placed in a horizontal position to allow a casket to be loaded into the compartment underneath.

Because civilian car production was suspended during World War II, there was huge pent-up demand for funeral conveyances by 1945. It was at this time that the Landau, distinguished by a heavily padded leather, vinyl, or fabric roof covering with opaque quarter panels and S-shaped bows, became the most popular type of hearse. The considerable inflation in new car prices between the prewar and postwar periods also created opportunities for new coachbuilders that produced relatively inexpensive funeral vehicles based on sedan deliveries and the new steel-bodied station wagons.

Whereas the Eureka Co. stuck to wood-framed bodies until the 1957 model year, the introduction of light, durable, and corrosion-proof fiberglass allowed budget market builders to offer a wide variety of body styles without resorting to costly steel tooling, and it also encouraged more elaborate exterior styling. Many coachbuilders eagerly emulated Detroit in their adoption of thinner window frames, wraparound windshields, and two- or even three-tone paint jobs, on top of which Superior offered a pillarless hardtop Beau Monde hearse from 1955 to 1956, and Miller-Meteor's 1956–1958 lineup featured a Crestwood model touting simulated "Mahogatrim" or "Walnutrim" paneling. By the early 1960s, hearse–ambulance combinations reached the apex of versatility with detachable roof beacons, landau panels secured over the rear quarter windows using slots or thumbscrews, and quickly reconfigured interiors featuring folding attendant seats and reversible casket rollers.

During the 1970s, ambulance customers switched to more-spacious van- and truck-based units, and General Motors downsized Cadillac's Commercial Chassis from a 157.5- to a 144.3-inch wheelbase. It was during this period that the annual output of Cadillac-based professional vehicles fell from 2,506 units in 1970 to 864 units in 1979, leading the three leading Ohio coach builders (Miller-Meteor, Superior, and S&S) to go out of business, merge, or reorganize on a smaller scale. After Cadillac introduced an even smaller front-wheel drive hearse platform in 1985, the rear-drive Lincoln Town Car gained a foothold with funeral directors though its dominance of the booming stretch limousine market. Aware that limousines and hearses were highly visibile, Lincoln and Cadillac established the Qualified Vehicle Modifier and Cadillac Master Coachbuilder certification programs to ensure these vehicles met or exceeded their own design standards and remained compliant with federal safety rules.

The vehicles funeral directors used for "first calls," flower transport, and other supporting roles became more diverse in the 1980s and 1990s. Suitable substitutes included Chevrolet and GMC Suburban sport-utilities and the spacious front-wheel-drive minivans pioneered by Chrysler. A number of coachbuilders equip these vehicles for funeral service by adding casket roller racks, plastic flower trays, and removable landau panels that can be slid off the quarter windows for an extra-discreet pickup at a private home or retirement village. Compared to traditional hearses, such conversions can be built from a base vehicle sold through a dealer and, if necessary at a later date, the modifications are almost always reversible.

During the early 21st century the significant growth in U.S. cremation rates has led coach builders to offer optional urn carriers, thereby ensuring the hearse will maintain its traditional ceremonial role in a casketless service. Antique hearses have also proven increasingly popular for the funerals of old car enthusiasts and auto dealers. Horse-drawn hearses are making a comeback among farmers, historians, environmentalists, or those who yearn for simpler days gone by.

Funeral Director

The funeral director is the professional in charge of the body handling and the organization of funerals. The tasks of the funeral director include the removal and care of the body, the dressing and placement of the body in the coffin, the supervising of the funeral ceremony, and the transportation of the body. This role involves coordinating a network of religious, medical, and community actors.

The history of the profession is characterized by a process of professionalization and commercialization, with funeral directors seeking to attract clients by devising and offering an ever wider range of services. As well as taking care of the preparation of the body of the deceased and arranging the funeral ritual, funeral directors now provide other kinds of support, not only to the family of the deceased (e.g., bereavement counseling) but also to the future deceased (e.g., through funeral planning), for those who wish to finance and arrange their own funeral in advance.

History

The origins of the modern funeral director can be traced back to the *libitinarius* in ancient Rome. He performed a number of functions, including embalming, providing professional mourners and mourning clothes, and organizing the funeral procession. Although the influence of these practices can be observed in the practices of 20th-century funeral directors in Western societies (particularly regarding the pomp and ceremony), undertaking as a profession goes back no further than the 19th century. Previously handling the dead was not a matter for specialists. When someone died, various members of the community would be mobilized: The livery stable keeper would provide the hearse and the funeral carriages, the local carpenter or the cabinetmaker would make the coffin, and the sexton would toll the church bell and dig the grave. Immediate and extended family, as well as neighbors of the deceased, would undertake certain tasks such as washing and dressing of the body, ordering the coffin, and finally carrying the coffin from the home of the deceased to the church and then, from there, to the cemetery.

Over time, businesses specializing in providing funeral services and supplies began to appear. The funeral director became no longer a mere supplier of equipment—coffins, hearse, pallbearers—but rather a professional playing a useful role in society, an entrepreneur who offered, for a charge, a wide range of services: washing and dressing of the deceased, casketing, transportation of the coffin, as well as provision of all the paraphernalia of mourning. The increasing control of funeral directors was a consequence of both the weakening of community ties and the decline in the influence of the Church, unable to maintain its authority over every aspect of the funeral rites. Moreover, the shifting of the location of the funeral to specialized premises further increased the funeral director's control over proceedings. As homes got smaller, the laying out of the body in the house of the deceased became impractical and more commonly took place in the funeral home, where there was sufficient room for families to congregate. Likewise, embalming, developed in the United States during the Civil War and involving increasingly sophisticated techniques and equipment, gradually moved from private homes to adapted funeral homes.

The professionalization of funeral directing was an answer to the new needs of not only the bereaved but also the funeral directors themselves. Significantly, it was at the end of the 19th century that these professionals started to refer to themselves as "funeral directors" rather than "undertakers," suggesting their growing responsibility in directing the performance of the funeral and in the handling of both the dead body and the funeral ceremony.

Throughout the 20th century, urbanization, the weakening of community ties, the rise of the nuclear family, and the medicalization of old age all contributed to the growing importance of the role of the funeral director. Nevertheless, from the beginning of the century, the wealthy began to reject pomp in favor of simpler ceremonies, and funeral directors suffered the competition from part-time workers. Professionalizing the industry was necessary. Professional associations emerged then, and the sphere of intervention of funeral directors progressively expanded. Today the profession is going through a period of restructuring, with concentration being a dominant trend. Family businesses that emphasize their long-established presence in the community and their personalized relations with their clientele are threatened by the growth of funeral chains.

A Widening Sphere of Operation

The range of services offered by funeral directors has significantly widened. They are now in charge not only of the body—from its removal to its burial or cremation—but also of the organization of the funeral. To satisfy the desire of the family to personalize the ceremony, a wide variety of services and articles are offered, allowing clients to freely choose their own individualized à la carte package. Among the expanding services are embalming, whose purpose is to make the corpse look as lifelike as possible and delay its decomposition. The arguments given by funeral directors in favor of theses treatment have evolved; whereas reasons of public health often used to be mentioned, nowadays funeral directors rely on aesthetic and psychological considerations, quoting bereavement experts who stress the importance of viewing in the grieving process. The treatments administered result in the "beautification" and "humanization" of the body, supposedly enabling the bereaved to keep a dignified image of the deceased. As the viewing has become more common, particularly in the United States, the use of techniques to treat the body has become increasingly a matter of routine. In charge of the preparation of the body, funeral directors gain greater control over the whole after-death process and develop technical, but also relational and symbolic skills; their expertise in the handling of both the deceased and the bereaved is claimed as a sign of professionalism.

Their role also expanded to the ritual sphere. It is increasingly common for funeral directors to be in charge of the funeral ritual, especially when dealing with a cremation or a civil ceremony. They are led to perform a "ritual bricolage," conducting simple ceremonies based on emotion, authenticity, and singularity. As a result of greater competition and the emergence of a profession associated with embalming, funeral directors have been once again forced to redefine their field of expertise. Postdeath services to the family of the deceased are multiplying and may include transporting the bereaved to the funeral and catering at the funeral home; other services may be performed over a long period of time (e.g., upkeep of the grave). Yet the accent is now put on counseling, including both grief counseling and taking care of various administrative procedures.

Finally, funeral directors are increasingly turning their attention to the deceased of the future. This trend is evidenced by the growing popularity of funeral planning, which involves prior financing and organizing of one's own funeral, with a view to both minimizing the inconvenience caused to the family and to ensuring that one's wishes are respected. These pre-arrangements enable funeral directors to "capture" clients in advance and to exercise their symbolic authority by ensuring that the services provided are meaningful for both the clients and, in the future, their relatives. The funeral director usually promotes authentic, personalized ceremonies, in which those people close to the deceased do not feel excluded and do not feel like mere spectators.

Thus, innovations introduced by funeral directors are rationalized as being in the interests of the client. In taking care of body-handling tasks, they relieve society of the responsibility for doing the "dirty work." The embalming and the viewing are presented as being beneficial for the bereaved; the removal of the body of the deceased to the funeral home relieves them of its presence at home; more generally, having an expert manage the whole process is, in many ways, advantageous. Finally, thanks to funeral planning, the family of the deceased is spared the responsibility for paying for and organizing the funeral. A constantly renewed merchandising strategy is, thus, at work.

The more prominent role played by funeral directors in funeral rituals, together with the growing demand for civil ceremonies, creates a relative competition, or at least a delicate collaboration, between funeral directors and the clergy. As the field of intervention of funeral directors has widened, the Church is concerned that its role played in funeral rituals may be threatened by the funeral industry. For those who want to have a funeral ceremony which, though not religious, nevertheless retains some elements of religious symbolism, the funeral director has come to embody a new kind of symbolic authority. Indeed, civil ceremonies conducted by a funeral director borrow some of the terminology and symbolism of Christianity. Indissociable from the sphere of the sacred, the funeral business has to commercialize its services in such a way as to reconcile the demands of the market economy with those of the economy of symbolic goods.

Expectations and Criticisms

In dealings between the funeral director and the bereaved, an element of uncertainty can arise. This is less likely to concern the quality of funeral equipment, which varies little, than the quality of the service provided, which is expected to encompass the performance of their tasks (punctuality, conscientiousness, reliability), their attitude (discretion, respect), and their appearance (dress, cleanliness). Human qualities and psychological balance are required. Funeral directors are expected to be good listeners as well as being empathetic and tactful. Confronted with distressing situations and with the hostility of the bereaved, who find themselves in a position where they have no option but to purchase funeral services, they may suffer from stress and burnout. As a reaction, funeral directors develop defense strategies in order to depersonalize the deceased, such as the use of slang and crude language—which is in sharp contrast to the euphemistic terminology used in the presence of mourners ("loved one" for the body of the deceased, for example). Funeral directors face a double constraint: They must show compassion toward the bereaved and win their trust in a critical situation while keeping sufficient distance to operate professionally.

Since the 1960s, funeral directors have been subject to a certain amount of criticism. Throughout the media, as well as in several bestsellers such as *The American Way of Death* by Jessica Mitford, funeral directors tend to be presented in a negative light, often being portrayed as greedy and cynical individuals who engage in fraudulent and morally reprehensible practices. They are accused of encouraging the bereaved to overspend and taking advantage of the ignorance and vulnerability of clients by selling them services unwanted, but misleadingly said to be required by the law. Already disoriented, the bereaved indeed have no way of knowing whether they are being overcharged for the services provided and are compelled to make a quick decision. Funeral directors are also criticized for their lack of transparency concerning their rates and, more generally, for making a business out of death. Organizations such as the natural death movement in Great Britain are highly critical of the way funeral directors have professionalized and alienated death, arguing that the bereaved are no longer active participants in funeral rituals and ignore the alternatives to commercialized funeral services (DIY [do-it-yourself] funerals, green burials).

To face their stigmatization and challenge the stereotypes associated with their work, funeral directors attempt to stress their professionalism and human qualities. By using various communication strategies and involving themselves in local life, they seek to establish their professional ethics, respectability, and role in society. Their stated objective is to contribute to giving meaning to death by supervising memorable, moving, and meaningful ceremonies, without substituting themselves for the religious actors. Funeral directors claim to guarantee public health, provide a public service, and treat bereaved families with the utmost respect. They also take pains to have the funeral home decorated in such a way as to create a suitably sober atmosphere, devoid of conspicuous signs of economic trade.

Consequently, despite the fact that, by managing the body-handling process, funeral directors perform a valuable role in society, their social status is low. Professionally, they feel unappreciated, sometimes even socially ashamed. The poor public esteem may be explained first by the fact that families know little of what the work of funeral directors actually entails, and second because funeral directors are reluctant to communicate

about body-handling. They would rather emphasize their responsibility in the smooth running of funeral ceremonies or their counseling of the bereaved. Gratification comes from directing "successful" funerals, from expressions of gratitude of mourners, or from the feeling of having a strong social utility. Nevertheless, the professionalization of funeral services has not led to funeral directors enjoying greater social recognition. On the contrary, the role played by funeral professionals has never been so important, but their public image has deteriorated.

Funeral Home

The funeral home is a business site where the dead are prepared for cremation or burial. It also serves as a location for friends and family members of the deceased to gather for funerary rites. These funerary rites are planned in conjunction with customers who were either intimately connected with the deceased or are legal executors of the deceased's estate. This entry describes the emergence of funeral homes in the 20th century, and the cultural and structural factors that have caused a shift in the organization and provision of services by funeral homes.

History

Throughout most of the 20th century, the postmortem processing and disposal of the dead was articulated in and through funeral homes. This was not the case prior to the turn of the 20th century, when most funerals revolved around the family home and sometimes the church. Up to that point, the ritualized burial of the dead relied on a host of different individuals in different occupations. Wheelwrights who built and repaired wheels for carriages also transported the dead body from the home, to the church, and to the graveyard. Cabinetmakers constructed coffins. Nurses, midwives, and other ancillary health workers cared for the body by cleaning it, laying it out, and, when necessary, keeping it cool. And members of the clergy oversaw the sacralized portion of the rituals. Cremation of bodies was relatively rare until the 1960s.

Emergence of Modern Funeral Homes

A number of factors contributed to the development of the modern funeral home. Arterial embalming for the purpose of memorialization was introduced to the American public during the Civil War. The display of well-preserved corpses, especially of notable figures like Lincoln, helped popularize the practice, and by the 1880s embalming schools and a major trade association, the National Funeral Directors Association, had emerged. Even then, "embalming surgeons" performed their craft with the aid of portable machines that had a

manual pump, and embalming was carried out in the homes of the deceased.

The concentration of populations in cities contributed to the need for specialized facilities into the early part of the 20th century. Urbanization made it increasingly difficult to transport caskets and equipment while negotiating congested thoroughfares, walk-up flats, and smaller city spaces. The introduction of wiring and indoor plumbing made possible the use of electric embalming machines. This development further specialized funeral work and created a need for delimited spaces in which to conduct this work. Furthermore, the medicalization of dying and death expanded beyond the reach of hospitals and into the lives of citizens. This served to rationalize the dying process and consign the dying and the dead to institutions, rather than allowing them to remain in the home. Aligned to some degree with the discipline of medicine, embalming became an increasingly legitimate task and the embalmer was perceived as a skilled technician.

As a result of these developments, funeral "parlors" emerged in the 1880s, and spread across the country over the next 30 years. While funeral homes emerged as specialized sites to conduct the tasks of embalming and demi-surgery (cosmetizing and restoration), it was only in the middle of the 20th century when they became common gathering places for family members to conduct their wakes or visitations and serve as chapels in which to hold funeral services. Funeral home workers began to assume more control over funerary rites in addition to regulating what occurred to a body after death.

A few basic features comprise the physical makeup of a funeral home. The prototypical configuration includes a chapel, one or more visitation rooms, a "prep" room for embalming, a display room for products such as caskets and guest registries, an arrangements room to meet with customers, and a business office. And while in the past most crematories were located at cemeteries or mortuaries on cemetery grounds, about half of all funeral homes currently have a crematory and most of these have a viewing area available to the bereaved. Today, many funeral homes also outsource their embalming to firms that specialize in such tasks. Other funeral homes merely maintain a presence in an office, thereby serving as an arrangements-only firm that connects the customer with third-party vendors.

Regulation of the Funeral Industry

With the exception of the Funeral Rule, which the U.S. Federal Trade Commission instituted in 1984 requiring firms to provide itemized price lists along with other important information for the protection of consumers, funeral homes are regulated by individual states. About half of all states have special licensing for crematory operators but typically do not require secondary education. Many states have separate licensing criteria for funeral directors and embalmers, requiring that funeral directors perform an apprenticeship under a licensed funeral director. Embalmers are required to attend an accredited mortuary services program and earn either a degree or obtain a specified number of credit hours to obtain a license. About half of the U.S. states have a dual licensure system, and most states require that embalmers have at least a 2-year associate's degree from an American Board of Funeral Service Education–accredited program.

Cultural Shifts Affecting Funeral Homes

In the 1990s funeral homes began to change dramatically as a result of a confluence of factors. Secularization, the growing pluralism among religious persons, and a highly mobile population all contributed to more ecumenical and nonreligious funerals. In addition, consumerism became prevalent. Due to a number of economic and marketing factors, a large portion of the population could participate in the mass-production funeral market. Consumers began to expect choice when it came to their purchases, which necessitated a change in the ways funeral companies conducted their business in funeral homes. Furthermore, baby boomers, who were beginning to bury or cremate their parents, are a highly individualistic generation. Consequentially, personalization became a dominant trend in the funeral industry in the 1990s, and funeral homes changed in order to make customizable funeral services available. In the past, clergy and funeral directors led much of the service but increasingly the attendees were being included.

Also during the 1990s, funeral corporations that had borrowed heavily to finance a heightened

period of mergers and acquisitions began to encounter economic challenges. The growing debt, paired with a declining death rate for North Americans, meant that new means for generating revenue had to be discovered. These structural changes, in tandem with the aforementioned cultural changes, affected the appearance of funeral homes. To accommodate customers who wanted to personalize their funerals with multiple speakers and make their funerals more informal, chapels and visitation rooms were outfitted with multimedia systems to play prerecorded music or record services on DVDs.

In an effort to both bolster revenues and attract baby boomers, many funeral homes began to make their spaces appear less distinctive through the removal of wallpaper, furnishings, and architectural elements in order to distance themselves from conventional funeral home appearances. The transition toward making both the interiors and exteriors of funeral homes less funereal and morbid began taking place after 2000. The interiors of such funeral homes often resemble contemporary office décor. Instead of caskets in a display room, many firms only display corner pieces or catalogues. Other funeral homes eliminate the word *funeral* from the signage or advertise their ability to function not only as funeral homes but as facilities for multiple forms of events or meetings. Many funeral homes remove iconography that suggest adherence to one cultural or religious tradition to appeal to a multiethnic and religiously diverse clientele.

With the rise in the cremation rate, which is one third and rising, there is also a subsequent rise in the number of customers who want to forgo funeral services altogether, instead opting for direct cremation, which currently occurs in approximately two thirds of all cremation cases.

Corporatization

The largest funeral corporations control about 20% of the funeral homes in the United States. Their increased presence, especially since the 1990s, represents an important shift in the ways funeral homes are operated. From the corporate side, conditions were ripe for acquisitions because of overall market increases in venture capital and perceived reductions in risk. At the same time, many owner-operated firms had no willing successors, and attrition was on the rise. Such consolidation leveled out by the early 2000s.

Critics of corporatization often charge that corporations overprice their products and overstandardize services. Some critics also worry about hostile takeovers of "mom and pop" firms. When a firm sells out, corporations typically retain the original owner to remain on site, at least temporarily, to oversee the transition and ensure continuity within the community with regard to "good will" value. However, the products and services typically change in these funeral homes.

Many African Americans are concerned over the corporatization of the funeral industry. Funeral homes were among the first businesses blacks could own in the United States, and these firms were deeply embedded in their communities. Black funerals continue to be less affected by secularization than white funerals and tend to be less reserved. African American–owned funeral homes still rely on advertising in church bulletins (in addition to word-of-mouth), attesting to the ongoing ties to religious traditions. Black-owned funeral homes provide embalming services and assistance with arrangements, while the funeral services are typically held in the church.

Clustering Practices

Clustering is a practice that allows several funeral homes in the same market to share resources and reduce expenditures. One funeral home acts as a hub, which can serve as a warehouse for goods like caskets, vehicles, and other necessary equipment. It can also house staff that need not maintain a full-time presence at satellite funeral homes. By centralizing embalming duties to the "hub," the costs of space, equipment, staffing requirements, and upkeep for OSHA (Occupational Safety and Health Administration) standards are reduced. While this integrated structure originated in corporations, increasing numbers of independently owned homes with multiple funeral homes are turning to this approach.

Clustering also results in a degree of specialization, as certain tasks are only conducted at particular firms. This represents a shift from the past in that funeral home staff members no longer engage in a wide variety of tasks; rather, specific tasks are

conducted on a full-time basis. Thus persons designated as funeral counselors perform no embalming and may not oversee a funeral service, and many firms employ full-time, pre-need salespersons who earn commissions for their work. Removal of funeral directors from traditional social relations within their community means that staff can be transferred and relocated, thus representing a shift from when funeral directors were involved in civic groups and other community organizational activities.

Reminiscent of a period when funeral homes were, in fact, actual homes in which funeral directors resided, a few independent family-owned funeral homes staff their facilities around the clock. However, services are increasingly used to take calls after hours. Many decry this transition if only because any delay in beginning the embalming process requires an increased amount of fluids to reverse the effects of decay that begin at the time of death.

Finally, throughout most of the history of the funeral industry, funeral direction and embalming has been a male-dominated profession. However, currently over half of mortuary college graduates are women. Although viewed as a change by some analysts, in the 1800s many of the workers involved in undertaking tasks were women until male tradesmen and embalming surgeons became more prevalent in the preburial tasks. Although some may attribute this increase in the hiring of women to be reflective of job equity factors, critics argue that the shift is attributed to the salience of stereotypical associations with women as more capable of the kind of emotional labor and service work demanded in funeral homes.

Funeral Industry

The funeral industry comprises professional establishments associated with the provision of funeral ceremonies, held in connection with the wake, burial, cremation, and memorial rites of the dead. This definition includes those related activities required to facilitate the funeral ceremony, including, but not limited to, the transportation of the deceased, the registration of death, makeup of the corpse, embalming, preparation for the wake, the production of obituaries, and equipping the bereaved with commodities required in the funeral ceremony. As such, funeral homes, funeral parlors, funeral companies, corporations, conglomerates, and crematories are included under the umbrella term *funeral industry*. Funeral directors, funeral conductors, cremators, embalmers, and the staff who work in these organizations are the professionals who comprise the funeral industry.

The phenomenon of the funeral industry is neither universal nor homogenous across cultures. The form of the funeral industry depends on the management and control of the dead and the bereaved during the death ritual, within cultural variance. Furthermore, the funeral industry incorporates both commercial and nonprofit organizations, as long as these establishments and those who work in them are specialized in the treatment of the corpse or assist the bereaved with prefuneral, funeral, and/or postfuneral ceremonies. The following discussion of the funeral industry serves to illustrate its past, present, and future through an examination of its emergence, development, and outlook, with reference to some common criticisms.

Emergence of the Funeral Industry

The funeral industry is a product of modernization, urbanization, rationalization, and specialization. In industrialized societies such as Europe, North America, and Japan during the 19th century, the increasing urban population led to high urban death rates. The problem of disposal of this large number of corpses was commonly addressed by the development and promotion of cemeteries outside of cities, reusing cemetery spaces, and by promoting cremation. In all cases, swift disposal of the dead became important for both health and social-cultural reasons. The development of the funeral industry occurred in parallel with the increased importance given to maintaining public health by safely disposing corpses.

A second factor in the emergence of the funeral industry is the attenuation of community ties. Prior to industrialization and urbanization, death was managed by family and community members. When death occurred, the family took care of their loved ones and performed the ritual traditions. The community helped in transporting, digging, and burying or cremating the deceased, as well as providing a coffin and other paraphernalia. Local priests were called upon for religious services, assisted by community members. Communities owned local cemeteries or graves where the dead reposed. Death and funeral performances were an essential communal responsibility that maintained communal solidarity. However, as urbanization progressed, such communal ties weakened as the youth moved to the cities and left their elders behind. As a result, much of the community funeral knowledge was lost.

The specialization of work and the control of knowledge by the funeral industry were outcomes of this attenuation of communal ties. Prior to the emergence of the funeral industry, there were undertakers in urban areas who assisted the bereaved in various tasks such as providing a coffin, digging the grave, and providing the paraphernalia and upholstery for funeral rituals. These were not funeral specialists but nurses, craftsmen, carpenters, cabinet makers, construction workers, liverymen, or carriers, who occasionally extended their routine work skills to a part of the death ritual. The transformation from undertaking/undertaker to a funeral industry can be marked by their full transition to providing specialized services catering for the dead and bereaved, where community members could not provide the required services or where family members willingly relinquished their responsibilities. Major specialized tasks offered by the funeral industry were prefuneral and funeral services such as embalming, applying makeup and encoffining the corpse, registering the death, preparing for the wake, writing obituaries, equipping the bereaved with commodities for funerals, transporting the deceased and family, and providing postfuneral memorial services such as cremation or burial.

Various Forms of Funeral Industry

Tony Walters examined the funeral industry from a global perspective and found that specialized funeral services are performed by commercial, municipal, or religious organizations, or any hybrid of these, depending on their part of the world. In North America, commercial funeral parlors take care of the corpse and performing services at the prefuneral and the funeral. Cremation, as a postfuneral service, is mainly provided by commercial organizations, while cemeteries are managed by community and religious organizations as well as commercial organizations. In Europe and especially France, Germany, and Italy, prefuneral services are provided by enterprises owned by local government, while municipality-owned cemeteries have replaced most of the church cemeteries. Among Jewish and Muslim groups around the world, funerals are prepared and run by local religious groups, and the dead are buried in cemeteries either owned by the religious group or in a religious section of a municipality-owned cemetery, or in a privately owned cemetery. In most societies, the funeral industry is not a singular entity but, rather, a hybrid. It can comprise several organizations, as in the United Kingdom or Japan. In the United Kingdom, the funeral director takes charge of the prefuneral and funeral services, while the corpse is taken to the cemetery, which is owned and operated by the Church. In Japan, the funeral companies take charge of the deceased and the bereaved, from picking up the deceased at the hospital, through the cremation, to the memorial ceremonies. The remains of the deceased are kept in graves or ossuaries in either Buddhist temples or

private cemeteries. In recent years, new practices such as the scattering of ashes have become popular in Japan due to the lack of grave space, the high cost of graves and ossuaries, and more importantly, the lack of inheritors who would worship the grave. Funeral companies began to tailor services for those who want the deceased's remains scattered at sea by arranging a funeral conductor to execute the ritual process and arrange a hired boat.

Hence, the funeral industry emerged from the division of labor, specialization, and the control of funeral knowledge where local community ties attenuated during rapid modernization. Whether organized as a private, municipal, or religious entity, and as a result of urban social changes, the funeral industry took on the necessary task of caring for the deceased and assisting the bereaved through the ceremonial process.

Development of the Funeral Industry

As the funeral industry developed, it came to acquire three defining characteristics: (1) specialization in handling the corpse, (2) standardization of funerals, and (3) offering comprehensive services to the bereaved.

Specialization in Handling the Corpse

One of the most important tasks of funeral staff or directors is the ability to handle the corpse. Firstly, this involves picking up the deceased from a residential house, hospital, nursing home, accident site, or police station. A professional demeanor, being respectful and courteous to the corpse regardless of its condition, is essential. Handling of the corpse also includes cleansing, covering up damages, dressing, makeup, and encoffining the deceased. In cultures where they do not embalm, it is the responsibility of the funeral industry to preserve the deceased (dry ice, etc.) until the end of the funeral ceremony. Introduced into the United States during the Civil War, embalming has penetrated both the U.S. and the U.K. markets today. The development of the funeral industry and the commercialization of death went hand-in-hand with the specialization of embalming. Embalming signifies technology and scientific skills and the authority of its profession. Not only did embalming give expertise to funeral directors, the scientific knowledge they acquired also guaranteed proceeds to the funeral industry. Moreover, the repetitive performance of embalming by the funeral industry brought a proliferation of its custom, which in turn legitimized embalming as part of the American way of death. The institutionalizing of embalming cemented the final viewing of the deceased as part of the funerary tradition.

Not all cultures or funeral industries perform embalming. It was brought to Japan by U.S. funeral directors and morticians in the 1990s, and larger funeral corporations are gradually increasing its application. However, in Japanese funerals, embalming is still performed less frequently than is the bathing ceremony. The bathing ceremony is a reinvention of the ritual that once took place in community funerals. The bathing ceremony does not use technology; it simply washes the deceased in a ceremonial manner. In Japan it is not scientific knowledge but traditional knowledge combined with professional experience in handling corpses that provides legitimacy to the funeral industry. Irrespective of the processes used, it is the culturally dignified treatment of the dead that legitimizes the funeral industry to provide funerals.

Standardization of Funerals

The standardization of funerals takes place in the context of changing social processes; that is, along with similar transformations in other industries, the funeral industry is transforming funerals into an efficient structure, a bureaucratic procedure, and a predictable operation. Over time, the funeral industry obtained funerary and managerial knowledge that allowed it to process a funeral in an efficient manner. Mastering the sequence of the wake and funeral, the funeral industry ushers the bereaved from one stage to another smoothly and with a minimum of interruptions—from transportation of the deceased, getting the death certificate, embalming, preparing for viewing, inviting priests, arranging the burial or cremation through to the postfuneral services. Each stage of the funerary performances is predictable in terms of cost and calculable, allowing the bereaved to select the casket, funeral hall, funeral altar, burial, or cremation with the information supplied by the funeral industry. The funerals are clearly structured, and

each stage of the funeral performance is professionally operated and managed as described by the funeral industry. The number of funerals led by the funeral industry in each culture has produced a standardization of funerals and funerary performances. Thus, the way of death in each culture has become a bureaucratic, rational, and professionally orchestrated procedure rather than an ad hoc process.

Comprehensive Services

The funeral industry offers comprehensive services to the bereaved's family and often acts as a one-stop shop for funerals. The funeral directors guide the bereaved from the deceased's death all the way until the end of the funeral. They transport the deceased, embalm and/or cleanse the deceased in their mortuary, help the bereaved get the death certificate (and possibly cremation permission) from the government or municipality, prepare acknowledgment or notification cards for the funeral, and provide caskets, coffins, urns, or other necessary paraphernalia. Their control of the merchandizing, on display at a funeral home or on the Internet, allows the funeral industry personnel to sell the funeral while in the family's home. This merchandizing, in addition to the handling of the corpse covered earlier, enables the funeral industry to be all-encompassing.

In summary, specialization in handling of the corpse, standardization of funerals, and comprehensive services can be seen as the bureaucratization of death by the funeral industry. Handling of the deceased from prefuneral to the end of the funeral allows the funeral industry to control the perception of death and the funeral process.

Critiques and Defense of Funeral Industry

The public and media have often been critical of the commercialism of the funeral industry, viewing it as dismal trade. One of the strongest criticisms came from Jessica Mitford's 1963 book, *The American Way of Death,* in which she illustrated how the funeral industry manipulated vulnerable customers into purchasing expensive caskets, coffins, and other paraphernalia. She pointed out that embalming in America is a tradition invented by the funeral industry for its profit, and thus it is unethical. The Japanese media has also portrayed the funeral industry as a lucrative business. One example is seen in how Japanese Buddhist priests are regarded. After the 1970s economic boom, the Japanese public and media began to describe Buddhist priests and their temples as total profit-making priests (*bōzu-marumōke*) because of the high price of their funeral services which, to a layman's view, only required the slight effort of chanting Buddhist scripts and providing a posthumous name to the deceased. Such criticism, however, is appropriate only after considering the particular context of cultural, social, psychological, religious, and afterlife values, which in turn illustrate that the handling of death by the funeral industry is not all about commercialization.

One of the reasons for the negative perception of the funeral industry stems from its obligation to provide services during the period when people are vulnerable, in shock, or emotionally unstable. Purchasing decisions made before the funeral can easily be regretted afterward, in which case the funeral industry gets the blame. While some funeral directors may manipulate the vulnerable bereaved to sell more and expensive services, there are many downsides to such excessive profit making. The funeral industry, like any other, needs a good relationship with the clientele and communities they serve to get repeat customers, referrals, and recommendations.

Vanderlyn R. Pine and Derek L. Philips's 1970 study of a U.S. college town with a population of approximately 7,000 showed that funeral costs were higher for deceased who were older or from the middle class than for those who were younger or of lower or higher social classes. These different funeral costs reveal what is important to the bereaved. Hence, the correct amount of funeral expenditure depends on what is considered a decent funeral by the individuals involved, which in turn, depends upon who the deceased was—including the bereaved's social status, religious background, and culture—and when the funeral took place.

Outlook for the Funeral Industry

The current trend within the funeral industry is to personalize funerals within the deceased's cultural homogeneity. In recent years, the commercial

funeral industry has changed from small, family-owned funeral homes to larger, funeral corporations or multinational conglomerates. Irrespective of the organization type, the survival of the funeral industry depends on its ability to adapt to consumer needs. In many cultures, consumers demand a wide variety of funeral types; people want to personalize their funerals. In the United States, death wishes show an increasing rejection of embalming. Instead, the bereaved may want their loved one's ashes made into diamonds or sent to the moon. A number of Japanese housewives wish to be buried, not in their husband's ancestral grave, but in a collective women's grave or to have their ashes scattered under a tree. The funeral industry is an adopter of cultural and social changes, and at the same time, a producer of the new services and products consumers demand. However, the funeral industry does not craft a fusion of global funeral culture. Although the funeral industry may export a ceremonial performance (e.g., exporting embalming from the United States to the United Kingdom, Australia, Singapore, Japan, and elsewhere), and the techniques used are similar across countries, their interpretation and its value in the ceremony are unique to each culture. Hence, the funeral industry will continue to conform to social changes and consumer needs, while creating homogeneity in the funerary culture they serve.

Funeral Industry, Unethical Practices

Family members are particularly vulnerable at the time of the death of a loved one to feelings of guilt and despair. This vulnerability can lead to magnifying the processes of rites and rituals involved in funerary practices. Individuals who are involved in the for-profit funeral industry know these psychological phenomena and find it easy to exploit the vulnerable in order to profit handsomely from providing funerary services.

Widespread ethical problems in the funeral industry were first highlighted by the 1963 muckraking exposé, *The American Way of Death*, written by Jessica Mitford with her husband, Robert Treuhaft. Mitford's book exposed a range of practices seemingly designed to maximize the cost of funerals. They ranged from outright deceptions, such as telling consumers that embalming was a legal requirement, to providing underwear and universal "fitafut" shoes, even when only the upper part of the corpse was to be displayed in a split lid casket. Mitford's graphic description of embalming in particular enraged readers of the book, which quickly became a best seller.

The public outcry that followed its publication prompted the U.S. Congress to hold hearings on the funeral industry. Eventually the U.S. Federal Trade Commission (FTC) issued its Funeral Rule in 1984, which sought to end the secrecy surrounding funeral costs and the practice of forcing all consumers to pay for all services, whether wanted or not. The rule requires that consumers be given complete and itemized cost information for specific services to be provided.

Although the Funeral Rule led to more accurate and easily understood information, the funeral industry adopted marketing practices designed to represent the funeral home personnel as friendly and supportive of grieving families, appealing to a

combination of guilt and gratitude to encourage decisions for more expensive options. The revised practices of a revived funeral industry prompted Mitford and Truhaft to write a second scathing indictment of the funeral industry. In *The American Way of Death Revisited* (published 2 years after Mitford's death in 1996), Mitford adopts a journalistic technique of accurate reporting with devastating effectiveness. Starting with the task of identifying, characterizing, and attracting the customer base, Mitford details everything from the analysis of the ability to pay by the bereaved, the choice of language in describing the services and products offered by funeral homes, the procedures employed in preparing the deceased for viewing, the range of caskets and their strategic array in showrooms and catalogs, to the final item: the vault and the techniques for its sale.

Characterizing the Customer

Funeral directors are acutely aware of the pending financial resources of families that are in the process of dealing with settling the estate of a recently deceased relative. Some of the resources are predictable from the decedent's history of employment. Minimally they include the death benefit from Social Security. Often there are paid-up insurance policies intended for "final expenses"; larger policies, pension benefits, and stock accounts may provide a considerable amount of cash to the immediate family. In a smaller community, the funeral home owner can calculate with great accuracy the available cash and can plan the funerary services to be offered accordingly.

Language

Funeral home directors are trained in their schooling in language calculated so as to build the confidence of the customer in the director's wise counsel. An embalmer is now a "dermasurgeon." Funeral directors have appropriated the title and role of "grief therapist," despite usually lacking any training in clinical psychology. The industry from time to time publishes lists of "in" and "out" words and phrases to be used in grief counseling: These lists are occasionally revised. Since 1916, handling the corpse has evolved from "prepare body" to "prepare remains" or "prepare (decedent's name)." Coffins have become "caskets"; morgues "preparation rooms"; a stillborn child is "your baby/infant"; the dead are now "the deceased"; ashes have become "cremains" or "cremated remains," and so forth. The word *death* is not to be used; thus, a death certificate is a "vital statistic form." Graves are "opened" and "closed" rather than dug and filled. And the deceased have not died; they have "expired." Directors never refer to the cost of the casket but rather speak glowingly of "the amount of investment in the service." And above all, cremation never occurs in a retort or oven; it is a "cremation chamber" or "vault": "language dictated by sensitivity to the bereaved relative's sensitive feelings."

Preparation of the Corpse

Different preparations are needed depending on the state of the body upon death. An individual who has had the fortune to die suddenly in his or her bed still looks gruesome: blood pools in the lowest parts of the body; sphincters suddenly lose their tonus, releasing fecal matter and urine. Many automobile deaths are traumatic, involving loss of limbs or head or torso. Still worse are the results of assault by others. Some difficult preparations are those in which death has followed torturous mutilation. The mortician is thus faced with an enormous challenge to prepare the decedent for final viewing by friends and family, seeking to erase the horror resulting from identification viewing and replace it with a final image more in keeping with the perception that "he/she looks like he/she is sleeping," perhaps the highest compliment to the mortician's artistic skill.

Because bodily decay starts rapidly, a decedent who is to be viewed (and perhaps shipped home first) must be washed and embalmed. But embalming, started during the Civil War so soldiers could be shipped home, is not the procedure of the Egyptians; its aim is to carry the deceased for the few days between death and burial or cremation during which friends and loved ones "say their good-byes." "Grievance counselors" solemnly assure those who remain behind that final viewing is healthy and facilitates the grieving process, even though there have been no adequate controlled studies that provide such evidence.

All this cosmetic work, the replacement of lost limbs, smoothing with wax and airbrushed colors

the face ravaged by injury or savagery, is necessary only if viewing is to occur. And here, social custom and expectation, fanned by such celebrated phenomena as state funerals, dictate that the closer one can approximate such a spectacle, the greater the value accorded to the deceased.

The Casket

Morticians are acutely aware that the single most profitable element in the optimal funeral is the casket. Caskets and cosmetics are essential elements in creating the illusion that the clock has been wound back to before the death event. A decedent well prepared for viewing, perhaps dressed in a favorite dress or smoking jacket, holding a Bible or pipe, wearing the rings and keys and pins of a lifetime of exemplary learning and service, all contribute to the illusion that he or she "is just sleeping."

Morticians' conferences present empirical research on how the display of caskets may be staged to increase the likelihood that a more expensive model is chosen. The array is not by cost, but presents options in an order that seems to deflect attention from price and toward appearance and quality. Tendencies to turn one way or another when entering a room full of caskets have been determined by behavioral studies: As most individuals are right-handed and tend to turn in that direction, more expensive options are placed to the right of the door to the display room. If a customer is left-handed, a door on the opposite side of the display room is the preferred point of entry, so that the natural tendency to turn first to the left will be met by the more expensive options.

The Second Casket

A major part of the illusions surrounding funerary practices is the idea that decay can be held at bay, not merely through embalming, but also through burial in "hermetically sealed" caskets placed in a brick or concrete vault, sometimes lined with lead. Individuals agreeing to these structures usually do so in the belief that they prevent air, water, worms, and bacteria from getting to the deceased's remains. In truth, the vault serves only the interests of the cemetery as it prevents collapse of the soil above the casket as the latter, and its contents, degenerate.

Cremation

Cremation of the deceased became increasingly popular after the publication of the first Mitford work. Cremation can be achieved for a few hundred dollars and does not require a casket. The dead individual can be transported directly from the death bed to the crematorium in a body bag. Ashes, depending on the wishes of the consumer, can be returned to the family in a tin box or in an urn of almost any price. Most states permit ashes to be scattered in public lands or buried in a cemetery or even a backyard.

What Is Ethical and Unethical

When it was discovered that a Tennessee man had accepted money for cremating bodies which he had piled up instead of cremating, everyone agreed that this was unethical. Unfortunately, it is not as easy to get agreement on every practice that an individual consumer may consider unethical.

The major effort of the FTC in enacting rules to regulate the funeral industry has been to stop deliberate misrepresentation by morticians of facts and laws. Telling the bereaved that embalming is a legal requirement, even for cremation, to combat the spread of infectious disease is banned, as are other practices such as not offering a detailed price list of unbundled services. But the FTC makes no requirement that individuals who seek funerary services not be unduly influenced by guilt or the pressure of peer expectations, long a requirement of informed consent in medicine and human subjects research. The result is that, given the psychological sophistication of modern marketing methods and sales psychology, the funeral industry regards itself as ethical when it gives the public what it wants rather than the minimum of what it needs.

The public needs means of disposing of the dead in such a way that public health is preserved. It needs its sensitivities served by proper respect for remains. It needs a place and time for family and friends to gather and memorialize the deceased. All else serves the dubious human characteristics of status and making atonement that is too late.

Still, allowing for the psychological manipulation that any successful salesperson of real estate or automobiles practices, and thanks to the Funeral Rule of the FTC, most practices of the funeral industry do not fall clearly into the category of the unethical. In that respect, the caveat emptor admonition is the remaining protection for the consumer.

The Not-for-Profit Way

Some 200 nonprofit, volunteer-run memorial societies in the United States and Canada provide opportunities for advance planning and guidance at the time of execution of those plans. A small fee paid to one such society entitles the member to the services of any society at the location of the individual's death. Most of these societies belong to the Continental Association of Funeral and Memorial Societies or the Memorial Society Association of Canada. They can help structure such options as a home wake, rental of a casket, and burial without involvement of a funeral home.

A final option is body donation to a research medical school. Cadaver donation is intended for training medical students and advanced study by medical physicians. Donor cards may be obtained from Continental Association of Funeral Memorial Societies, Inc. As a medical school may decline the offer, alternative plans should be made.

Funeral Music

Associating various kinds of performing arts to the most important events occurring in people's lives is a common feature of human culture. Prayer staging, singing, and dancing are commonly met at solemn occasions such as births, initiation rites, marriages, and funerals, as well as more specific rites of passage as, for example, ordination in some churches. But perhaps the association of these rites and music is nowhere as frequently met as with funeral practices, except in those religious contexts where music as a whole is forbidden, such as in the most radical tendencies within Islam. Singing and instrument playing are universally conspicuous. In Western culture, funeral music has given way to a special musical genre that is commonly called the *requiem,* from the Latin form of prayers dedicated to the deceased in the Catholic Church.

Specialists in the field of rituals as applied to funeral procedures generally distinguish between three types of rituals: (a) rituals of separation: the deceased is said good-bye to by the community as he or she leaves the realm of the living through the words of an officiant (e.g., a priest or a prayer leader of some sort); (b) rituals of translation, from the realm of the living to the realm of the dead; (c) rituals of welcome, at the threshold of the realm of the dead, once again an officiant or a group of welcomers. Music, accompanied or not by songs, can be heard at every stage of the whole set of rituals. In the Catholic Church, the rituals of separation are perhaps the most important since the contemporary funeral corteges have relinquished the pageantry of ancient times and that the burial itself, being held in open air, is rarely an occasion for much singing and music playing. Moreover, except for prominent people, the funeral ceremonies of today are often reduced to some perfunctory praying and speaking. In most cremation ceremonies, however, records are played, which are chosen in accordance with the deceased's tastes. This now occurs also in some religious funerals.

Requiems, From Dufay to Britten

At the beginning and at the end of the sung Mass of the Dead, the officiant begins his last oration by the words "*Requiem aeternam dona ei, Domine*" (Give him/her, Lord, eternal rest). The word *requiem* applies to a special kind of mass, to which many illustrious composers have given their names. Mozart is the best known of them. But others such

as Verdi, Berlioz, and Fauré are also celebrated. During the early stages of Christianity, at funeral services, music for the dead was performed in plainsong. The first original *Mass of Requiem,* of which the score is now lost, is said to have been composed by Guillaume Dufay (1400–1474), a musician from northern France, for his own funeral service. But there are more ancient melodies associated to these Latin texts, such as Gregorian ones, dating back to the 7th century. Traditional liturgical music was often used for scoring the *Requiem* text. As a rule, the lyrics of the Mass for the Dead differ from those of the ordinary Mass. They begin with the word *Requiem* and replace the *Gloria* by a "sequential" beginning with the famous *Dies irae* (Day of Wrath), and the *Credo* by an *Offertium.* In the A*gnus Dei* section, the first line "*ora pro nobis*" is replaced by "*dona eis pacem,*" and the second one, "*dona nobis pacem*" by "*dona eis requiem sempiternam.*" A last section, "*Lux aeterna luceat eis*" (Let everlasting light shine on them) concludes the Mass.

One would expect the musical color of the *Missa de Requiem* to be generally a somber one. This is not always the case, though some of the most famous examples bear a tonality of grief: those of Mozart, Michael Haydn, Cherubini, and Dvorák. But there are exceptions such as Verdi's, where to some extent grievance replaces grief, and Fauré's, which he wrote at the occasion of his mother's death, in which the atmosphere is one of sweet acceptance and resignation. Many of the great composers never wrote a requiem, for example, Beethoven or Johann Sebastian Bach (perhaps because Bach was a devout Protestant). However, Bach wrote a *Mourning Ode* (*Trauer Ode*), and Beethoven a *Funeral March,* ordinarily played in London at the Ceremony of the Cenotaph. Many musical works are related to death and mourning, such as *Funeral Music for Queen Mary* by Purcell, *Funeral Music* (a homage to Béla Bartók) by Lutoslawski, the second movement of Beethoven's *Eroica Symphony* ("Marcia funebre"), Wagner's "Death of Isolde," Hindemith's *Mourning Music* (on the death of King George V), and Penderecki's *Threnody* "to the victims of Hiroshima."

One should also note musical works bearing the title of *Requiem,* but which do not refer to the canonical words of the Latin Mass. Best-known examples are Brahms's *Eine Deutsche Requiem* (with a libretto in German), Delius's *Requiem* (on texts by Nietzsche), and Stravinsky's *Requiem Canticles*. Britten's *War Requiem* is special in that it is set on nine poems by the World War I poet Wilfred Owen in interpolation within the lines of the Latin requiem mass. The feeling of death and grief also pervades a great part of Western music, as in many lieder by Schubert or in Mozart's Masonic *Trauermusik*. Death scenes appear often in the opera, be it Verdi's *Traviata* or Puccini's *La Bohème*.

One may distinguish requiems composed for all the dead from those dedicated to deceased people in particular as individuals or in group. To the first category belong Mozart's and Berlioz's requiems. To the second, Cherubini's one in the memory of King Louis XVI, or as Britten's *War Requiem*.

The music of the *Missa pro defunctis,* apart from its liturgical significance, can also be considered as a musical genre per se, comprising many pieces that are often played at concerts separately, like other kinds of religious music, and masses in particular. It has been stated that some requiems such as those by Berlioz or Verdi were more appropriate to concert rather than church use. On the other hand, musical pieces that do not necessarily convey a sense of grief can be heard at funeral services, sometimes denoting a somber tone, sometimes not.

In contemporary services, recorded or actually performed music may include secular pieces or even pop songs. In 1993 at the funeral service of King Baudouin of Belgium, no requiem was performed but rather a patchwork of classical pieces (Franck's *Panem Angelicum,* among others) and secular tunes from various origins. Postmodernity was well represented at the ceremony, as it has been in many other solemn occasions such as weddings or coronation pageants.

Other Religious Settings

In most religions some kind of music, instrumental and/or sung, usually plays a great role in mourning ceremonies. As a rule, music is called for in many kinds of rejoicing, private or collective, such as weddings, graduations, or dedication ceremonies. But music also is called for in occasions of sorrow, mourning ceremonies being only one example of these occasions. Recollections and various kinds of

tragic celebrations are also accompanied by music in a majority of societies.

Variants of the *requiem* are to be found in the Protestant, Anglican, and Orthodox branches of Christianity. Among the Jewish communities, a special *Kaddish*, sung in Aramean, is performed in funeral services, normally by the local cantor. In Islam, music as a whole is forbidden, but there are prayers said by an imam, or prayer leader, at the mosque. These are more or less psalmodied, which can make them rather akin to *Sprechgesang*.

In other less developed cultures, for example, in sub-Saharan Africa, funeral rites encompass songs and instrumental music, especially percussion. Funeral songs are related to war songs and are also accompanied by dances. These songs are often violent, calling for the reinstatement of a previous social order that death has disturbed. As on other festive occasions, the original chaos is staged from which the social order, surpassing the occasional chaos generated by death, is supposed to evolve. This is especially true of the chiefs' funerals. Anthropological studies of death rituals abound, showing that beneath the many various stagings one may encounter through the vast human realm, a common scheme is always lying. It is the same in every known culture, as well in highly "civilized" societies as in "traditional" ones.

Religious music used to be a compulsory component, as it may be thought obvious, in religious funeral services. Its function was threefold: (1) awarding the deceased a publicly stated religious accompaniment, (2) reasserting the religious affiliation of the deceased, and (3) providing a "beautiful" environment to the occasion. In one of the rare books on death and its social treatment, which rarely deals with the presence of music in funerals, the author M. Bradbury has one of his witnesses declare, "The funeral was absolutely beautiful. We had all the most wonderful music, and the church was full, and that was very comforting" (1999, p. 87). So the function of music, be it a way to underline the "farewell" ritual or the "welcome" ritual, is to bestow an aesthetic dimension that broadens the collective scope of the latter. In music more than in words, the assembled community of mourners is really called to "commune" and also to communicate its sorrow to the external world. Music helps to gather the people around the still-fresh memory of the deceased and is a token of the people's common grief. Thus the music to be sung and/or listened to is an important part of the funeral ceremony and must be chosen carefully.

In nonreligious funeral services, musical pieces are drawn from various sources. For example, Sir Elton John performed a remake of his song *Candle in the Wind* at the funeral of Diana, Princess of Wales. A kind of farewell concert can be set up, with some pieces borrowed from the deceased's favorites and others from a musical *doxa*. This is especially true of European cremation rituals, where pop music or rock pieces can be heard, along with popular classical songs such as Albinoni's *Adagio* (that were at one time commonplace) or popular songs. The goal is again to celebrate not only the deceased's memory through his or her musical tastes but the community's concern with the individual's death and the meaning of the community's convening around the dead body. Music then brings remembrance of one of the most elementary meanings of "religion," which is to bring together.

When music is played at a particular ritual, the corpse of the deceased need not be present. Some remembrance services are often held long after the deceased's departure. Then music, especially sung music, is provided by the community or special members, such as monks, for example. Music is given the role of maintaining the memory of the dead as well as the continuation of the community. Its virtues of repetition, of reinforcing eulogies, of imposing silence to the listeners suit well the need of evoking and summoning the dead in order to protect the community against any threat of the dissolving time. This is the function of any ritual, at any level of human togetherness.

Funeral Pyre

A funeral pyre is a wooden structure built over a fire and used in funeral rituals for the cremation of a corpse. The raised structure allows for air to flow underneath the flames, but it also allows for better viewing of the pyre in ceremonies attended by mourners. Outdoor cremations, a feature of aristocratic funerals in the ancient Near East, Carthage, Greece, and Rome, are no longer performed in the West but are still common in India.

Cremations were performed in the West in the Bronze and Iron ages alongside inhumations. Pyres and funeral biers are attested in ancient Greek and Latin literature, and depictions appear on Greek pottery from the archaic and classical periods. In Homer's *Iliad* Book 23, Patroklos is cremated on a pyre after the sacrifice of horses, dogs, hostages, and the placement of gifts and armor. The live cremation of Croesus, King of Lydia, on a pyre in Herodotus's *Histories* (Book 1) is interrupted by rain and serves as a cautionary tale on divine retribution. In Greek mythology, the hero Herakles was cremated as a vehicle for his apotheosis (see Euripides' *Herakles*). Following Homer's lead of incorporating cremations within epic narratives, the cremation of warriors on pyres, following a battle, became part of the funeral and burial trope in Latin epic poetry. The individual and mass cremations of warriors are found in the epics of Ennius, Vergil, Ovid, Lucan, Valerius Flaccus, Statius, and Silius Italicus.

In ancient Rome, cremations and inhumation burials were performed contemporaneously. The archeological and historical evidence for cremations is extensive. For cremations that took place where the deceased would be buried, a corpse was placed on a bier (*feretrum*) or pyre (*rogus*) and after the cremation, the place of cremation was covered with solid to make a mound (*bustum*), which could be covered by a funeral monument. To mark the spot where Julius Caesar was cremated, however, a temple was built in the Roman Forum that signified his apotheosis. If the cremated remains were to be stored elsewhere, the ashes and bone fragments were collected and placed in an urn, normally with a finger of the deceased, which was removed before cremation. The urn could be deposited in mausoleums, family tombs, funeral monuments themselves, including sarcophagi, or in burial niches (*columbaria*), all of which were located outside the urban center of Rome (marked by the religious boundary that encircled the city called the *pomerium*) until the Imperial period when the cremated remains of Trajan were deposited in a column (dedicated in 113 C.E.) that still stands in his forum. Due to the amount of wood needed to sustain an appropriate temperature for cremation over several days, the ceremony was expensive and time-consuming, even for modest cremations. Interruptions due to inclement weather were common, and the ceremony would be resumed once the weather improved.

Pyres were associated with the Roman Imperial funerary ritual (from the 1st to the 3rd centuries C.E.). The corpse of the emperor Augustus was attended by his wife Livia as it burned on a pyre for several days. As rituals associated with the cult of the emperor increased, the corpses or wax images of later Roman emperors were cremated on pyres as a vehicle for their apotheosis. A wax image of the emperor Pertinax, for example, was placed inside the second level of a multitiered pyre (*ustrinum*), with doors and windows on the upper level, that was decorated with marble, gold, statues, tapestries, and paintings and was topped with an image of the emperor in a golden chariot. During the cremation, a bird was released to signify the emperor's apotheosis.

The early Christian church established a doctrinal preference for inhumation burials over pagan cremations because of resurrection of the body which contained the Holy Spirit. The growth of inhumation burials in catacombs points to the need to avoid Imperial attention prior to Constantine's conversion, but it also indicates the decline of cremations except for members of the pagan elite who still practiced cremations. The long-standing Christian practice of inhumation led to the decline of cremations in western and eastern Europe until their revival among Protestant denominations in 19th-century Britain and the United States in indoor crematoria. The Catholic ban against cremations was lifted in 1963, but ashes must be buried in a cemetery. Originally fueled by wood or coal, contemporary cremations are performed in furnaces fueled by natural gas or propane and regulated by codes that specify the height

of furnace chimney stacks and the distance between crematoria and residential areas. The body may be burned in a cardboard or combustible casket. The collected remains are called ashes or cremains.

Cremations on a pyre remain an important rite in many religions, including Hindu, Sikh, Jain, and Buddhist funeral ceremonies. Traditional Hindu cremations, for example, take place outdoors: After the ritual preparation of a corpse, the corpse is carried to a holy place and placed on a pyre that consists of sandalwood and palasa wood. The pyre may be a structure built on land or a platform that floats on water. The head of the corpse points north and is cooled by water to relieve the deceased from any agony. Following the cremation, bones and ashes are scattered in the Ganges or brought to areas sacred to ancestor worship. Orthodox and liberal practices vary: It is becoming increasingly common, especially in large urban centers, for a corpse to be cremated in a crematorium but for the ashes to receive death rituals at a holy place.

Funerals

The funeral has long been a component of society's attempts to adjust to and cope with the loss of one of its members. Traditionally, it has served as a ceremony acknowledging death, as a religious rite, and as an occasion to reassure and reestablish the survivors' social group after death. The funeral serves to commemorate life as well as establish a ritual for disposal of the body. The funeral service itself serves at least two purposes: completing the final placement of remains (its secular function) and confirming public recognition of the deceased person's transition from life to death (its sacred function).

The funeral serves to make real the implications of death, and it assists in the individual, family, social, and spiritual integration of living after death. To the extent that funerals are typically short-lived events, such full integration via the funeral may not be possible in many cases. Grieving obviously goes on for some time after the funeral, and thus the funeral may help initiate, but not necessarily maintain, grief work.

The Evolving Funeral Ritual

The funeral in America has transitioned from a rite of passage, understood by the attendees as being for the benefit of the decedent, to what is primarily a social ritual, understood by attendees as primarily for the benefit of the bereaved. The work of Philippe Ariès, a French cultural historian, dealt with historical shifts in attitudes toward death, tracking funeral practices from the 18th to the mid-20th century.

In the era of sacred death, the 17th and 18th centuries, death was associated with the dying person taking leave of this world on the way to the next, and there was a clear distinction between the religious funeral (marking this metaphysical passage) and any civic event that might follow it. Over time, the religious and civic ceremonies began to merge, but the sacred significance remained inherent in the conception of the funeral.

During the era of secular death, beginning with the 19th century, urbanization brought about the specialization of death professionals, who were often nurses for body preparation and furniture dealers for casket provision and interment. This eventually gave way to the development of the mortician/funeral director occupation. Funerals during this era took on more secular functions, including wealth display and the fulfillment of expected social roles. Whereas the focus of the funeral in the era of sacred death was upon the deceased, funeral processes during the era of secular death focused on the bereaved.

Finally, the era of avoided death, from post–World War II to the present, is defined by modern

medicine's victories in the face of many diseases. Indeed, until this occurred, the frequency of untimely deaths undermined a person's ability to ignore the continuing possibility of encountering death in everyday existence. With life expectancy increasing, and with the growing professionalization of death care services, the vast majority of Americans could now live much of their lives as if death did not exist. This avoidant stance toward death is then played out in the funeral process, in which mourners maintain considerable distance from the ugly realities of death and decomposition.

These changes have coincided with a pluralistic shift in American society, in which individuals live, work, and socialize with others who do not necessarily share their religious/metaphysical beliefs and values. So, when someone dies, the community relevant to the death may represent many religions, many attitudes toward death, and many funeral customs derived from their respective families and subcultures of origin. This evolution has yielded a greater emphasis on the sociological function of the funeral ritual. Although the other functions continue to have impact, the social coming-together represented by the funeral and the direct expressions of social support for the primary mourners constitute a large portion of the funeral events.

Some have suggested that the multicultural context of American society—lacking a unifying and shared mythological framework—will lead (indeed, already is leading) to a "ritual-less" society. As it appears likely that American society will continue to evolve toward greater diversity of values and beliefs, such a prediction should be taken seriously, and its impact on the funeral ritual should be considered. However, since the attacks of September 11, 2001, American culture has shown a clear affinity toward ritualized social action geared toward memorialization of death. This trend was already beginning to emerge following the Oklahoma City bombing in 1995; the memorial park now open in that city might be understood as a continual funeral ritual. It is worth noting that this reemergence of mass-culture ritual has taken place without a corresponding homogenization of religious/metaphysical belief systems. Thus, it appears that societies can develop meaningful shared rituals that are based upon shared experiences rather than commonly held religious beliefs.

In this light, it should be no surprise that historical and individual variations exist with regard to how Americans view funeral processes. In addition, the funeral industry has been criticized as it has served (and perhaps directly influenced) these variations.

Some of these critics, for example, feel that American society has given control of the funeral to professional funeral directors, wherein such persons are now viewed as experts whose functions are to both stimulate and satisfy the needs of bereaved persons (e.g., by providing services that both reflect and stimulate demand) and to maintain the illusion that death represents both a painless state and the end of a fulfilling life. This may explain the desire to view the corpse as peaceful, where the funeral director's control over death is emphasized. Freed of the responsibility for preparing the body for viewing, individual consumers may feel license to be critical of those whose services they have purchased, further distancing them from the harshness of death. This distancing reflects the bureaucratization of death, and the ambivalence that many feel is embodied in the power that the funeral director enjoys in possessing the body, while his or her embalming "protects" the bereaved person from the realities of death. This power permits the funeral director to exert considerable control over the funeral ritual itself. The growth of the modern hospice movement, debates over the ethics and morality of euthanasia, and attention paid to the morality of physician-assisted suicide all reflect the dissatisfaction that persons feel in ceding control over the dying process to others, emphasizing the quality over the quantity of life in so doing.

Others are concerned about the dysfunctional nature of the funeral; its commercialistic and exploitive nature undermines its meaningfulness as a ritual to celebrate the life of a deceased loved one. As customers are ultimately at a disadvantage due to a lack of knowledge about what to do when someone dies, and due to the emotionally vulnerable state in which they make funeral decisions, they often make decisions that are hasty or in response to pressure from the funeral director. For these reasons, the funeral fails to meet the spiritual and interpersonal needs of the grieving family, often operating in a void with respect to its relationship to the community.

In light of such criticism, it is interesting to observe that many studies suggest that the public is, generally speaking, satisfied with the funeral ritual; there is a general belief that the funeral industry does a credible job in meeting their needs. Indeed, the vast majority of persons state that they are satisfied with the quality of funeral services they have received. Yet, only a minority indicate that those in the industry were helpful, compassionate, caring, and competent.

With regard to desired changes, the most frequently mentioned issue is, not surprisingly, cost (people spend an average of $4,000–$6,000 on a funeral). Indeed, the 1984 Federal Trade Commission Funeral Rule prevented funeral directors from quoting a single price for the overall funeral, requiring funeral homes to provide customers with an itemized list of charges and descriptions of available caskets, while asserting that funeral directors cannot prevent customers from purchasing a casket from someone other than the funeral director.

Attitudes Toward the American Funeral: Historical Variations

Little research has been conducted on the American funeral process, and much of the information that is available is several decades old. More recent evidence suggests that views of the funeral's relationship to death and grief have changed, leading to changes in both the American funeral and the ritual responses to death, which may make funerals more effective resources for coping with death and bereavement.

Regarding cohort shifts in funeral attitudes, a 1967 nationwide survey of funeral directors indicated that a funeral in America was perceived differently by different people. This is because a funeral does not take place in a vacuum, but rather is dependent on regional and cultural beliefs, customs, and attitudes. An overall cultural shift in beliefs and attitudes about death, dying, and bereavement would therefore necessarily affect attitudes toward funerals and assessments of their purpose. There is evidence that such shifts have indeed occurred, wherein over a 30-year period persons were more likely to have thought about such practices as organ donation, were more likely to feel "indifferent" about having their bodies embalmed, and were no more likely to have made funeral arrangements ahead of time. This suggests that over historical time, attitudes toward the traditional funeral ritual as a means of bodily disposal or affirmation of the life of the deceased person may have become somewhat more negative. Developments in health care technology, for example, could be interpreted as a reflection of a general reluctance to accept the inevitability of death and may reflect a lessening of the importance of the funeral's sacred role. Historical shifts in demographic factors such as mortality rates or persons' economic status could also influence variations in funeral attitudes.

Attitudes Toward Funerals: Individual Variations

There appear to be individual differences in attitudes toward funerals and funeral preferences, wherein nonreligiously affiliated persons tend to be more critical of the funeral process, and persons who are more highly educated and who have higher incomes tend to be most critical of funeral rites and ceremonies.

As people vary in age, they also vary in the likelihood of having attended a funeral. Prior experience, tradition, and general knowledge of funeral practices, then, impact one's expectations of a funeral ceremony. Cohort membership also affects one's expectations and attitudes toward funeral ceremonies and the processes involved in organizing them. Specifically, middle-aged and older persons tend to hold more favorable attitudes toward funerals and funeral directors, which may be due to young persons' often less traditional approach to dealing with grief as well as covarying with the number of funerals one has attended.

Attitudes toward funeral rituals also vary with religious, ethnic, and socioeconomic factors, such as the actual merchandise one purchases (e.g., the type of casket), the nature of the disposition of the body, and the funeral's overall cost. A family's means of absorbing such costs would likely affect its attitude and perception of the entire experience. Other influences on funeral attitudes include who oversees the final arrangements and the level of that person's prior knowledge of how to make such plans.

Intrusive problematic events can also influence or distort the funeral process and one's experience

of it. Family tension and discord, for example, add stress to an already difficult time for mourners. For example, a lack of consensus on matters such as deciding upon an open- versus closed-casket ceremony virtually guarantees someone will be dissatisfied with the service. Nonetheless, mourners who are able to find solace in the funeral cope better in the long run, even if the funeral was marred by one or more problems.

Gender may also be related to one's attitude toward funerals. For example, regarding funeral directors, the public often is more comfortable in dealing with women. Many of those making arrangements are widowers and may therefore prefer talking with female funeral directors. Studies suggest that men tend to be most concerned with the costs associated with the funeral, whereas women tend to be more concerned about the appearance of the body and with social relationships related to family and friends.

Persons' attitudes toward funerals are likely to be more positive when the funeral and director(s) can effectively aid in the venting of emotions and when they respond adequately to the psychological needs of the survivors. The question of funeral beneficence, then, is likely to covary with individual survivor characteristics and the circumstances surrounding the death. Specifically, a high-grief death, such as the unexpected death of a child, would greatly increase the chance of potential difficulties in psychological adjustment, while the death of an elderly relative, which is more likely to be an expected one, could result in less psychological harm to survivors. As involvement in funeral rituals may help the adjustment of such persons, the therapeutic effect of funerals may be the greatest when the death was traumatic, as in suicides, or in the case of sudden or violent deaths.

Some researchers have argued that funerals now better reflect the psychosocial needs of both the mourner and the community in which the mourner is embedded. Persons who vary in age also vary in the likelihood of having attended the funeral of a friend or family member, and on this basis alone, one might predict that there would be age differences in perceptions of the funeral. Likewise, persons who are members of different cohorts, who were born in different historical times more than likely have had different experiences with loss in the context of the funeral.

Age cohort differences in perceptions of funerals might also be important from a marketing perspective. Those who are bereaved or who have yet to lose a loved one will either be the direct recipients of funeral services (and consequently may express a preference for a particular type of ceremony in anticipation of their own eventual deaths), or will seek out such services in the event of the death of a friend or family member. Likewise, variations along ethnicity, gender, whether the survivor had experienced a sudden loss, whether the death was violent, or whether the deceased had died in a manner that might undermine the support available to the griever via the experience of disenfranchised grief all must be considered in understanding persons' orientations to the funeral and/or its benefits to individuals and to the community.

Outward symbolic manifestations of grief that are culturally determined (e.g., having flowers to symbolize the continued existence of someone who has died, being able to view the embalmed body in a casket, being part of the funeral procession to the burial site) may be rejected by younger adults in favor of cremation and/or a memorial service, organized not by the funeral director but by family, friends, or both. The latter expressions of grief may not only be less expensive, but may also give family and friends more control over what happens, when it happens, and what is said by whom than might be possible when the funeral director takes the initiative in structuring the funeral service, such as in suggesting a range of caskets, music, flowers, the location of the funeral, alternatives to a traditional service, or the burial site itself. One might also speculate that younger persons, who have had fewer losses with which to deal, are consequently less knowledgeable about the funeral industry. Simply learning about what it is that funerals and funeral directors do and do not do might mitigate such misperceptions.

Funerals of the Future

Given the complex, culturally embedded nature and function of death rituals, it is impossible to predict the exact direction of their continued development. Certainly, there is a growing movement toward funerals that are more personalized, as in the creation of a CD documenting the life of

the deceased, reflecting the funeral's sacred function. Likewise, a growing trend toward convenience is reflected in the "drive-thru" funeral, where mourners can pay their respects in the comfort and convenience of their car and view the embalmed corpse on a television screen, with an accompanying eulogy on the radio. Another variation reflecting the funeral's secular function, which might gain in popularity, involves a novel method of body disposal, wherein the body is submerged in liquid nitrogen coupled with ultrasound wave bombardment (to ensure thorough internal freezing), and then nearly all the liquid is removed from the remains via a vacuum process. The resulting remains consist of an odorless organic powder that can be safely dispersed onto soil with no toxic release. Other, perhaps less extreme possibilities for body disposal and funeral rituals involve cremation and memorial services, respectively. Much like the evolutionary survival of specific consumer electronics, the particular trends that survive and become accepted standards will likely have much to do with effective marketing and happenstance rather than functional superiority, reflecting a greater awareness of mourners' needs and preferences when a loved one dies.

Funerals, Military

Military funerals are funerals for any veteran other than those individuals who left the military with less than an honorable discharge, for soldiers who died on the battlefield, and for other well-known military figures. Customarily, when the president or prime minister or monarch of a nation dies, he or she receives a military funeral. The funeral ceremonies vary based on the rank of the deceased, with the highest honors going to general officers and high-ranking civilians who supervise the armed forces, such as the secretary of defense or heads of state.

History of Military Funerals and Rituals

While military funerals have been provided for soldiers probably back to the times of the Greek and Roman empires, the military funeral, as it is practiced in the United States, draws its basic elements from the French and British military funerals of the 18th and 19th centuries. For example, the practice of draping the casket with a flag began during the Napoleonic Wars in Europe (1796–1815). The firing of rifles over the gravesite began as a practice of firing rifle volleys during the 18th and 19th centuries that were intended to announce that each side had cleared its dead from the battlefield.

The common practice was to fire three volleys to verify that the clearing of bodies was complete.

The 21-Gun Salute

The 21-gun salute, reserved for those receiving the highest honors, has a more complicated history. Initially, salutes of any kind, such as the hand-to-forehead salute as practiced in most militaries around the world, simply indicated that the one offering the salute placed himself or herself in a position of being unarmed. But gunfire salutes have been used since guns were first used in battle. Gun salutes were fired as a manner of greeting from one contingent of soldiers to another. Historically the British insisted that the first salute be fired by the "weaker" country. However, with the rise of the notion of equality of nations, the international practice became one of a gun-for-gun salute.

The British had actually begun the official gun salute based on the use of seven guns. Over time, the British salute evolved from 7 guns to using 21 guns. In the United States, the practice was to fire one gun as representing each state in the Union. With growth of the Union, by 1818, the salute had reached the use of 21 guns. This number continued to grow but, in 1841, the United States reduced its formal salute to 21 guns. But there remained a great deal of confusion in various American states concerning how many guns were to be used. The United States adopted a British suggestion that America join the practice of most nations in officially recognizing 21 guns as the international salute. On August 17, 1875, the United States adopted the 21-gun salute and the practice of "gun for gun" in the salute. From that time on, the 21-gun salute was a high honor at military funerals reserved for those of very high rank.

"Taps"

Another feature of American military funerals is the playing of "Taps" by a bugler. Before 1862, the official call at the end of the day (or at the end of a soldier's life) was "Tattoo," also known as "Lights out." "Taps" was written by Brigadier General Daniel Butterfield at the end of a horrendous day during the Civil War. He wrote out the melody while he was wounded. The piece was meant as a tribute to the 600 men he had lost from his brigade that day. Although the tune was written by a general in the Union Army, by the end of 1862, the call was used by both Union and Confederate troops. "Taps" was officially adopted by the United States Army in 1874. It became known as "Taps" because if a bugler was not available at the end of day, the melody was tapped out by a drummer. The sounding of "Taps" at military funerals began in 1862, the same year it was written. The haunting, reverential melody seems especially appropriate to recognize the end of soldiers' lives, the end of their days on earth.

Standard Military Funeral

At this time, a standard military funeral includes the services of a military chaplain, a casket team (at least two active members of the armed services—this includes the Reserves and the National Guard as their members may be tasked with funeral detail), a firing party, a bugler or electronic recording of "Taps," and a flag to drape the coffin. Provided by the Department of Veterans Affairs, the flag will be folded in an honors ceremony and presented to the next of kin at the gravesite. For officers and warrant officers, the casket team will be replaced by a casket platoon and a military band may be provided. For some officers, especially those of high rank, the casket may be placed on a horse-drawn caisson. When the burial is of a colonel or higher rank, or a former president or secretary of defense, a riderless horse may accompany the caisson. The riderless horse represents a fallen leader. There may also be a 21-gun salute for a president or former president.

At the funeral ceremony, the coffin is draped in a U.S. flag. At the gravesite, the rifle volley is fired (in the case of a member of the U.S. Navy, a cannon may be used), and "Taps," with the bugler placed some 30 to 50 yards away, is played. At present there is a paucity of buglers who are enlisted in the armed forces and, as a result, a recording of "Taps" is now played at many military funerals.

At the end of the military ceremony, the flag is folded in the military manner and is presented to the next of kin. When presenting the flag, the member of the funeral detail states, "As a representative of the United States Army [or Air Force, Marine Corps, or Navy], it is my high privilege to present you this flag. Let it be a symbol of the

grateful appreciation this nation feels for the distinguished service rendered to our country and our flag by your loved one." Although all funerals are a way for family members and friends to say a formal and dignified good-bye to the deceased, the additional honors of a military funeral make this a most solemn occasion.

Funerals, State

A state funeral is a public event held in honor of a figure of national significance—most commonly heads of state. There is no legal requirement for a funeral, as burial or cremation can be arranged without any service or congregation, but the continuing popularity of the ceremony is testament to its efficacy as a ritual focus.

The funeral is a liminal event; a rite of passage with coded behavior experienced outside of routine and in the realm of social transition. The immediate nature of rites of passage, and their concrete expression of ephemeral reality, serve as a vehicle for heightened emotions. Although mourning varies from culture to culture, common elements of the ritual practice are (a) the expression of community, (b) the reestablishing of social order, and (c) public expression of private grief.

The Expression of Community

State funerals, due to their civic dimension, enact social transition beyond the private grief of bereaved family and friends. As political rituals, state funerals serve as evidence of value integration, an expression of integration, a mechanism of integration, and a means to constitute integration.

There are a range of performance elements within state funerals, including lying in state, the funeral procession, the funeral service, and the burial, all of which can be used to signal particular cultural values. It is possible to view the state funeral as a performance-based expression of social belief. As such, state funerals are "theaters of power" that function as an occasion to mythologize an individual in a manner that serves the social group.

Mourning rituals of ancient Rome demonstrate the mythologizing of the individual within the context of the community. The accomplishments of the deceased were celebrated with those ancestors. Often elaborate funeral processions took place with hired mourners and a funeral oration that served to publicly reaffirm shared cultural values. The Roman funeral celebrated loyal service in public office and can be seen to honor both the individual and the authority of the state. Katherine Veredery identifies the continuing politicization of the dead body, suggesting that contemporary nation-states also use a funeral event as an opportunity to review national history through the lens of an individual life.

The founders of the United States initially avoided the pageantry of state funerals due to the resonances with British rule. Although William Henry Harrison was the first American president to die in office, Abraham Lincoln's funeral in 1865 is observed as a seminal ceremony, as technology allowed the news to spread quickly across the country, encouraging national, collective mourning. Lincoln was not a popular president, but his death occasioned the rehabilitation of his reputation.

Funerals are powerful rites of reconciliation that may dispel controversy and promote a sense of public accord. In death, Lincoln represented a martyr, and his assassination was seen as an attack on the American people. It is noteworthy that the grandeur of Lincoln's funeral represented an attempt to use the occasion as a restatement of American values. The organizers sought to reach

out to as wide an audience as possible and allow for a sense of catharsis through engaging the drama of the funeral rite. Lincoln actually had a number of funerals. His body travelled via a funeral train that stopped in 12 cities where the body lay in state, as well as passing through many more where people gathered on station platforms to mark his passing. A number of local ceremonies took place along the route, with community members constructing their own memorials. Thus, Lincoln's funeral is an example of a state-orchestrated event that was used to mediate between local and federal authorities.

Sensitivity to the need for communal catharsis was displayed during the funeral of Mahatma Gandhi in 1948. The Hindu tradition is to cremate those who die and scatter their ashes in rivers or the sea after 13 days. However, the government decreed that Gandhi should be given a state funeral which, despite the swift arrangements, was a large-scale event. Gandhi's ashes were then sent to towns and villages across India so that local communities could mourn the leader. This set up an unusual dynamic as not all the ashes were returned. Indeed, some of the urns were held by the public in bank vaults—a striking example of the commodification of the dead body.

Reestablishing Social Order

The bringing together of community around the funeral event allows for a reestablishment of public order, which authorities may use for their own ends. The Medici dynasty (13th–17th centuries), for example, made use of funeral services to consolidate their political power during the Renaissance. The Medici *Esequie* were based, in part, on an ancient Roman ceremony, with particular attention to staging and audiovisual effects. Much use was made of candles, due to the positive associations of light and flame developing from ancient Rome. Unlike the Roman ceremonies, the Medici rites incorporated the Christian belief in an afterlife, although the Esequie was not a purely religious ceremony. Like many contemporary state funerals, it blended the spiritual and the secular, traditional and contemporary in order to maximize its impact. The Esequie was a political statement that focused on the golden age of Medici rule in order to consolidate their authority as ruling elite.

Admiral Nelson's funeral is a British example of a power struggle contained within the ritual structure of a state funeral. Nelson died on October 21, 1805, while on board HMS *Victory*. The decision was made to break with tradition and not bury him at sea but to preserve his body and take it home to honor with a state funeral—a rare event for someone not of royal blood. Considerable planning went into the 5-day funeral celebration held in January 1806, yet Admiral Nelson's popularity was perceived as a threat to the monarchy, and the King's allowance of a state funeral may be seen as an attempt to win over the masses. Nelson's funeral, like the Medici events, was a performance influenced by the theatrical conventions of the day, and its staging served the political agenda.

Instead of a family member, the admiral of the fleet was appointed as chief mourner, which may have been an attempt to promote the idea that the British Navy was the heir to Nelson's legacy. The organizers were sensitive to the desires of the populace and, due to public pressure, a decision was made to include sailors from the *Victory*. The funeral plans were also modified to fulfill the public desire to view the body of Nelson as it was transported through the streets. Public witnessing is a key element of the state funeral and can be understood in terms of the psychological drive to look upon death and with the ritual object of the coffin as a focus for collective community grief.

Nelson's coffin was decorated to celebrate his life and victories and was theatrically framed during his lying in state by trophies, candles, and six mourners. The mourners were arranged in a manner deemed to be appropriately somber to act as models for public behavior, as the authorities were concerned about rioting because the death of popular heroes can be a trigger for public unrest. The funeral procession was also designed as spectacle with a funeral car that represented the *Victory*, modeled on the pasteboard ships used in the contemporary theaters. The theatrical element was highlighted by the fact that tickets could be bought for seats in the stands that lined the route. There was also raked seating for the funeral service at St. Paul's Cathedral, which was artificially lit to ensure the audience had a good view of the ceremony.

Public Expression of Private Grief

The state funeral also can provide a framework for the public expression of grief. The motto for the authorities dealing with the funeral of Mao Zedong (Mao Tse-tung) was "from grief into strength," and people were urged to take the opportunity to pledge themselves to continuing the cause of the leader. During his lifetime Mao had proposed that he should be cremated in order to avoid superstition and ritual but, in death, his body was claimed by the Communist Party and shaped by the politics of legitimation. The first announcement following the death of Mao was a statement reiterating Communist policies. This was followed by information about arrangements for the mourning services—to which no foreign dignitaries were invited. Following a period of lying in state, a memorial rally was held and broadcast throughout China as people all over the nation stood at attention for 3 minutes of silence. There was an outpouring of grief—which some critics argue was a result of people not being able to mourn their own families during the Cultural Revolution—and the authorities sought to channel this emotion into oath-taking ceremonies in which people pledged continuing allegiance to the Party. After the mourning services, Mao's body was housed in a memorial hall that commemorated his contributions to revolutionary history.

Reference to tradition is an important element of a state funeral and, when planning her husband's funeral, Jackie Kennedy sought to duplicate elements of Lincoln's funeral in a manner that suggests an understanding of the potency of linking to icons of power. There were, however, considerable differences in the funerals of the two presidents, as a result of modern technology. In the 1960s the mass media allowed for millions of people all over the world to witness the funeral of U.S. President John F. Kennedy. Television also offered continuous coverage of developments that could meet the desire to witness, but also, as Harry Garlick suggests, could act as an "intensifier" to accelerate the movement from shock, through grief, to the resumption of normal social life. Victor Turner states that ritual serves an important social function in terms of reintegration and that Kennedy's funeral offered a ritual closure to the distress following his murder. The presence of the television cameras allowed for intimate gestures to be captured, for example, John Kennedy Jr.'s salute to his father that was held to communicate traditional American family values. The television coverage may have created a false representation of events in that it framed particular elements at the expense of others and presented a more polished appearance than actuality.

Takashi Fujitani goes so far as to describe the funeral of the Showa Emperor in Japan in 1989 as a ritual made for television. All Japanese were encouraged to mourn appropriately. As with many state funerals, the government declared a national holiday. Shopping centers and businesses closed, and 10,000 people, including international dignitaries, attended the 2 hours of religious and state funeral rites; many more watched the ubiquitous television coverage.

The funeral of Diana, Princess of Wales, in 1997 was also a large-scale media event, but it functioned in a different manner to the Japanese state-sanctioned mourning process. The media influence began with the articulation of public dissatisfaction with the initial state response to Diana's death and the plans for her funeral. As in the case of Nelson, plans were adapted in order to meet popular desires, with the result that the Princess was honored with, in all but name, a state funeral. A martial atmosphere was avoided and representatives of significant charities were included in the funeral procession. This can be seen to have the same populist intent as the Mexican state funerals of the 1880s that included groups of workers in a manner that was designed articulate democratic principles. As "the people's princess," Diana was mourned by representatives from the community who reflected her humanitarian values. The democratic intent was also demonstrated by the erection of large television screens that allowed the public gathered outside Westminster Abbey to follow the ceremony.

It seemed, however, that merely witnessing events was not enough to hold the public's outpouring of grief, and Susanne Greenhalgh discusses the "spontaneous shrines" of flowers, photographs, and candles placed at public sites—particularly the palaces in London. These can be seen as an expression of the tension between the official ceremonies and the desire to enact personal rituals as a means to perform private grief in public.

The death of a public figure may evoke heightened emotion. Through association, people may

become aware of their own mortality, and the death may serve as a locus for unresolved private pain. Richard Huntington and Peter Metcalfe argue that the death of a royal figure symbolizes the deaths of all the people. The state funeral is therefore a powerful container for public sentiment. It is also, at the same time, a potential tool for the ruling elite to establish or confirm their authority, as the death of a key figure may signal the transference of power. The state funeral thus negotiates both public and private realms and seeks to frame transitions within the staging of a ritual practice.

Funerals and Funeralization in Cross-Cultural Perspective

This entry deals with funerals and funeralization across the multitude of world cultures. Thus, a definition of funeral that is respectful of cross-cultural variation includes the death rituals engaged in to deal with a corpse plus all the rituals that deal with the spiritual, property, role changes, and other matters connected to the death. Death rituals are all the rites, ceremonies, celebrations, and other culturally recognized and commonly performed activities that are carried out as the result of a death. Funeralization is defined as the action, process, or result of carrying out a funeral.

One cannot understand what death means in a culture or how the survivors cope with the emotional, relationship, economic, spiritual, and other consequences of a death without understanding funerals in that culture. There are enormous variations in funerals from culture to culture, but there are also similarities. The variations and the similarities together illuminate human plasticity in dealing with death and also what is basically human.

The enormous differences across cultures in rituals surrounding death indicate that one should be careful in applying a conventional English language definition of the term *funeral* to death rituals across cultures. If one defines a funeral following conventional English language usage as the rituals engaged in shortly after a death to dispose of the dead body through burial, one would miss that in many cultures the rituals may be carried out over months or even years and that body disposal does not necessarily involve burial. Indeed, the death rituals of many cultures will seem foreign to those in the United States who are accustomed to conventional U.S. funerals. For example, in many cultures funerals can include ritualized wailing, self-mutilation, shaving the heads of bereaved individuals, investigating who performed the witchcraft that killed the deceased, animal sacrifice, ritual obscenity, destroying the property of the deceased, or fleeing from the corpse. What might seem bizarre makes sense once one understands the relevant cultural meanings. Within the meaning systems of a culture, how people deal with a death makes sense to them and is valued by them.

All known cultures have funeral rituals, practices that are preferred, that are typically engaged in, that have meaning and give meaning. Bodies are not just abandoned. A death must be dealt with. And this says something about our common humanity. Death is not trivial. Corpses are dealt with in meaningful ways. Funeral rituals give

meaning to the life and death of the deceased, to life and death in general, and to the reactions of the survivors. Funeral rituals are social events and so they define social relationships, enact and reinforce social norms, and often strengthen social relationships.

In many cultures, funeral rituals are spread over months or years, with an initial set of rituals and an initial disposal of the remains of the deceased shortly after the death. Eventually there is a final funeral ceremony, months or years after the death, which usually ends formal mourning, and often at the final ceremony there is a final disposal of the remains of the deceased.

Social Science and Indigenous Understandings of Funerals

There are many social science theories that explain and illuminate funerals. These theories can help us to understand, for example, why it is that people in some cultures destroy the personal property of the deceased or carry out funeral rituals that extend over several years. Looking at a culture from the outside may point to underlying processes, connections among different aspects of the culture, and lines of thought that make sensible and relatively simple what otherwise would be, for the outsider, a disconnected hodgepodge.

Social science explanations are often, however, out of touch with the cultural realities of the people engaging in their culturally meaningful funeral rituals. People are likely to have their own cultural reasons and explanations for what is going on and what they do. To ignore these because one is relying on a social science rooted in one's own culture for understanding could be seen as ethnocentric or culturally rude, and it also may rob one of genuine understanding of relevant realities of the people in that other culture. For example, one may use social science theories to look at a culture's death rituals as involving rites of passage from one set of statuses and roles to another, as involving breaking ties with the deceased or recruiting grief support, or as giving meaning to the death and the life of the deceased and to people's feelings of grief. But the realities of people in that culture may concern respecting and caring for the spirit of the deceased, healing a breach in kingroup connections, and carrying out proper kinship obligations. Thus, genuine cultural sensitivity requires one to understand that social science theories typically come from an outsider's culture and that to understand the experiences and realities of the people from a culture in their own terms, one must grasp the meanings they give to events.

Cultures Are Internally Diverse

It is a mistake to assume that people who share cultural origins carry out death rituals in the same way. Death rituals in any culture are likely to be diverse, depending on the status, age, and gender of the deceased, the apparent cause of death, the wealth of the family and community of the deceased, the religion of the deceased and of the closest survivors, the occupation of the deceased, and much more. Such variations make sense in the meaning system of a culture that has the variations. But many cultures are also divided into subcultures, and the funeral rituals and meanings given to these rituals may be quite different from one subculture to another. The subcultures may exist because different populations in the society have different cultural origins, have had different contact with other cultures, have different religions, or have responded differently to a national government that tried to impose new cultural practices and meanings. The products of this cultural complexity are, in some families and communities, cultural practices and meanings that blend several cultures but also are uniquely different from what is in any of the cultures from which the practices and meanings are drawn. The product could be that at funeral rituals there are tensions among family members about what is proper or that different groups in a community observe somewhat or even radically different rituals.

Not infrequently, a culture's complexity and diversity concerning funeral rituals are played out during the funeral rituals. In a sense, in some cultures part of the funeral rituals is contention or what should be done. And the contention also then shows up in judgments made by participants and onlookers who hold different cultural standards regarding the funeral rituals. They may, for example, differ on how much attention, support, and resources should be given to a bereaved spouse and how much should be given to the extended family or the community. They may differ in how to

protect survivors from the wrath of the spirit of the deceased, or whether such wrath is a possibility. They may differ in whether the fate of the spirit of the deceased is at stake and, if so, how best to help that spirit to a good future. These are not abstract and academic issues but often issues of enormous importance and emotionally intense feelings. But then it is also possible that people will come to accept their differences and even hold one another to different standards depending on the cultural allegiances of the deceased or of those who are most bereaved.

Cultural Diversity Within the United States

Often people who write about funerals in the United States write as though there is a single culture or, at most, a few cultures in the country. But the reality is that to understand funeral rituals in the United States, one must be open to the enormous variation among the several thousand different cultures present there.

Many people in the United States ignore the cultural diversity in death rituals around them. They may be intolerant and insensitive in ways that make it difficult for people from a variety of cultures to carry out their rituals. In fact, local laws may even block people from doing what they feel they must do to deal properly with a death. For example, Ann Fadiman reported that some Hmong immigrants from Southeast Asia who carried out funerals that included loud chanting for several days and also animal sacrifice found that local U.S. laws blocked them from engaging in their rituals. Laws that block funeral rituals can create dire personal, family, and spiritual problems for the bereaved, the community, and the spirit of the deceased.

Another problem that can arise from U.S. diversity in funeral rituals stems from the fact that some couples and families are bicultural or multicultural. People in such couples and families may get along in many ways, but their differences may come to the fore when someone dies. Culturally based funeral rituals are often difficult to compromise, because they are linked to very strong feelings and may have intensely important meanings concerning such matters as the fate of the soul of the deceased, the spiritual well-being of the survivors, and the family's place in a cultural community. Particularly the first times a bicultural or multicultural couple or family must carry out funerals might be especially challenging. For example, there are difficulties in some couples in which one partner is Jewish and the other is not. Many observant Jews believe strongly in not carrying out an autopsy, not embalming, and burying the deceased on the day of the death. A non-Jewish partner might believe, along with a large number of people in the United States, that an autopsy will help in coping with the death by providing understanding of what happened and that it is desirable that the body be embalmed and the funeral delayed a few days until out of town relatives can come.

When Appropriate Death Rituals Cannot Be Performed

Sometimes people are blocked from carrying out culturally proper death rituals because of war, natural disaster, or the nature of the death. It may not be safe to carry out the rituals, the body (or the entire body) may not have been found, or the ingredients or personnel for the proper rituals might be unavailable. Sometimes it is not known whether a person has died. Failure to carry out the appropriate rituals can add to the burden of grief, can block moving forward with some sort of closure, and may have dire cultural meanings, for example, that the soul of the deceased cannot go to heaven or that the spirit of the deceased will torment the living. To illustrate, in Rwanda in the 1990s, hundreds of thousands of Tutsi people were murdered in a wave of genocidal violence. As Deogratias Bagilishya wrote, the deaths of so many people who might have carried out death rituals for others who were killed, and the flight of many of the survivors, meant that death rituals were typically not carried out. In Tutsi beliefs, this means that great misfortune will occur to surviving family members. So in addition to the burdens of grieving many deaths, mass murder, and the loss of a way of life, Tutsis also have to contend with fear of possible consequences of not carrying out the proper death rituals.

Economics of Funerals Cross-Culturally

Across cultures, death rituals are often relatively costly. They may, for example, involve high costs for feeding visitors, paying ritual specialists,

providing proper clothing for the deceased and certain mourners, giving up income during an extended mourning period, or destroying the house in which the deceased died. Sometimes people cannot afford the proper rituals. For example, Paul C. Rosenblatt and Busisiwe Nkosi reported that among South African Zulus, many of whom are impoverished, widows are typically required to carry out a funeral ritual and a year-long *ukuzila* mourning ritual, and carrying out these rituals properly involves substantial expense. But many widows are very poor, and their neighbors, in-laws, and others in their social world may be just as poor, with nobody having enough to eat or proper housing, let alone money to support the expenses of funeral rituals. So the rituals may be carried out but not at the most desirable level, and the grief of some widows is complicated by their feelings about their poverty as well as by their feelings concerning their husband's death.

Funeral Rituals Change

Much can happen to change funeral rituals in a culture. In fact, it is difficult to find a culture of which one can say that the funeral rituals have been the same for generations. People immigrate to other parts of the world and lack the cultural supports to carry out the rituals that used to be carried out. Cultures change, for example, in gender roles, ideas of health and illness, religious beliefs, technology, residence patterns, and economics. People may intermarry with those of other cultures. A great epidemic like that of HIV/AIDS produces so many deaths that many who would have carried out the traditional rituals are gone and the financial and time resources for carrying out the rituals are not available. The changes do not come easily. Some people resist them. Some who enact the changes do not feel good about what they are doing. They may, for example, fear bad luck, feel guilty, or fear for the soul of the deceased. The changes may be seen as temporary or the best they can do given the circumstances, but even in those cases the changes will make great difficulty for people.

It was less than a century ago that bereaved people in many cultures in the United States stopped wearing mourning clothing and stopped observing a formal mourning period. The reduction in funeral rituals and public observance of mourning freed many people from heavy expense, from engaging in activities that did not fit how they felt, and from limiting what was proper for them to do at the workplace or in the community and family. But the de-ritualization of society's approach to dealing with death left some bereaved people at sea about what to, lacking in community and family support, and not helped along the path by funeral rituals that drew them through the grieving process and offered answers to important questions arising from the death.

Funeralization Outside the United States

In many cultures there is nothing like a funeral industry. Families and communities are on their own in funeralization, in carrying out their own death rituals. But in a number of societies, funeral industries have developed. In many of those societies, commercialized funerals are carried out only for some deaths. For example, reflecting wealth differences in other areas of society, the families who have commercial funerals are usually relatively well off.

The differences between U.S. funeral industries and funeral industries in other societies are instructive. For example, Hikaru Suzuki described how funeralization in Japan has, in the past half century, become increasingly commercialized. The shift to commercial rituals marks a shift away from fear of death and malevolent spirits, fear of decomposing remains, the need to move the spirit of the dead to the other world, and the need to strengthen internal family ties and also the family's ties with the community. With commercial rituals, there is little concern about impurity of the body and there is less sense of community connection. Now families focus on paying funeral specialists rather than on issues of danger and relationship. Whereas the community and family funerals of the past reinforced cultural values concerning social relationships and spiritual matters, contemporary funerals reinforce cultural values concerning economic transactions and reliance on paid experts. Commercial funerals in Japan are still culturally quite Japanese. For example, during the funeral service the corpse is treated as a living body, most bodies are subsequently cremated, and after that there is a 7-day memorial service. But the shift to commercial funerals still has brought substantial change.

In modern Hong Kong, to take another example, much of the traditional sequence of rituals and many of the traditional mourning practices have been curtailed, and there are more or less commercialized processes available to lead families through their funeral rituals. But that does not mean that Hong Kong funeral rituals are much like commercial funeral rituals common in the United States. Daoist, Buddhist, Confucian, or even Chinese Christian funerals still have central Chinese cultural elements and meanings. Commercialization brings common elements to funerals around the world, but it does not erase the very substantial variations across cultures.

Funerals and Funeralization in Major Religious Traditions

A funeral is a service marking a person's death. It is highly idiosyncratic, involving diverse customs, social statuses, beliefs, and practices used by religions or cultures to remember the dead. Funerals, derived from the Latin *funus*, are social and commercial events. Funerals involve an array of services as part of the process of paying final tribute to the dead.

Funeralization involves planning, implementing, and directing a funeral and burial according to the social, psychological, and religious needs of the deceased. The last step of funeralization is monument selection. Rituals, customs, prayers, eulogies, and often elaborate grave markers are employed to honor the dead. Historically, final tributes to the dead are found at ancient Neanderthal gravesites in France, India's mausoleum the Taj Mahal (an emperor's 1648 grief-stricken tribute to his dead wife), and Italy's famous 1469 relic of Saint Catherine's head preserved on a marble altar at the Chapel of Saint Catherine of Siena.

Along with industrialization, the increasing secularization and commercialization have changed the funeralization process. In America, this change evolved from simple burials to elaborate commercialization of death involving mummification, high-cost casket and vault display rooms, and a variety of buying options. Being funeralized is important in black American culture, with poor families spending more time and money than other ethnic groups on the dead. Throughout history there have been significant changes in funeralization leading to interesting and diverse practices.

Bahá'í Funerals

The Bahá'í faith is the newest world religion. A Bahá'í is a follower of the 19th-century "Manifestation of God" named Bahá'u'lláh, whose writings outline the Bahá'í teachings on death, burial, and afterlife. Known for its simplicity and dignity, the Bahá'í faith avoids funeral customs and rituals associated with older religions. Elected local spiritual assemblies (nine people) assist families with weddings, funerals, and other community

business. Bahá'u'lláh said death is a joyous event, a gateway to an afterlife. Heaven and hell are conceptualized as spiritual conditions, a continuum of varying degrees of closeness (heaven) and remoteness (hell) to God.

The deceased should be wrapped in five silk or cotton sheets; a single sheet of either fabric is sufficient for those from less affluent families. A Bahá'í burial kit contains 9 yards of very soft fabric (e.g., 100% natural silk or 100% pure cotton) cut into five pieces, the Bahá'í burial and the Bahá'í funeral service booklet, a small bottle of rose water, and a Bahá'í burial ring (with the inscription "I came forth from God and return unto Him, detached from all save Him, holding fast to His name, the Merciful, the Compassionate") placed on the deceased's finger.

The Bahá'í faith tries to avoid commercialized and materialistic funerals or memorial services. First, the burial ring is placed upon the dead person's body, which should not be transported more than 1 hour's journey from the place of death. Second, cremation or embalming is not permitted. Bodies should be treated with dignity and buried simply or donated to science. Third, funerals are absent of rituals or clergy, and typically are simple events. Funerals consist of the reading of prayers and other material pertaining to death and the afterlife from Bahá'í scripture. Services involve singing, music, and a eulogy. The only requirement is that the "Prayer for the Dead" (revealed by Bahá'u'lláh) be read by one believer. Prayers and readings are usually said at gravesite services. Bahá'í grave markers have nine-pointed stars or rosettes (the number nine is associated in the Arabic language with the name Bahá'u'lláh) with the word Bahá'í in the center and all other wording as desired.

Buddhist Funerals

Buddha's life, miracles, and death parallels those of Jesus. His "last supper" was an unintentional food poisoning by a blacksmith. Although Buddha knew of the mushroom, he suffered unperturbed as an example to all. When He wanted water from a nearby muddy stream, the water miraculously became instantly clear. He instructed a disciple to take refuge in the "Triple Gems" of wisdom, by saying: "I take refuge in Buddha," "I take refuge in His teachings," and "I take refuge in the Buddhist community." He advised a disciple to tell the blacksmith not to feel remorse and that there were two important meals: the one before Enlightenment and the one before Death. Buddha told his last disciple to work diligently for spiritual liberation in the material world. When Buddha died, His body was cremated, following the Indian custom.

Although Buddhist funerals vary depending upon the culture, there usually is a protocol surrounding funeralization. While the social status and resources of the family of the deceased have a bearing on the final arrangements, rigid protocols dictate funeralization. Wakes last several days with an open casket and an altar *butsudan* set up with flowers, fruits, a bowl of water, incense, and a candle. Buddhists chant for an hour or so prior to services. Then a procession of significant others line up on both sides of the room and place a pinch of the ashes into a bowl as each person offers a prayer for the dead person. After all view the deceased, the priest signals with a gong for the funeral to begin. After prayers, the priest and others offer eulogies. The service ends with a family member offering acknowledgments to attendees. Following tradition, the majority of services are cremations.

The funeral is usually held on the day after the wake. The body is transferred to a temple and placed before the altar. Modern Buddhist funerals are diverse, but the services tend to be highly symbolic, ritualistic, culture specific, and elaborate. However, the chanting and priest offering, originating in Japan, remain unchanged.

Japanese families go to the crematorium and are given a set of chopsticks to pick up the bones. Two relatives, holding the same bone fragment together and putting it into the urn together, place the important Adam's apple.

Often Japanese will place some bones in a temple, while others go in the family grave. The urn may be taken home or to the cemetery and kept there until after the 49th day memorial service. There are large differences in knick-knacks, floral arrangements, and the processions depending upon localities. After the cremation and bringing the urn home or placing it in the grave (Japanese family graves have a hollow space inside the gravestone to put the urns of the family), there are memorial services as well as prescribed times for gravesite

visitations. After the 49th day service, the 1st year Festival of the Dead service is often considered important, and memorial services are held in the 1st, 3rd, 5th, 7th, and 13th years and in other years, depending on the sect, up to the 50th year.

Christian Funerals

Unlike most Protestant funerals, Catholic funerals are elaborate rituals. Typically, Catholic wakes are held at the funeral home. People pay their respects to the deceased, offer private prayers, and participate in a short service with a rosary being said. Funeral practices vary across different cultures but tend to be ritualistic. The funeral "Mass of Resurrection" with the priest wearing white vestments has replaced the former "Mass for the Dead" with black vestments. Jesus's resurrection is recalled in the eulogy segment of the Mass as an example of hope for the deceased. Depending upon the wishes of the deceased, the body may be disposed of in any dignified way from donating it to science, cremation, or burial. The priest usually sprinkles "holy water" on the casket both at the Mass and again when it's placed in the grave, where prayers are offered for the progress of the deceased in the afterlife.

Typically there are black and white Protestant churches in America, and these groups have vastly different rites and funeral services. In black churches, being "funeralized" is highly elaborate, costly, and lengthy compared to in white Protestant churches. Mourning and funeral customs of the black church illustrates the persistence of traditions despite modernization and changes occurring across all Christian groups. Within the black community, there is a wide array of burial rites specific to their West African heritage. The key characteristic is that over a week's duration all the relatives come to pay respects. Funeralization involves eating, socializing, and the sharing of emotions that are expressed over a prolonged period. Black families expect to embalm their loved one and bury him or her in a respectable casket. Typically pastors and services tend to be animated and emotional with varying degrees of "hallelujahs," "amens," and "praise the Lords" from devotees. Several soloists are scheduled for funeral programs, with special printed and elaborate programs with pictures of the deceased and family over a lifetime. After the service and the interment, fellowship is celebrated in the church so all can resolve their sorrows with comfort food.

White Protestant churches vary in ritual, but most families embalm the deceased and view of the body in the slumber room of the funeral home or the church prior to the funeral. Modern wakes often involve slide shows of the deceased. The day after the wake, the funeral service is held at the home, church, mausoleum, or cemetery. Lutheran and Episcopal churches hold ritualistic services, while Pentecostal and Baptist groups emphasize evangelism during the service. Baptists do not pray for the dead because they believe their eternal outcome is already determined at death. Generally Protestant services involve a eulogy followed by a procession to the cemetery where the primary group gathers with or without a pastor for a short graveside interment service.

Hindu Funerals

A Hindu is a follower of the Manifestation of God Krishna. Hindu funeral rites are called *Antyesi*. This sacramental process differs across ascribed status in society. When a loved one dies, family members offer water to the body. After that, the corpse is washed and dressed in clean clothes. If the deceased is a married woman who dies before her husband, she is dressed in red bridal finery. The rest are dressed in white or pale clothes accented with sandalwood paste and tulasi. According to Antyesi, the body must be cremated before dawn of the day following death but, with morgues now available, this procedure need not be rigidly adhered to; thus family members who live a distance away have time to travel to view the body.

The body is placed on a funeral bier made of bamboo that is carried by four male members of the family to the cremation grounds located near a body of water. The funeral byre is placed in a funeral hearse and transported to the crematorium where the body is placed in an incinerator. After cremation, the leftover ashes and bone fragments are placed in a pot and thrown into the water.

Death in the Hindu family starts a period of intense pollution for the family members for at least 11 days. Immediately after the cremation, participants bathe and change clothes before

returning to the deceased's house. The following days are spent in bereavement with family gathering around a picture of the deceased and the priest reciting scripture. An oil lamp is always kept lit in front of the deceased's picture. Each of these days a food offering (*pinda daan*) for the deceased is placed by an altar located outside the house in a public area. On the 10th day, a formal funeral is performed, which includes making offerings into a consecrated fire and offering sacred water to the deceased and to ancestors. This is also the day when the period of pollution ceases and people shave and wash their hair. The eldest son or whoever has lit the funeral pyre will shave his head. The 11th day, the family comes back to normal living and the occasion is celebrated with a feast to which the extended family and neighbors are invited.

Jewish Funerals

The Hebrew scriptures portray an intimate relationship between *Yahweh* (God) and His believers throughout the life cycle. The Torah says little about afterlife, however, so Judaism is focused on this world and helping the bereaved family. Life after death for many Jewish groups lies with the legacy of the deceased family; hence, death represents a tragedy. The Jewish funeralization process is modest and simple. Upon death, bodies are cleansed in the synagogue. Funerals are divided into two services. The first is held at the funeral home or synagogue and the second at the cemetery. Funerals are simple with the rabbi employing psalms and prayers of comfort and an appropriate eulogy. The rabbi reads the solemn "God full of compassion" prayer and *Kaddish* prayer at the conclusion. Early burial has always been practiced by Jewish people. With white shrouds covering the body, the deceased is placed into a simple wooden box. At the conclusion of graveside prayers, dirt is shoveled into the grave.

Family mourning is divided into three parts. Mourners must receive the comforters and remain in deep contemplation. Then there is a 30-day period after the death when the mourner is restricted from attending community events. The third is a 12-month period of mourning, with other ritualistic requirements and stipulations for families depending upon the denomination.

Islamic Funerals

Although it is a time of grief, death is a gateway to a better existence. When a Muslim dies, loved ones offer the dying person their love and reminders of God's mercy and forgiveness. A Muslim's last words are to be the declaration of faith: "I bear witness that there is no God but Allah." Upon death, the bereaved are encouraged to be calm, to cry but not wail. They should pray for the departed and begin funeralization. The eyes of the deceased should be closed and the body covered with a white sheet.

Muslims strive to bury the deceased as soon as possible after death, avoiding mummification or cremation. In preparing the body, family or community members wash and enshroud the body in sheets of white cloth. Martyrs are buried in their own clothes. The deceased is transported to a public area for funeral prayers instigated by an imam (clergy), joined by loved ones and community. The deceased is then transported to the cemetery for burial.

Although members of the community participate in funeral prayers, only males accompany the body to the cemetery. Muslims prefer to be buried in a Muslim cemetery located close to where they died. The corpse is laid in the grave with or without a coffin (as local laws permit) on his or her right side, facing Mecca. Muslims have simple gravesites without elaborate markers. Families observe a 3-day period of prayer, seeing friends and avoiding decorative ornamentation of self. In accordance with the Qur'an, widows observe an extended mourning period of approximately 4 months.

Zoroastrian Funerals

Zoroastrianism (1800–1500 B.C.E.) is an old religion. Followers of the Messenger Zoroaster, Zoroastrians believe in two forces. There is one universal, transcendent God (Ahura Mazda) and His angels versus the devil, who is aided by evil spirits. Before death, a Zoroastrian is to recite the prayer for repentance, followed by several other prayers. A lamp used as a symbol of a dispeller of evil is then lit and placed close to the dying person's head. Then pomegranate juice is consumed as a symbolic gesture of preparation for immortality.

When the person dies, a prayer vigil typically occurs, along with a chanting hymn, a repetition of confessional, and an invocation of the messenger divinity. The body is cleaned for rituals to follow either by corpse cleaners or family members of the same sex. Body preparation for burial include the deceased being dressed in white (the color representing "Mazda") clothes with hands placed across the chest and legs crossed, with face exposed. The body is laid on stone floors facing southward (the location of heaven). The number three—representing good thoughts, words, and deeds—is represented in the drawing of centric furrows around the body, with prayers recited, while oil lamps are lit to dispel evil. The funeral occurs within 24 hours, during daylight to keep evil pollution away. Two magi perform the rite of faith or service, after which the face of the deceased is covered and loved ones pay final respects prior to burial.

The bier is carried by loved ones, or the corpse is placed in a hearse that travels to the funeral site followed by a procession of relatives and friends. The historical "funeral tower," where Zoroastrian corpses were placed facing the East for quick decay or consumption by vultures, is what makes their funeralization unique. However, Middle Eastern and industrialized countries tend not to do this, so other options are employed like ground or wall burials. After the burial, relatives and friends bathe to avoid being polluted by evil spirits.

Gender and Death

All people die, men and women alike, but there are some interesting differences in how men and women approach death and dying. In the past, men and women had different experiences with the dying process. Historically men experienced death by seeking it out or confronting it in a predominantly male context. Men were more likely to be employed in hazardous occupations such as mining, to be engaged in military combat, or to pursue dangerous lifestyles. Women encountered death at home, by caring for seriously ill family members, preparing the dead, and comforting the bereaved.

Currently most Americans die in an institutional setting, with nearly one in five older adults dying in a nursing home, and many more die in a hospital than at home. Death in late life is often the result of a decision to halt futile or unwanted medical treatment after a period of chronic illness and dependency. Whereas the circumstances of death may be similar for men and women, the response to one's own terminal illness, socially constructed attitudes toward death, the experience of caring for dying people, and the response to loss, grief, and bereavement are likely to be quite different for men and women. This entry explores differences in life expectancy and primary causes of death between men and women, how gender might affect one's desire for a hastened death through suicide or physician-assisted suicide, and gender differences in grief and bereavement.

Life Expectancy

On average women live longer than men. Worldwide life expectancy for all people is 64.3 years; for males it is 62.7, and for females it is 66 years. Around the globe women live longer than men, except in 10 countries, including Pakistan and Bangladesh, in part due to female infanticide. The sex difference ranges from 4 to 6 years in North America and Europe to more than 13 years between men and women in Russia. Women's greater longevity means that elderly women are forced to live with death longer than men. Having faced the death of partners, peers, and family, women must then face their own death, often without the support of a spouse.

The decisive advantage females have in life expectancy is the result of excessive male mortality at all ages, beginning with fetal deaths. More males than females die during childhood, primarily due to infection, which suggests immune system differences. By early adolescence numerical parity is achieved, but in early adulthood more males than females die due to accidents and violence. Eighty-five percent of centenarians are women, but the men in that group are in better shape physically and cognitively. Gender differences in life expectancy disappear at age 105. Men who survive to age 105 represent the fittest of their sex and have outlived the disadvantages of being male.

The reasons for the difference in life expectancy between males and females are not fully understood. Women appear to outlive men due to both lifestyle and biological factors. Lifestyle factors

that disadvantage males include their greater likelihood of employment in hazardous occupations and the fact that men generally drive, smoke, and drink more than women do. Men are more often the victims of homicide and also have higher rates of suicide.

Some scholars argue that women are biologically superior to men. Shorter male life expectancy may be another manifestation of the general rule among all mammal species that larger individuals tend on average to have shorter lives. Women survive the worst conditions better than men and are better able to endure environmental hardships such as cold and famine. Women have less body mass on average than men, need less food to survive, and have twice the percentage of body fat and thus better insulation. Premenopausal women produce estrogen, which has a protective effect against heart disease and other chronic conditions. Menopause may also be a means of protecting older women from the risk of death through childbirth.

Women have two sets of X-linked genes, which may be protective. Men have an X and a Y chromosome, and many of the defective genes that cause diseases such as hemophilia and color blindness are on the X chromosome. Women can compensate for a defective X chromosome gene if the counterpart gene of their second X chromosome is functioning properly. Thus, women's second X chromosome may be a longevity factor in itself.

There have recently been modest declines in the life expectancy differential for men and women. Two new factors have been influential. Men's survival rates are increasing somewhat more rapidly than women's, probably reflecting a decrease in deaths from heart disease. Lung cancer rates are increasing faster for women, reflecting the greater numbers of women who began to smoke 30 or 40 years earlier.

Causes of Death

Heart disease and cancer are the leading causes of death for both men and women. Like differences in life expectancy, differences in causes of death reflect differences in biological and lifestyle factors. Unintentional injuries are the third leading cause of death for men, but only the sixth leading cause for women. Alzheimer's disease is more likely to be the cause of death for women than for men, perhaps as a result of longer life expectancy. Suicide is the eighth leading cause of death for men but does not make the top 10 causes of death for women.

Top causes of death for men in descending order are heart disease, cancer, unintentional injuries, cerebrovascular diseases (stroke), chronic lower respiratory diseases, diabetes, influenza and pneumonia, suicide, kidney disease, and Alzheimer's disease. Top causes of death for women in descending order are heart disease, cancer, cerebrovascular diseases (stroke), chronic lower respiratory diseases, Alzheimer's disease, unintentional injuries, diabetes, influenza and pneumonia, kidney disease, and septicemia.

Hastened Death: Suicide and Physician-Assisted Suicide

There is evidence that older women are disadvantaged in their treatment by the medical profession. The relative lack of medical research on aging and female biology significantly limits the quality of medical care available to older women, whose longer life expectancy places many at risk for experiencing prolonged frailty and chronic health problems. Women experience depression about twice as frequently as men and are at greater risk for inadequate pain management, both of which have been associated with a desire to die. Although there are reasons to suspect that gender may play an important role in increasing older women's vulnerability to hastening their deaths through suicide or physician-assisted suicide, this does not appear to be the case. Women are less likely than men to kill themselves or to ask a physician for a lethal prescription to help them die.

In the United States, suicide rates are highest among older adults, males, and Caucasians. Men are 3 times more likely than women to kill themselves. In the United States, white men over age 50 represent approximately 10% of the total population but constitute 28% of suicides. Men may give in to the stress of physical illness, loneliness, and depression. Male suicides after retirement may be precipitated by a reduction in a man's capacity to work, a lessening of his capacity to function independently, or by a diminution of his means of exercising control. These three precipitating factors may be more essential to the ways in which men, as opposed to women, organize their lives.

In the United States, physician-assisted suicide is legal only in Oregon and is defined as a patient asking a physician to prescribe a lethal dose of medication under certain conditions. Patients eligible for physician-assisted suicide have to have been diagnosed with a terminal illness or end-stage condition that is expected to cause their death within 6 months, must be free of depression or other mental illnesses, must be residents of Oregon, and must know about options for pain management and end-of-life care such as hospice or palliative care. Since the Death with Dignity Act was passed in Oregon in 1997, by 2007, the last year for which data are available, 292 patients have died under the terms of the law. Approximately equal numbers of men and women died after ingesting a lethal dose of medication: 54% men and 46% women. Thus, when clinical guidelines are in place, there are no apparent sex differences among those who chose to hasten their deaths through legal physician-assisted suicide.

In the 1990s, pathologist Jack Kevorkian assisted with the deaths of over 100 individuals in Michigan. His actions were illegal, and no clinical safeguards protected the patients who sought his assistance in ending their lives. In a careful study of 69 of these individuals for whom autopsy and medical records were available, 71% of those who died with Kevorkian's illegal assistance were women.

Grief and Bereavement

At the start of the 20th century, dealing with the dead and caring for the bereaved were considered women's tasks. Today death and bereavement are professional occupations, and death work shows gendered patterns. Paid professionals in the bereavement business tend to be women, and those who care for the corpse are almost always men.

Men and women may react to grief and bereavement in different ways. Men tend to work to resolve their grief. Women are more likely to feel that grief has be lived with rather than resolved. There is one especially female mode of experiencing death: death in pregnancy, from abortions, and during or after childbirth. The biological experience of pregnancy and childbirth combined with the social role of motherhood may make a mother's grief and bereavement different from that of the father. Bereaved mothers report not "getting over" the loss of a child, but instead describe a process of rebuilding their lives around that loss.

Women are more likely to outlive their husbands due to greater longevity. Widowers and widows are perceived differently, which is likely an extension of the double standard that also affects older men and women. Older men with graying hair and expanding waistlines may be seen as successful, but women with gray hair and extra pounds "have let themselves go." Similarly, widowers are seen as more desirable, and are rarer, than are widows. The taint of death that attaches to widows marks them as socially undesirable. When a woman's husband dies, she may be seen as an object of pity or someone to be avoided. Widows tend to be seen as either socially uninteresting or as predators who are after other women's spouses. The bereaved widow reminds others of their own or their partner's death. Many women refuse to join widow's organizations because they do not wish to be identified stigmatically as widows.

In sum, when death is encountered, it may be identical or a completely unique experience for each individual. However, differences in life expectancy, causes of death, desire for death, and experience with the deaths of others show interesting gendered patterns.

Genocide

Genocide is the attempt to eradicate a people due to their race, religion, ethnicity, or nationality, usually by means of mass slaughter. The Holocaust, in which the Nazis murdered about 6 million Jews along with millions of others, is probably the most widely known genocide of the 20th century. Although the Holocaust may be unique in other respects, it is not unique in its being a genocide. Over the 20th century and into the 21st century, genocide has occurred in Cambodia, Germany, Iraq, Turkey, and Rwanda, and intervention has been rare. Some of these acts of genocide were probably preventable, and great harm might have been averted had the international community taken swift, decisive action.

Definition, Use, and Differentiation of Categories

The word *genocide* is relatively new, originating in the mid-20th century, when it was created by a Polish-born lawyer, Raphael Lemkin, who needed a term describing acts aimed to destroy entire races or cultures. Lemkin created a word using the Greek term *genos,* denoting race or tribe, and *cide,* a derivative of the Latin *caedere* "to kill." At the end of World War II, as the extent of the crimes perpetrated by the Nazis during the Holocaust became clear, the international community was ready to declare genocide a crime. The General Assembly of the United Nations passed a resolution condemning genocide on December 11, 1946, and on December 9, 1948, it passed the Convention on the Prevention and Punishment of the Crime of Genocide, widely known as the Genocide Convention.

The Genocide Convention defines genocide as acts committed with the intent to destroy, in whole or in part, a national, ethnical, racial, or religious group. Included in such acts are killing members of the group, causing serious bodily or mental harm to them, inflicting conditions of life calculated to physically destroy the group, imposing measures intended to prevent births within the group, or forcibly transferring children of the group to another group.

Perpetrators of genocide rarely describe their actions using the terms employed in the Genocide Convention. Instead, they devise a coded language loaded with euphemisms. The Nazis used expressions such the famous "final solution" and other phrases such as "special treatment" or "evacuation" to designate systematic programs of murder conducted on a massive scale. "Ethnic cleansing" was widely employed to describe what took place during the genocide in the Balkans. Manipulation of language can obscure what is actually taking place and help perpetrators to mentally distance themselves from the moral implications of the atrocities they commit.

Persons affected by, or engaged in, genocide can be differentiated by category. These categories include perpetrators, victims, bystanders (which may include individuals, communities, nongovernmental organizations, nations, or the international community itself), and rescuers who come to the aid of those targeted by a genocidal regime. This list is not exhaustive and other categories can often be distinguished. For example, there may be individuals or groups engaged in resistance—a category frequently overlooked but deserving of recognition. Individuals sometimes fall within more than one of these classifications. The same individual may be a rescuer or resister and also a victim. More rarely, a perpetrator may also be a rescuer. The Nazis are paradigmatic perpetrators, yet a few party members acted as rescuers. Oskar Schindler is probably the best known of these, due to the popular film *Schindler's List*, but he was not the only party member to engage in rescue efforts.

Reasons, Motives, and Methods

There is no known single motive or reason for genocide. The Nazis were motivated primarily by concerns for racial purity. The Khmer Rouge, responsible for the genocide in Cambodia in the latter half of the 1970s, were intent on creating what they took to be an ideal communist society, and they eliminated anyone they believed might obstruct this project. The genocide perpetrated by the government of Turkey in 1915 against its Armenian population was apparently motivated by concerns for national security, as was Saddam Hussein's genocide directed against the Kurds of Iraq.

A common feature of genocide is the presence of a hated group, members of which are perceived or represented as a threat. The Nazis represented Jews as a threat to the purity of the Aryan race and as destroyers of German culture. They used already existing stereotypes provided by centuries of vilification of Jews by the Christian communities of Europe and transferred preexisting religious hatred to race, utilizing the then-popular views promulgated by the eugenics movement to lend the transfer a veneer of scientific credibility. The Khmer Rouge massacred Buddhists and Muslims because of the supposed incompatibility of religious commitment with communism. Buddhists and Muslims were believed to threaten the realization of the society the Khmer Rouge sought to establish. Saddam Hussein unleashed execution squads and gas attacks against the Kurds, a stateless people spread over Iraq, Iran, Syria, and Turkey, during the war between Iraq and Iran in the 1980s. He apparently believed that some of Iraq's Kurds had allied themselves with Iran, and set about systematically destroying the way of life of the Kurds of northern Iraq in order to reduce this supposed threat to national security. The government of Turkey, allied with Germany during World War I, suspected that some of Turkey's Armenians were aiding opposing powers. The Armenians were taken to pose a threat to national security, and their elimination was a way of resolving this issue.

The methods employed in the commission of genocide vary. The Nazis employed the most advanced technology available to construct death camps modeled on industrial production to obtain the most effective and efficient means of extermination. They also utilized cutting-edge data-processing technology to maintain records. Saddam Hussein used sophisticated chemical weapons against the Kurds. However, the Nazis and Saddam Hussein also employed less sophisticated methods, such as rounding people up and shooting them. Little in the way of advanced technology was used in Rwanda or Cambodia. Many victims in Rwanda were chopped to death with machetes or bludgeoned with clubs. The Khmer Rouge slaughtered many using workshop and agricultural tools, such as axes and hoes.

Genocide and War

Genocide is often initiated under the cover of war. The government of Turkey perpetrated genocide against Turkey's Armenian population during World War I. The Holocaust occurred during World War II. Saddam Hussein's genocide against the Kurds happened during the Iraq–Iran war. The Rwandan genocide, in which a Hutu-led government orchestrated the slaughter of about 800,000 people, mostly Tutsis, took place in the presence of a UN peacekeeping force dispatched to secure a cease-fire designed to end a civil war, which rekindled when the genocide commenced. The genocide in Darfur began when the Republic of Sudan was fighting insurgency in the south, which spread into the western portion of the country. With its military resources committed in the south, the government established, supported, and utilized unofficial militias in the western region, and these militia groups have been the primary perpetrators of genocide in Darfur.

The cover of war frequently obscures the beginning of genocide. It is expected that a great deal of killing will occur in war. Given the increase in the number of noncombatant casualties associated with modern warfare, the start of genocide may be difficult to distinguish from massive collateral damage. In the confusion and dislocation brought about by war, distinguishing perpetrators from victims is often difficult. War sometimes delays a response to genocide, because the top priority is usually ending or winning the war; intervening in genocide then becomes a secondary consideration.

Recognition of, and Response to, Genocide

Once genocide is identified, there is often reluctance to give it official recognition. Recognition

brings some expectation of action, and governments are sometimes reluctant to act. Conflict with established geopolitical commitments is one reason for inaction. During the cold war, political alignment and balance of power were of overriding concern to the world's major powers, and this influenced the treatment received by the Khmer Rouge subsequent to the discovery of its atrocities. The Vietnamese invasion of Cambodia in 1979 exposed the genocidal program of the Khmer Rouge. Vietnam was allied with the Soviet Union and was widely represented as an aggressor nation by powers aligned against the Soviet Union. These powers were reluctant to undermine the legitimacy of the Khmer Rouge on the grounds of its genocidal activities, because this would have the effect of justifying the Vietnamese invasion. In the case of Iraq, there is little doubt that economic interests related to oil and trade had an effect on the political stance taken toward Saddam Hussein's regime. Public outcry over the alleged use of weapons of mass destruction far exceeded condemnation of his genocidal activities. The oil flowing from the Republic of Sudan has probably retarded robust action by the international community to bring the genocide in Darfur to a halt. Another reason stems from the system of international relations and law issuing from the Treaty of Westphalia (1648), which is taken to establish the absolute sovereignty of national governments in the administration of their own territory and treatment of their own citizens. As long as genocide remains confined within the borders of regimes that perpetrate it, intervention is conceived as a violation of that state's sovereignty. With the exception of intervention by NATO forces in Kosovo in 1999, genocidal programs have met with little or no resistance from the world's major powers.

Future of Genocide

There are some bright spots on the horizon indicating that the means to future improvements in the early identification of, and response to, genocide are becoming increasingly available. Sophisticated satellite surveillance makes it less likely that genocide can go undetected for long, and Internet communication makes it harder for genocidal regimes to suppress information about their activities. The International Criminal Court, the first standing court empowered to try perpetrators, makes it less likely that those with genocidal ambitions can harbor realistic hopes of escaping punishment. The intervention by NATO into the "ethnic cleansing" in Kosovo indicates that the absolute sovereignty of states may be conditioned by egregious violations of human rights. The "Responsibility to Protect," known as R2P, was developed by the International Commission on Intervention and State Sovereignty in 2001 and adopted by the World Summit in 2005. It provides further grounds for intervening in the affairs of a state that perpetrates, permits, or cannot prevent massive human rights abuses. Although R2P has significant support, some argue that it permits too much infringement on state sovereignty. These are promising signs but are unlikely to have much effect unless the political will of governments to take action is strengthened. If economic and geopolitical interests continue to play determining roles in responding to genocide and intervention is stymied by concerns over violating the absolute sovereignty of states even when they perpetrate massive human rights abuses, improved communication technology and early detection may be of limited value to the prevention of genocide.

Ghost Dance

The Ghost Dance of 1890 was an American Indian religious movement that was based on the return of prosperity for Indian peoples in the face of the depressed conditions that existed on American Indian reservations. The movement featured the belief that good living and the peaceful accommodation to whites would bring about the resurrection of their dead relatives and a return of the old way of life. It is referred to as the "Ghost Dance" because of its relation to the spirits of the dead of the participants who were often seen during visions obtained during the dance. The Ghost Dance of 1890 is distinguished from an earlier, smaller, less successful movement known as the Ghost Dance of 1870.

Origins

In late 1888 on the Walker River Reservation in Nevada, a Northern Paiute American Indian named Wovoka (Jack Wilson) fell ill. During his illness he had a religious vision in which he was taken to the Spirit World. There he was given sacred instructions and a message for Indian people. They were to be good to one another and be at peace with the whites, they were to work hard, and they were to perform a dance for 5 straight days. If they followed these instructions, Wovoka prophesied, the world would be renewed, which included the return of the Indian dead.

The late 1800s is a time period that marks the end of the freedom for American Indians, especially those of the Great Plains. By 1890 these groups were either removed to reservations in Indian Territory (present-day Oklahoma) or were placed on reservations in the general vicinity of their earlier homelands. Their way of life, from the village-dwelling horticulturalists to the nomadic tipi-dwelling buffalo hunters, was forever altered. Every aspect of their cultures, from what they ate, to how they structured their families, to their religious perspectives on the world, soon came under attack by the U.S. government. A variety of policies were enacted with the intention of assimilating native peoples into the broader American culture.

Under this extreme pressure, native peoples turned to the supernatural for guidance and assistance, with few results. Word spread of the Paiute prophet Wovoka and his message of renewal, of the return of the dead, and of the return to earlier ways. Representatives from tribes came to visit Wovoka and listen to his message of hope and renewal. The Ghost Dance teachings and dance quickly spread to many other tribes. Tribes that participated in some form of the Ghost Dance movement included Arapaho, Arikara, Assiniboine, Caddo, Cheyenne, Gros Ventre, Iowa, Kiowa, Lakota, Mandan, Osage, Oto, Pawnee, Plains Apache, Ponca, Quapaw, Santee Dakota, Wichita, and Yanktonai Dakota.

Ghost Dance Forms

Wovoka's original Ghost Dance was derived from the Paiute round dance, a world renewal ceremony. Instructions given to him in his original vision provided the basic beliefs of the dance as well as the form of the dance. The Ghost Dance provided a mechanism for the return of the old ways, a time when the various peoples had control over their own lives and were free, and their way of life worked for them and made sense. The dance was a simple round dance, a circling of dancers in a clockwise direction to music for hours at a time. During the dream-like state induced through repetitive dance, participants would visit their deceased relatives in the land of the dead. In these visions they would see their relatives living the old way of life and where game was bountiful. Dancers wore shirts and dresses that were created specifically for the Ghost Dance, which were decorated with symbols seen in their visions.

As the Ghost Dance spread and was adopted by new tribes, it was variously adapted to local beliefs and dance rituals. Groups added elements of their own rituals, such as a center tree or pole, which some employed in their sun dances. Others added preparatory rituals such as the sweat lodge or other dances. Symbolic elements from tribal religious beliefs were often incorporated as well. These various groups made the Ghost Dance relevant to themselves through these changes. Also, new aspects, particularly songs, were continuously added through visions obtained while dancing.

Ghost Dance Among the Lakota

The Ghost Dance is perhaps best known among the Lakota or Sioux Indians of South Dakota. The

Lakota adopted the Ghost Dance and infused it with aspects of their own culture. In addition to believing that there would be a return to the old ways by supernatural intervention, the Lakota form included Ghost Dance shirts that were believed to repel bullets. This new addition alarmed officials and local settlers and created a high level of fear. This culminated in the massacre at Wounded Knee, South Dakota, where American soldiers intercepted a band of Ghost Dancers led by Chief Bigfoot. The soldiers subsequently massacred more than 150 men, women, and children.

Ghost Dance Beyond 1890

The tragedy of Wounded Knee, along with the failure of the dead to return among other tribes, led to the eventual end of the Ghost Dance for most groups. However, several Ghost Dance leaders continued to preach the Ghost Dance beliefs after 1890. Several tribes on the southern plains continued to perform the Ghost Dance into the 1910s. It eventually spread northward into Saskatchewan, where it persisted in a derivative form known as "new tidings" until the 1950s.

Ghost Month

The annual reunion of the dead and the living, known as Ghost Month or Hungry Ghost Month, is the most important Chinese festival of the dead. Daoists (also known as Taoists), Buddhists, and Chinese folk religion believers observe it. During Ghost Month, an annual month-long furlough from Hades is given to all of its inhabitants. During this period, the spirits of all the dead return to earthly existence to visit their families and others. Ghost Month is observed during the entire seventh lunar month, and it is observed in its purest form in Taiwan. During this festival, activities include the preparation of elaborate food offerings, decorating temples with lights and lanterns to guide the spirits, offering prayers for the dead, and the burning of ghost money. Insight into Chinese eschatology is helpful to grasp the significance of Ghost Month. This entry describes Chinese eschatology and the polytheistic elements of Chinese culture, the activities that take place during the observance of Hungry Ghost Month, and its cultural significance.

Chinese Eschatology

In Chinese culture death is not the final annihilation of self but an alternate, spiritual form of existence. Upon death, the soul of an individual undertakes a 7-week journey traveling through the *yin* world, the otherworld. In this journey the deceased pass through various gates and courts where trials are held and judgments made regarding the deceased's conduct in life on earth. Ultimately the soul reaches Hades, the abode of the dead, and lives under the rule of the *Giam-lo-ong* (Mandarin: *Yen-lo-wang*), the main deity of the underworld.

Chinese eschatology posits an existence after death, but the Chinese concept of life after death portrays an existence not unlike earthly life. The existence of the dead in Hades has an economic counterpart in the world of the living in that it costs money, because it is believed the dead in Hades have needs. The dead need food and drink, housing, clothing, and all the other necessities that are required during life. These things must be supplied by the living, and it falls to the offspring of the deceased to assume this responsibility. The living care for the dead, and the dead are thought to take care of the living through their spiritual influence.

A Host of Ghosts

Within Chinese eschatology is the belief that when one dies, the spirit goes to Hades and will enjoy, if well provided for, an existence essentially the same as when alive on earth. Family survivors think of

the dead as viable entities who are only living in a different place. All disembodied spirits are known as *leng*, of which there are three categories: (1) recently deceased parents or relatives and long-deceased ancestors, (2) ghosts who have no living relatives to worship them and care for their otherworldly needs, and (3) gods. Gods are considered to be in the same generic category as ghosts and ancestral spirits because some gods are assumed to have once been mortals who led virtuous lives and became deities after death.

Chinese culture accommodates polytheism, and many Chinese worship multiple deities. Religious worship can be quite varied and may include Daoism (also known as Taoism), Buddhism, Confucianism, plus numerous folk and local patron gods, sea gods, and animistic deities. It has been estimated that there are in excess of 250 gods or deities that are worshipped.

Recently Deceased Parents and Relatives and Ancestors

The dead are believed to be aware of the living and, ideally, they guard the health and good fortunes of the surviving family members. Family members exert considerable effort to honor the spirits of their deceased kin and ancestors, especially parents, as well as the pantheon of gods, and they are particularly anxious not to incur the displeasure of either deceased relatives or gods.

Because the visiting dead are expected to feast, food and wine are offered to them. In addition to the food offerings, there are requirements for the burning of ghost money for gods, ancestors, and ghosts. There are numerous kinds of ghost money, which may vary somewhat from area to area.

The Uncared For

The second category of deceased spirits, the uncared for, are potentially harmful. It is this category of spirit that can be appropriately termed ghosts, or *kui*. The uncared-for spirits are called *hungry ghosts,* because having no living descendants, they have no one to supply them with food, drink, or money in Hades and are, thus, deprived, or hungry. Such ghosts may be malicious or at least mischievous and are likely to cause trouble, teasing humans or, in some cases, causing them harm. If the hungry ghosts are displeased, they can be particularly malevolent, bringing misfortune or disaster on the living.

The Observance of Hungry Ghost Month

At the break of dawn on the first day of the seventh lunar month, the gates of Hades are opened and the spirits are free to visit earth and roam about during their furlough from hell. Such spirits are of two varieties: the cared-for and the uncared-for ghosts. The cared-for spirits are those deceased individuals who have living descendants and relatives who make offerings of food and drink to them and send (burn) gifts of paper money, thus providing for their needs. Those with family ties are generally good-natured and spend their time partaking in the simple earthly pleasures of eating and drinking. The visiting spirits are supervised by *Tai-sai-ia* (Mandarin: *Ta-shih-yeh*), the deity who represents the underworld.

Special attention is given to the hungry ghosts. During this time, tables are set up outside homes and places of business to hold the offerings of food and wine. The offerings are usually located outside home or businesses in the hope that these ghosts will not come into the houses or stores to cause trouble or harm. Also, it is believed that hungry ghosts will steal the offerings for deceased ancestors or otherwise interfere with the family paying the proper respect and providing offerings to the ancestors and gods; this potential trouble is another reason for keeping the ghosts outside the home. If the offering is for a single offending ghost who is causing family misfortune, the offering is placed on the ground outside the rear of the house.

The principle activities of Ghost Month involve the presentation of offerings and sacrifices to the dead. For deceased parents and ancestors, families place special offerings of food, wine, flowers, and cigarettes on the family altar, although entire meals are sometimes laid out on the dining table, complete with dinnerware and chopsticks, with empty seats provided for each of the deceased. Because the dead are treated as if alive, offerings for the visiting spirits include food, ghost money, and entertainment. Beyond these offerings, there are also Chinese operas and puppet shows performed on street stages to entertain the visiting spirits, ghosts, and the living.

Ghost Month comes to a climax on the 15th day, which is called *Chung Yuan Festival*. This is a Buddhist festival marking the end of the annual period of meditation and prayer training for monks and nuns. On this date, there are sacrificial feasts in the temples, and there are elaborate changing ceremonies for the dead conducted by Daoist and Buddhist priests. On the final day of the seventh lunar month, the spirits of the deceased are summoned home, and the gates of Hades are closed until the next year.

The Function of Ghost Month

The activities that take place are directed at remembering the dead, including them in the social fabric, as well as eliciting amity between the dead and the living. The observance of Hungry Ghost Month is intended to address the special needs of the deceased and to conform to the traditional obligations of the living. Such activities also are reciprocal in nature in that the living are motivated not only by love and respect for the dead, but also by the expectation of benevolence on the part of the dead. By engaging in such behavior, the living attempt to ensure some control over their own lives and to maintain a social bond with the dead. Through the observance of Hungry Ghost Month, the living can reduce their own anxiety of death through recognition that the deceased continue a worldly existence. Through regular interaction with the dead, the living are able to more effectively deal with death.

Ghost Month is a time of anxiety for many individuals because of the possible misfortune that might be visited upon the living by a hostile ghost. It is also a time of festivity. The observance of Ghost Month also allows the living to engage in an act of altruism in giving to the uncared-for ghosts and their ancestors. Some families lay out extra food offerings for a deceased ancestor who was known to be a gregarious host and entertainer in life; thus it is assumed guests will also visit during Ghost Month. Perhaps most importantly, the annual reenactment of visiting between the dead ancestors and hungry ghosts and the living reinforces the notion of the continuity of the family and the spiritual immortality of the individual. Inasmuch as the dead survive in the memories and ritualistic behavior of the living, death itself is less feared. Even the plight of the hungry ghosts serves as reinforcement for the fabric of social life, for the message is clear: To be cut off from the kinship system, with its support and the attendant reciprocal responsibilities and obligations is, indeed, a grim prospect.

Ghost Photography

Since the beginning of time, people have imagined ghosts to haunt the world. These creatures were thought to be either hindered in their transfer to the afterlife or reluctant to leave their loved ones like the restless spirit of Catherine in Emily's Brontë's epic novel *Wuthering Heights*. Ghosts were seen as troubled and eager to intervene in the affairs of the living. To the audience, their punishments and corrections of injustice defined moral guidelines.

Folk tales about ghosts found their way into novels, theater plays, and the illustrated press. In Renaissance times, people were excited to see visible ghosts evoked by the use of the camera obscura in combination with the effects of mirrors and smoke. The camera obscura, a darkroom that through a lens in the wall projected an image on the opposite wall, was a device used by astronomers and portrait painters. About 1600, the instrument was applied for entertainment purposes. The invention of the laterna magica, which projected glass slide images, is attributed to both the German

Athanasias Kircher and the Dutchman Christiaan Huygens. About 1800, moving lanterns created the eerie effect of ghosts approaching the audience. The German Paul Philidor de Philipsthal discovered the even more convincing back-projection display of ghosts, the "phantasmagoria," that was shown in Austria, England, and France.

The Belgium-born Étienne-Gaspard Robertson impelled the phantasmagoria to international success with "fantascope" ghost shows. In 1805, the Germans Schirmer and Scholl presented the "ergascopia," a camera obscura combined with mirrors. Whatever the technique, in this period lantern ghost shows were more than just entertainment, they were an enlightenment instrument to destroy superstition. It could be a risky business, however. A ghost show of the German entertainer Oehler in Mexico City in 1806 put him in prison for months, as he was suspected of diabolic magic.

The projection of ghosts by painted glass slides in a magic lantern was popular entertainment well into the 19th century. After 1839, the suggestive reality of the new medium of photography increased the persuasiveness of projected ghosts. Photographs documented living and deceased loved ones in family albums, picture frames, or medallions. Photographs of ghosts appeared, showing dead people as transparent, supernatural apparitions that were meant to convince people of either the existence or the nonexistence of ghosts. Furthermore, photos originated which, to the willing beholder, depicted real ghosts by coincidence. It is a genre of ghost photography that still is very popular today, as can be deduced from the numerous ghost photos on the Internet.

Photography, the production of images by means of light, was considered a medium perfectly equipped to depict ghosts. The alleged objectivity of photography contributed to its reputation as a reliable and scientific medium. Nevertheless, photography sometimes instigated feelings of superstition. To some, photography seemed as if it could take possession of one's shadow and spirit. In line with this reputation was the medium's fame as an instrument that documented death and afterlife.

Ghost photography had innocent origins in early photographic experimentation. Long exposure times turned people into vague, see-through figures. It was the inventor Sir David Brewster who understood that this quality could be used to create "ghosts." His stereoscopic device caused a sensation in 1857 with a series of colored ghost scenes. An American, William Mumbler, is credited as the first to have photographed a spirit. The success of his photo of a deceased cousin started his career as a spirit photographic medium in 1862. In England, the first examples of ghost photography appeared in 1872. A portrait of the famous medium Elizabeth Guppy and her husband depicted a third veiled person. Many examples of spirit photography soon followed. By the end of the 1800s, spirit photos became crude and hardly convincing, sometimes even comical. By about 1900, the public preferred the moving ghosts of early cinema.

Moving and Moralizing Ghosts

Motion picture photography, or film, emerged about 1895. Film would add a new dimension to ghost photography by opening up new ways of storytelling. In 19th-century photography, depending on the presenter's focus, the audience was to be convinced of either the reality or the absurdity of the existence of ghosts. In 20th- and 21st-century film, however, spirits appeared not only in fantasy films or horror movies but also in stories dealing with social and moral dilemmas.

Early cinematographers, who had often been magicians and magic lantern operators, introduced ghostly themes in the new medium. The Frenchman George Méliès produced short films like *The Vanishing Lady*, in which a woman transformed into a skeleton. The Lumière brothers were also involved in ghost movies. The English hypnotist and telepathist George Albert Smith included photography and motion pictures in his theater shows. In America, it was Thomas Edison who started producing films of ghostly antics. In the early 1930s, when Hollywood dominated the international film industry, the adoption of synchronous sound coincided with the implementation of rear screen projection.

When movie studios set up special effect departments, ghost movies became increasingly elaborate. Modern ghost movies consisted of horror films like *Poltergeist* and *The Others;* tragic love stories such as *What Dreams May Come* and *Meet Joe Black;* comedies such as *Ghost Busters* and *Ghost*; and adventure movies like *Pirates of the*

Caribbean and *Harry Potter.* On television, music clips like Michael Jackson's "Thriller" and shows like *Charmed* and *The Ghost Whisperer* were successful. Katherine Fowkes has analyzed convincingly the function of ghost movies as vehicles to address delicate issues. As in literature and popular culture, movie ghosts acted as mediators between the living and the dead, conveying messages of moral import. In contrast to the withered creatures of horror movies, in these films ghosts appear as complete and unwounded.

A striking example of a ghost film with an intended moral was the first major pacifist movie *J'Accuse* made by the French director Abel Gance in 1919 (1939), condemning the horror and absurdity of war. In *J'Accuse*, two men meet in the trenches. Although the one man has an affair with the wife of the other, they reconcile their differences. The movie's message is that if the two soldiers can make peace, so could politicians. The film is all the more impressive for its location on the World War I battlefields of France. Unforgettable is the final scene, in which dead soldiers rise from their graves, walk through the countryside, and demand accountability for their sufferings.

A comedy film, *The Canterville Ghost* (1944), addresses war differently. It presents a ghost that in life was Sir Simon of Canterville, who in the 1600s fled a duel and found refuge in the family castle. His ashamed father dooms him to be a ghost until one of his descendants performs a brave deed. Simon believes he may be saved by Cuffy Willams, an American kinsman stationed with a troop of soldiers at the castle in 1943. *The Canterville Ghost* was intended to improve the hostile relations between the British public and the American servicemen in the United Kingdom, who were regarded as "overpaid, oversexed, and over here."

A Matter of Life and Death, retitled *Stairway to Heaven* (1946), had the same purpose. The movie describes Royal Air Force pilot Peter Carter, who tries to escape a burning Lancaster bomber. He makes radio contact with June, an American radio operator based in England, and carries on a tender conversation with her before he jumps without a usable parachute. Peter doesn't die because of a mistake of Conductor 71, his guide from the "other world." Instead, Peter wakes up near June's base, and they meet and fall in love. Conductor 71 tries to convince Peter to accept his death, but Peter demands an appeal and so appears before a celestial court. June's friend, the late Doctor Reeves, pleads Peter's case arguing that Peter has fallen in love and now has an earthly commitment that takes precedence over the afterlife's claim on him. Reeves has June take the stand, while she is asleep in the "real world," to testify that she is prepared to give her life to save Peter. When she steps on the stairway to heaven (depicted by a moving escalator), it stops to give her back to Peter.

Ghosts as Emancipators

Ghost movies provided vehicles for staging fantasies of sexuality, illustrating ethnic problems in society, and changing gender roles. A movie like *Topper* (1937) allowed for the "sex-without-the-sex" genre to avoid censorship of the motion picture production code. Ghost fantasies were combined with "black" characters to express spirituality and soul. Music and supernaturalism became emblematic of racial expectations in culture at large. In Hollywood movies, the threat of the "other" was exaggerated in stories about miscegenation and ghetto-ridden crime. In some cases, the threat is diminished by representations of African Americans as musicians, performers, or as kind spiritual advisors. A film like *The Night of the Living Dead* (1968) opposes the supposed qualities of "white" people to the soulfulness of "black" culture.

The marginal place of nonwhites in society and the masochistic role of ghosts in films of the 1990s are combined in movies like *Ghost* (1990). Here, the murderer Willy is presented as male, Puerto Rican, and evil. Oda Mae's character is that of the stereotypical mammy helper with her comic antics. The one person able to access the supernatural is both black and a woman, meeting stereotypes in popular culture. The film *Heart Condition* (1990) refers even more directly to the relationship between the ghostly state and racial inequalities. Here, a racist cop receives the heart of an African American lawyer donor and inherits his ghost. As in the movie *Ghost Dad* (1990), the film contains jokes about the protagonist's manhood that are in line with racial stereotypes.

Fowkes stated that reasons for the prevalence of fantasy films can be found in sources of modern-day

stress such as changing race and gender hierarchies. In the United States, the aftermath of the wars in Korea and Vietnam, race riots, assassinations, and Watergate set the stage for a new sense of public reality in which male authority figures became vulnerable. In response, Hollywood cinema aimed to correct the gender imbalance through a reassertion of patriarchy.

After World War II, when women working in male-designated jobs were restricted to home and family life again, movies addressed changing gender roles. Here, the protagonists are ghostly helpers appearing as angels. *It's a Wonderful Life* (1946) presents George Bailey dealing with dilemmas of male ambition versus domesticity. He is saved by the angel Clarence. In *The Bishop's Wife* (1947) the angel Dudley intervenes in job and marriage trouble. The protagonist in *The Ghost and Mrs. Muir* (1947) mobilizes gender stereotypes also. This movie is about the romantic relationship between an independent widowed woman, Lucy, and a dead captain's ghost. The female character's striving for independence and emancipation is hindered by her relationship with the male ghost.

More recently, the effects of women's emancipation were dealt with in *The Sixth Sense* (1999). In *The Sixth Sense* a psychiatrist who cannot express himself emotionally aims to help a boy plagued by visions of dead people. This film, like *Ghost*, *Ghost Dad*, and *Truly, Madly, Deeply* (1991), focuses on the difficulty of communication between men and women and the distant husband or father in American families. These ghost films deal with stereotypical gender relationships, portraying men as obsessed by work, distant from their wives and children, and unable to express themselves. Typically, these films have happy endings, with a male ghost finally succeeding in articulating his feelings for the people he loves.

Ghosts

Though possibly nonexistent, ghosts play a role in the human experience of death. Ghost stories are popular in most cultures, giving a glimpse of what life after death might be like, if real. There are three major issues to consider with regard to ghosts: (1) There are no scientifically acceptable reasons for believing in the existence of ghosts. (2) There is a philosophical question concerning the possibility of ghosts, conceived as immaterial personal agents. (3) There are other humanistic and social-scientific perspectives on ghosts.

Scientific Status of Ghosts as Immaterial Agents

Ghosts are usually regarded as immaterial, incorporeal, spiritual beings—souls without bodies. They are spirits of people who have once lived, have died, and have come back to haunt those who survived them, especially people who were close to them when they were alive or who had a special place in their lives. Ghosts, for some reason, cannot find rest in their deaths. The ghost is an apparition of a deceased person, returning to places where that person lived and/or died. Typically, something must be done by the living—for example, revenge a murder or correct some other injustice—in order to get rid of the hauntings. A person whose restless soul appears as a ghost may have suffered a violent death or committed suicide. Ghosts are often claimed to haunt an old, creepy house, for instance, or other places where something terrible happened.

There is no reason, in today's scientific age, to believe that such beings as ghosts actually exist. Parapsychology ("psychical research"), the discipline investigating alleged paranormal phenomena, such as hauntings or poltergeist, has for more than a century sought scientific evidence for the reality of life after death, including the reality of ghosts, with little success. Psychical researchers' methods have failed to meet the rigorous standards of scientific experimentation. Hence, parapsychology hardly deserves the status of a serious academic discipline, although in the late 1800s and the early 1900s, leading psychologists and philosophers, not to talk about writers and other artists, were interested in it. Scientists and skeptics about the paranormal have vigorously challenged psychical researchers' claims to have discovered evidence for the reality of paranormal phenomena. Accordingly, while science cannot prove ghosts unreal, skepticism about them is the received view in the academic community. In addition, those who do believe in life after death for religious reasons (e.g., traditional Christians) also criticize parapsychological attempts to communicate with supposed ghosts and demons.

Philosophical Issue of the Possibility of Ghosts

Presumably, then, no rational thinker regards ghosts as really existing. The interesting philosophical issue is whether such (or any) incorporeal entities are so much as possible, that is, whether there even could be ghosts, and if so, in what sense. There seems to be no *logical* contradiction in the concept of a ghost (as in the concept of a round square). On the other hand, according to current science, ghosts are likely to be not just contingently nonexistent (like pink elephants) but physically (naturally) impossible, that is, their existence would contradict the laws of nature. Somewhat less clear is what philosophers may call the conceptual or metaphysical (im)possibility of ghosts. Also, one may ask whether ghosts can be persons and whether immaterial persons are possible.

The metaphysical (conceptual) possibility or impossibility of ghosts can be examined by comparing ghosts to other fictitious entities. What distinguishes ghosts from, say, vampires or zombies is that the latter are considered material agents, whereas ghosts are immaterial—minds, souls, or spirits without bodies. Alternatively, immateriality (incorporeality) can be required in a narrow definition of a ghost; in a broad sense of the term, all undead monsters, material or immaterial, could be described as ghosts.

There is no doubt about a vampire being classified as a person. Count Dracula, for instance, has (or would have, if he existed) many of the normal characteristics of a person. A zombie, on the contrary, is usually taken to lack mental life; it could hardly be a person. The interestingly problematic case is the ghost. In ghost stories, horror fiction, and popular culture generally, ghosts are regarded as personal: They are apparitions of individual people who have once lived, have died, and cannot find rest in death. A ghost is someone in particular—or the restless soul of someone in particular. Ghosts are also viewed as agents: They can move, walk through walls, touch and manipulate objects and people, and so forth.

However, while ghosts are not among the common objects of philosophical research, powerful philosophical arguments have been constructed to demonstrate the issue of agency. Seeking to demonstrate the impossibility of agency, Charles Taylor's transcendental argument for embodied agency goes beyond Immanuel Kant's criticisms (in the 1780s) of the fallacious attempts to rationally prove the existence of a substantial, immortal, personal soul. While Kant argued that nothing can be known about such a soul, Taylor—and the philosophers he relies on, Martin Heidegger and Maurice Merleau-Ponty—maintain that there can be no agency without bodily movements and orientation in space.

As one may argue for the metaphysical impossibility of ghosts, conceived as immaterial agents, one might more generally argue for the impossibility of any kind of incorporeal persons. If (potential) agency is required for personhood, and if the argument for the impossibility of disembodied agency is sound, then persons are embodied. If ghosts are immaterial agents maintaining their personhood after death, they might be impossible, necessarily nonexisting. There are innumerable metaphysically possible but nonactual worlds populated by vampires (though vampires are, presumably, also naturally impossible, as their existence would breach the laws of nature); there may be

none populated by ghosts. This argumentation may not demonstrate the impossibility of immaterial, disembodied agents objectively, from a third person point of view. Rather, it may work only subjectively from the first person point of view, showing that one could not coherently conceive of oneself as being a ghost, or any incorporeal agent (although one might, with some effort, conceive of oneself turning into a vampire). From the perspective of a person's own agency, that agency is necessarily embodied. Yet, many would claim that they can imagine turning into a ghost after death.

More generally, there are conceptual difficulties involved in the dualistic idea that the mind could be metaphysically separate from the body. On the other hand, ghosts are sometimes claimed to consist of a special kind of matter (ectoplasm), presumably scientifically unknown. If ghosts are material, after all, their impossibility cannot be demonstrated by the argument against disembodied agency. Nonetheless, the ethereal matter—vaguely materialized ectoplasm, or something else—that ghosts would then consist of requires explanation. Only highly unusual material beings, not recognized by science, can penetrate through walls, like ghosts are presumed to do. If ghosts were allowed to be material in this sense, it would, in principle, remain an open empirical issue whether there are any—whether, that is, science discovers such hitherto unknown matter.

Humanistic and Social-Scientific Perspectives on Ghosts

Apart from philosophical considerations, ghosts can be, and have been, approached from the perspectives of the different human sciences. Social scientists can inquire into the ways in which beliefs about ghosts arise and are spread and maintained in social and cultural groups. Statistics show that a significant number of people (even 20%–30% of the population) in advanced Western countries, such as the United States, believe in the existence of ghosts, although there is no scientific evidence for such beliefs. Why this is the case, and what kind of differences there are in the popularity of such beliefs in different social, religious, economic, or gender (or other) groups, can be studied in sociology and social psychology. The reasons why an individual believes in ghosts may, correspondingly, be examined by psychologists or psychotherapists. A therapist may be needed, if a person is seriously afraid of ghosts (or of becoming a ghost) in a way that disturbs his or her daily routines. Cultural anthropologists, in turn, may engage in comparative studies on the similarities and differences in beliefs in ghosts in cultural traditions and folklore. The formation and evolution of such beliefs in different cultures are also questions for historians of ideas.

The ways in which ghosts and hauntings, as rich cultural categories, structure experiences of time and temporality, especially the role played by memories of deceased people in experiences of places and objects as temporally "layered," provide ample material for cultural studies of various kinds, for example, cultural semiotics. Moreover, in theology and religious studies, one may examine the ways in which Christian and other religious orientations have faced popular beliefs in ghosts. Exorcising evil spirits (demons) is a traditional Catholic practice.

Ghost stories have been known from antiquity. While they have often been transmitted orally across generations, ghosts—like vampires and the other "undead"—have also been brought from folklore into "high" literature, especially gothic and romantic. For example, Henry James's novella, *The Turn of the Screw,* employs an impressive haunting motive. Especially in 19th-century Victorian literature, ghosts and haunting were an important theme; earlier, the apparition of Hamlet's father's ghost in Shakespeare's play is a classical case of a ghost on the scene. However, 20th-century modernist writing may also display ghost motives. Literary theorists can study not only the interpretation and aesthetic value of ghost stories and horror fiction generally, but also, in a more postmodernist or deconstructive vein, the ways in which the ghost-like presences or absences of the author or of various kinds of potential readers may haunt the structures of the text.

Horror has increasingly been recognized as an important aesthetic category. Ghosts are paradigmatic examples of supernaturally horrible things. Breaking the categorical divide between life and death, literary ghosts—again like the other "undead"—are aesthetically employed to evoke horror. Ghost stories question people's natural beliefs about the boundary between life and death, mixing these fundamental categories in an intellectually

challenging way. In addition to being horrible, ghosts may be depicted as unhappy creatures craving for rest, deserving sympathy and pity. Mostly, however, ghosts are met in popular fiction (say, Stephen King's novels) instead of serious literature. Above all, ghosts are, sometimes skillfully but often banally, pictured in movies. Stanley Kubrick's *The Shining*, based on a novel by King, is recognized as one of the more serious ghost movies made over the past few decades. Even popular depictions of ghosts in literature and film may, implicitly, raise philosophical questions, even if their artistic value is limited.

In addition to these examples drawn from Western culture, the concept of a ghost is important in Asian traditions in relation to the process of making the dead transform into benevolent ancestors. Especially in Chinese and Japanese cultures, it is widely believed that if the dead are not properly worshipped as ancestral spirits, they will haunt the living as ghosts.

The philosophical problem of how an immaterial ghost *could* be visible by living humans or harm (or help) them is usually left open in both literary and cinematic treatments of ghosts. Although ghosts are fictitious—even metaphysically impossible—stories and beliefs about them may have effects on people's lives. The conceptual category of a ghost is, then, an important one in structuring the human experience of mortality.

Gold Star Mothers

The term *Gold Star Mothers* refers to mothers who have had a child die in military service in time of war. The gold star comes from a service flag displayed by families of American service personnel to show the family had had a child in the Armed Forces of the United States. A blue star was displayed for each child serving in the military, but if the child died in military service, a gold star was sewn over the blue star, often showing a thin blue edge from the original star. From this group of women an organization was developed—American Gold Star Mothers, Inc.

Service Flags

Many countries pay special recognition to women whose children are in military service in time of war or military action. During World War I, families in the United States did this by means of a service flag. The flag was designed in 1917 by a captain in the U.S. Army, Robert L. Queissner, to honor his two sons who were serving in World War I. It was quickly adopted by the public and supported by government officials.

The service flag, also known as a service banner, consists of a white field with a red border, with a blue star for each family member on active duty. A gold star (often with a blue edge) represents a family member who died during military service, regardless of the cause of death. It is intended to give honor to any who died while in the military of the United States in time of war.

Because service flags have a gold star for each member who has died, the gold star and the term *gold star mother* was first applied to mothers

whose sons or daughters died in military service in World War I. The connection of the gold star symbol to mothers may have started because of the practice of a gold star being worn on a black mourning armband by a mother in memory of her deceased child. On May 28, 1918, almost a year after the first appearance of the service flags, President Woodrow Wilson approved a suggestion that women should wear on their left arm a black armband with a gold star for each member of the family who had lost his or her life for their country. The idea of displaying the gold star was considered to be a positive representation of the sacrifice made by those who had lost their lives for their country and the pride felt by family members regarding this supreme sacrifice.

The display of a service flag was officially authorized by the U.S. Department of Defense on December 1, 1967 (in Directive 1348.20). Congress approved a regulation that such a flag could be displayed by members of the immediate family. It could also be displayed by organizations such as churches, schools, colleges, fraternities, sororities, societies, and places of business with which the member of the U.S. Armed Forces was associated.

American Gold Star Mothers, Inc.

The service flag and its gold stars gave rise to a formal organization, American Gold Star Mothers, Inc., which was founded by Grace Darling Seibold. Her son, George, was an American fighter pilot in a Canadian unit of the Royal Flying Corps. He was reported missing in action in 1917. On Christmas Eve 1918, Mrs. Seibold learned of the death of her son when his personal effects were delivered to her home. Though grieving her son's death Mrs. Seibold dealt with her sorrow by working at Walter Reed Army Hospital helping injured servicemen. She not only worked to help the sick and injured, she also reached out to other bereaved mothers of deceased military personnel. She organized a group consisting solely of such mothers with the purpose of providing mutual comfort and to help provide personal care to hospitalized veterans confined in government institutions. The organization was named after the gold star on service flags that families hung in their windows in honor of a deceased serviceman or woman.

On June 4, 1928, 10 years after the death of her son, Mrs. Seibold and two dozen other mothers met in Washington, D.C., and established American Gold Star Mothers, Inc. This nondenominational, nonprofit, nonpolitical group was composed of women who had lost a son or daughter in World War I. Their organization has continued to grow because membership was opened to those bereaved mothers of subsequent wars, including World War II, the Korean conflict, Vietnam, the Gulf War, and the global War on Terror. The group's charter lists some of the organization's purposes, which include assisting patriotic work based on each member's dedication to the community, the state, and the nation; keeping alive the memory of those who died for their country in wars; assisting veterans and their dependents in working with the Department of Veterans Affairs; maintaining allegiance to the United States; and promoting peace and goodwill for the United States and other nations.

Gold Star Mothers are dedicated to turning the pain of their loss into a positive force to help others. These special women are annually recognized and honored in the United States. On September 14, 1940, President Franklin D. Roosevelt issued a proclamation designating the last Sunday in September as "Gold Star Mother's Day," a recognition that continues.

Good Death

The good death is a difficult concept that has proven difficult to ignore. Would the wrong kind of death expose us to vengeance from the deceased spirit? Is self-termination the worst or the best kind of death? Should the health care system be expected to foster a good death for the nonresponsive person whose organs will soon be donated? Still haunted by ancient fears and hopes, the 21st century is adding its own technology-infused puzzlements. Both then and now, visions of the good death reveal much about the societies in which they have been constructed. The profusion and confusion of ways in which good death has been conceived are sorted out in this entry.

Good Dying or Good Death?

Often good death actually refers to good dying. Emphasis is on how a life ends, not on what might come thereafter. This orientation is at the core of the hospice/palliative care movement. People have varying beliefs about death and afterlife, but relief from pain and other symptoms would be welcomed by everybody. "Death with dignity" soon became a catchphrase, though the issue was quality of life during the final passage. Blurring the distinction can lead to miscommunication, when one person is focused on end-of-life experiences, and another on the nature and meaning of death.

Sometimes death does mean death. Devout people have suffered intense deathbed anxiety at the prospect of being judged unworthy. The memento mori ("Remember, you must die!") tradition that flourished in Europe from the 13th through the 16th centuries made the moment of death the final exam that determined the fate of one's soul. The outcome was uncertain. God's mercy might redeem a sinner, but a person regarded as pious and upright might be consigned to eternal damnation. The God-fearing person therefore prepared for divine judgment throughout life. The judgment of the dead had also been prominent in the dynastic Egyptian belief system, among others. Good death was the guiding vision in societies that envisioned the radically different outcomes of a blessed or tormented afterlife.

The distinction between dying and death would seem to parallel "alive" and "dead," but the increased use of life support systems has raised questions with medical, ethical, legal, and economic implications. Is the person in a persistent vegetative state dying, already dead, or suspended somewhere in between? Should termination be regarded as a good death that ends a bad dying? Or is this person's status now beyond dying-and-death, alive-or-dead, and good-and-bad? And perhaps beyond our ability to comprehend?

Euthanasia is a term frequently invoked in such a context. It is, laden, however, with ambiguity and emotional connotations. Euthanasia originally referred to an easy passage from life. The term can also be translated optimistically as "happy" or "pleasant." A person could be comforted by loved ones, priests, medications, and music, for example. The comfort theme has continued to the present day, but it was not long before euthanasia had morphed into mercy killing. On battlefields ancient and modern, a wounded warrior would be found in a desperate situation: helpless, mutilated beyond survival. His eyes, if not his voice, would speak for him. The warrior who found him—friend or foe—would end his suffering with a decisive blow.

Euthanasia became a questionable and highly challenged concept when the Nazis killed thousands of their own citizens who were institutionalized for various disabilities. These people were not dying, nor were they wracked with suffering. Nevertheless, their murders were described as euthanasia. This twisted exercise in mass killing served as rehearsal for the Holocaust, with its millions of victims. Understandably, euthanasia became linked with Nazi brutality. Responsible organizations that advocated improved care for the dying found it necessary to drop the term *euthanasia* from their titles. As the hospice movement emerged, it would encounter opposition based on fear that its hidden purpose was to terminate lives. Today, palliative care is better understood and the term *euthanasia* has been somewhat rehabilitated by subsequent responsible use.

Good death, then, can refer either to the best possible passage for a terminally ill person, or what the soul encounters when it has journeyed to "the unknown territory," as a prince of Denmark once observed. Both meanings are considered here,

focused on the question: What version of the good death do we prefer?

Perspectives and Preferences

Preferences are closely related to perspectives. Consider several perspectives from which preferences can be developed:

- An individual whose life will soon come to its close
- An individual whose health is not impaired and does not face a life-threatening condition
- Family and friends of a terminally ill person
- Caregivers of, and service providers to, a terminally ill person
- Society at large

Theoretically, people operating from all of these perspectives might share the same vision of the good death. In practice, however, differences are plentiful. Consider the following sample of perspective–preference links.

Society at large advocates the death that affirms its core values. The individual's final moments complete an ideal performance of the cultural script. Thomas More's *Utopia* (1519) offered an imaginary commonwealth as rational, efficient, and humane as the actual realms of the time were chaotic, bumbling, and brutal. The good death in Utopia occurred after a long life of service to the commonwealth. State-of-the-art comfort care was provided to the end. Nevertheless, some terminally ill people lingered in helplessness and discomfort. The authorities would then recommend self- or assisted termination. Those who agreeably terminated their lives would spare themselves suffering at the same time that they enacted a model exit. By contrast, the worst death was that of a person who dared self-terminate without official approval. Self-termination was lauded or condemned, depending on its accord with commonwealth values. The best of the good deaths occurred when the whole extended family turned out to be massacred in battle. The reasoning was that soldiers fight more fiercely when their families are also in danger. The family's willingness to expose itself to bloody death affirmed the all-for-the-commonwealth spirit. It is not only in Utopia that society prizes deaths that are interpreted as heroic or altruistic: A life that had not previously drawn attention can be honored as heroic if its ending strengthens a dominant cultural value.

There are also traditions in which deathbed transformations are held in the highest esteem. The deaths of some Christian saints are part of this tradition, as are the permutations of mortal into deity in ancient cults. In a different way, Zen masters have been admired for their ability to compose poetry with virtually the last breath. In Western society, memorable last words can leave the impression of a good death. An exceptional occurrence at the time of death can be regarded as the good transcending and validating all that has gone before and become inspiration for those who follow.

Caregivers and service providers in technologically developed nations typically are trained professionals, often specialists. Their primary mission is to keep people alive and functional as long as possible. Within this context, it is difficult to conceive of a good death: A fatal outcome can be experienced by caregivers as their failure. Physicians themselves observe that they withdraw from contact with dying patients because they recognize the limits of medicine's ability to thwart death. The best death is the one with the least notice, the least disruption in routine, the least fuss. Among the professional staff there may be little communication and less expression of grief. There may also be an implicit link with a fear that has permeated many traditional societies: The living are at risk from those who were wrongly dead or inadequately prepared for their afterlife journey. To ward off this hidden fear, modern physicians typically may insist on "doing everything" for the life-threatened patient, even if these interventions were painful, disabling, and inherently futile. "We did everything we could" does not necessarily make a death good, but it reduces the physician's emotional burden.

The palliative care movement challenges this approach. Comfort care is the priority when terminal decline and death are inevitable. Memories of the patient and family's gratitude for quality time together replace the stigma of medical failure.

Family and friends often are stressed by the medical procedures and surroundings, as well as by staff communications that do not seem to recognize their needs or answer their questions. From a family's standpoint, the good death

usually includes a trusting relationship with the professional caregivers, along with the feeling that their presence is welcomed. The average period of terminal decline has lengthened in recent years, so families often experience tension between the hope that their loved one will continue to survive and their exhaustion and stress from witnessing the decline over an extended period of time. "I want her to live" and "I don't want her to suffer any more: It makes me suffer, too" can be coexisting feelings. The "good death" occurs at what is experienced as the right time by family members and after having had adequate opportunity to be with, and take leave of, their dying loved one.

Healthy individuals typically are clear about what would not be a good death for them. Being maintained in a persistent vegetative state has become the most aversive prospect as reports of such conditions proliferate. What might be called "healthy dying" is the consensus choice for the good death. It should be symptom-free. No pain. No dependency. No helplessness. Nevertheless, the good death is not defined entirely by absence of negatives. Many people hope for the opportunity to end their lives at home with the companionship of loved ones. Some good death images include idiosyncratic elements, for example, listening to a particular song or revealing a long-held secret. Others emphasize maintaining personal control: "I will make the decisions. I will decide when it's time to go." By contrast, some express the serene wish that "I will be at peace with God and myself. That's all that really matters."

Individuals whose lives will soon come to a close often are restricted to the small world of disabled bodies, limited space, and routines of daily care. There can be refreshing moments of escapist fantasy, but the terminally ill person's outlook usually accords with reality. Most often, their wishes for the final days of their lives are simple, direct, and realistic, as, for example, "I want to be useful—somehow, to somebody—as long as possible." "I want the last few days of my life to be like any other." "I want certain people to be with me." "I want to feel at peace." The good death is the death one can manage with depleting energy, the death in which one can continue to be the same person, still in contact with the people and values that have long been cherished.

Appropriate Death

At issue is whether the physician, the health care administrator, the clergyperson, the lawmaker, or the scientist decrees what type of death is best. Pioneering existential psychoanalyst Avery D. Weisman has suggested otherwise. The appropriate death is the one that a person would choose for him- or herself if given the chance. Families, friends, and caregivers are most helpful when they understand and respect the terminally ill person as an individual, instead of relying on their own preexisting opinions. This concept must contend with all the others identified here, but perhaps offers useful perspective.

Grave Robbing

Grave robbing refers to the desecration of graves in search of items of value. These items may be artifacts, objects, or human remains. Grave robbing stretches back to ancient times, and there are numerous examples of graves looted back into antiquity for the treasures that may have been deposited there. This entry focuses on the robbing of bodies from graves. It examines first the activities of the 18th- and 19th-century so-called body snatchers who were infamous for the theft of fresh corpses from their resting places. More controversially, the discussion then considers the removal of human remains from graves, as carried out by the archaeologists of that period.

The Essence of Grave Robbing

The use of the term *grave robbing* assumes a moral dimension to the removal of artifacts and bodies from graves and a collective condemnation of acts deemed, therefore, to be immoral. Yet, there is some debate and controversy surrounding acts that are considered to fall within the definition of "robbing" and those presumed to have a moral quality because they are conducted under the guise of modern science and of furthering knowledge. So, for example, archaeologists' removal of mummified bodies from the tombs of the ancient Egyptian pharaohs was generally perceived as an exciting enterprise that has furthered human knowledge about the nature of life and death in an ancient and sophisticated culture. Indeed, much of our knowledge and understanding of ancient and medieval cultures is based on artifacts found, throughout the centuries, in the tombs of the dead.

In contrast, the removal of whole, freshly buried corpses is roundly condemned as an immoral practice that desecrates graves and violates the people buried there. These acts were common in Western societies in the 18th and 19th centuries, particularly in the United Kingdom and the United States, when the body snatchers went in search of bodies that were to be sold to the expanding schools of anatomy and medicine. Although the bodies were to be used in the furtherance of science and medicine, the fact that they were taken without permission, sold for profit, and that their erstwhile owners were only recently dead, led to public moral outrage.

In this entry the work of the body snatchers, or "resurrectionists" as they became known, and also the more recent debates about the repatriation of remains collected by archaeologists are discussed.

The Body Snatchers

In the 19th century and still today, understandings of the nature of the self means that it is not possible to own a body and, therefore, dead bodies cannot be protected from theft under the law. Even though it is currently common practice for bereaved kin to be consulted on the method of disposal and to be asked for their permission to use body parts for organ transplantation, there is no legal requirement for this custom.

Although there were cases of bodies being robbed from graves prior to the 18th century, the proliferation of this practice in the late 18th and throughout the 19th century was largely a consequence of the quest for greater understanding of anatomy and the functioning of the human body, as well as of the nature of disease. Dissection had for centuries been viewed as a postmortem punishment for extreme crimes, and the bodies of executed murderers were the only ones legally available to the anatomy schools. The number of anatomy and medical schools in Western countries multiplied dramatically during this period, and this created an increased demand for cadavers that could not be met within the established provision of allowing them the bodies of executed felons. Other sources had to be found, and this led to a lucrative trade in the "snatching" (or robbing) of newly dead bodies from graves.

The theft of recently buried corpses was commonly considered abhorrent and the dissection of deceased loved ones horrifying, especially at a time when there remained a popular belief in the resurrection of the body—dissection by the anatomists and surgeons was assumed, therefore, to extinguish hopes of an afterlife.

Due to a paucity of legislation and the fact that there can be no legal ownership of a body, grave robbers could only be prosecuted for stealing objects from a grave and not for the theft of bodies. Although they were at risk of personal injury from the families of the deceased, to avoid criminal

prosecution the robbers would exhume the body, drag it out of the coffin and remove any items of jewelry or clothing (such as the shroud), placing these back in the grave before carrying the corpse to the dissecting room.

To protect the corpses of loved ones from the body snatchers, bereaved families would keep a night watch and to this end "watching huts" were erected in some churchyards to guard fresh graves. For those who could afford it, undertakers were able to provide fortified coffins and caskets, iron straps to hold the body securely, and iron railings to surround the grave.

The scandalous activities of the body snatchers were eventually to be curtailed by the introduction of legislation enacted as a consequence of a number of infamous incidents. In the United Kingdom the law was changed as a result of public outrage generated by the activities of William Burke and William Hare. Recognizing the lucrative nature of the sale of corpses to the medical schools, Burke and Hare decided to bypass the difficulties associated with removing fresh bodies from graves by murdering people in order to sell their corpses. The pair enticed people to the Edinburgh lodging house owned by Hare's wife and plied them with alcohol before asphyxiating them and selling their bodies to Dr. Knox at the Edinburgh School of Anatomy. They were finally caught and, in 1829, tried for murder after having dispatched 16 people in this manner.

In the United States, grave robbing was considered revolting by the general public, and its occurrence led to a number of riots between the years of 1765 and 1852. The most famous of these was the New York Doctors Riot of 1788, which was sparked by children observing anatomists at work in a laboratory in New York. Rioters burned down the laboratory, and seven people were killed in the ensuing violence. In 1789, as a direct consequence of the riot, New York passed a law that made grave robbing illegal but allowed the bodies of criminals to be available for dissection.

Legislation was also enacted in other U.S. states throughout the latter half of the 19th century but remained patchy until the early 20th century, by which time the majority of bodies used by the anatomy and medical schools were those left unclaimed by relatives. In the United Kingdom, disgust over the activities of Burke and Hare led to the introduction of the Warburton Anatomy Act of 1832. This act guaranteed an ample supply of corpses by allowing the surgeons and anatomists to use the bodies of unclaimed paupers who died in the hospitals or workhouses. Thus, if the previous legislation, which allowed the dissection of executed felons, was viewed as a punishment for crime, the new legislation might easily be perceived as a punishment for poverty, and the act gave the poor a further reason to fear entry into the workhouse.

The Archaeologists

The proliferation of body snatching in the 18th and 19th centuries was a consequence of growth during this period, of the quest for scientific knowledge. Alongside the anatomists' desire for greater understanding of the workings of the human body was a concern to learn more about human societies through the ages. The burgeoning discipline of archaeology was also involved in removing artifacts and bodies—long dead as opposed to fresh ones—from the grave.

Although not usually considered to be grave robbers, archaeologists have been accused by a number of indigenous community groups as having stolen bodies from the graves of their ancestors. This charge has led to demands for the repatriation of human remains currently lodged in museums in the West.

In the pursuit of knowledge and scholarship, early archaeologists frequently opened graves, removing artifacts, bones, and in some cases mummies. Perhaps the most notable case was that of the discovery of the pyramid of the young pharaoh, Tutankhamen, whose previously undisturbed tomb Howard Carter famously excavated in 1922, removing precious artifacts and the mummy of the king himself. The media images taken at the time show archaeologists carefully removing item after item of grave goods buried with the young pharaoh to assist him along his journey to the afterlife.

In some cases the opening and removal of items from graves may have resulted in the destruction of bodies and skeletons when the human remains were not perceived as being important or significant—for example, when the primary aim of the exercise was the sale of treasures to private or public collections. In other cases human remains were treated as objects, and their careful removal

was ensured so that they could be placed on public display in museums or traveling exhibitions. Indeed, many museums in Western countries such as the United States and the United Kingdom are replete with skeletons, bones, skulls, and mummies taken from ancestral graves.

The moral distinction between grave robbing and archaeological inquiry is founded on the perception of scholarship and the quest for knowledge that can only be attained by "digging up the past." It also rests on community and personal religious beliefs about the appropriate treatment of bodies, resurrection, and the nature of the afterlife. Thus, whereas scientists might argue that they need to retain human remains in museums in order to continue to generate knowledge about the lives of earlier peoples, many indigenous groups are now demanding repatriation of the remains of their ancestors. The latter are vehement that this practice is tantamount to an infringement of human rights.

One particularly interesting aspect of this discussion of the removal of bodies from graves is the degree to which the practice is perceived as an immoral act of theft according to the length of time since the burial. Thus, while preserved bodies found in shallow graves in the peat bogs of Ireland and Scandinavia might be viewed as an ethical source of information for scientists, recently dead corpses removed from the graves of countries in modern-day Europe and the Americas are not. To a large extent this distinction is due to the likelihood of there being surviving relatives and to shared religious belief systems, such as those within Christianity that assume deceased people should be allowed to "rest in peace" and not be disturbed in their graves.

There is also a cultural dimension, however, in that within Western societies time is an important factor. In many non-Western cultures time has little or no consequence for communities who believe that people are at one with the land and that their populations are linked, in an unbroken human chain, with their ancestors. Such is true of the Māori population of New Zealand on whose behalf a successful claim was made for the repatriation of two *toi moko* (tattooed heads) from the Perth Museum in Scotland. While the activities of the body snatchers were clearly immoral in that the theft and use of those corpses were against the wishes of both the deceased and the family, the issue for archaeologists and museum curators is whether the pursuit of scientific knowledge takes precedence over the cultural claims of indigenous peoples. The ultimate question here is that of whom the dead belong to.

Green Burials

Green burials use environmentally friendly techniques to dispose of bodies and minimize the financial costs associated with funerals. In general, green burials require biodegradable coffins or shrouds if anything is used to cover the body at all. Burial sites are planted with native plants, grasses, and trees. Any practice or substance considered polluting or unnatural is discouraged. Allowing the body to decompose naturally while using as few resources as possible is the goal.

Green burials can take place at one's home, in conventional cemeteries that support such practices, or in green cemeteries. Green cemeteries require biodegradable substances to be used on and around the body; they do not allow embalming or vaults. Such graveyards create and maintain native plant ecologies. They do not use pesticides

or fertilizers. Aiming for a native habitat appearance, artificial markers such as engraved headstones are not permitted nor are lawns planted and maintained. Other terms used to describe green burials are *natural burials*, *woodland burials*, and *ecological burials*.

Green burials challenge the environmental costs of contemporary funeral practices. Conventional burials put toxic substances such as embalming fluid (which contains formaldehyde) and natural resources such as hardwoods, steel, copper, and bronze into the ground. Furthermore, the use of pesticides, fertilizers, and lawnmowers to maintain conventional cemeteries pollute soil, water sources, and air. Even cremation, a source of body removal that impacts the environment less than conventional burial practices, uses energy resources to incinerate bodies in addition to being a source of mercury and carbon emission. Although cremation can be used in green burials, it is considered less ecological than natural decomposition.

Green burials also confront the high costs of conventional burials. The National Funeral Directors Association estimates that the average cost of a funeral in the United States was $6,500 in 2004. This figure does not include payment for a cemetery plot or other cemetery fees.

History of Green Burial Movement

The contemporary green burial movement has its roots in the United Kingdom. Three psychotherapists—Nicholas Albery, Josefine Speyer, and Christianne Heal—founded the Natural Death Center in 1991. Inspired by the natural birth movement (with its emphasis on home births and family participation), Albery, Speyer, and Heal wondered if there was a more natural way to die than in a hospital surrounded by noise and machines or being embalmed and buried in suburban-style graveyards. The Natural Death Center provides information on how to arrange inexpensive, family-organized, and environmentally friendly funerals.

Ken West created the first natural burial ground in Carlisle, Cumbria, in the United Kingdom in 1993. The Carlisle burial ground aids conservation efforts by planting a locally grown oak tree on each grave. Family members are usually present at the tree planting. No gravestones or markers are used in the burial ground. Instead, names are placed on a wall at the perimeter of the woodland burial area. Such practices thus maintain local habitats and involve families in conservation efforts.

In 1994, the Natural Death Center started the Association of Natural Burial Grounds, an organization that promotes the creation and implementation of natural burial grounds. The United Kingdom movement highlights the use of burial grounds to create woodlands in part to conserve land in the face of continuing development. It has not, however, created standards of certification for burial grounds.

Contemporary Green Burials

The United Kingdom leads the natural burial movement with approximately 200 natural burial sites. The United States has the second most robust green burial movement. The first green cemetery in the United States was the Ramsey Creek Preserve, which is located in South Carolina and opened in 1996. Natural burial grounds also operate in New York, Maine, Texas, and Georgia, and more cemeteries are scheduled to open in the upcoming years.

To further promote and standardize green burial practices in the United States, the Green Burial Council, an independent, nonprofit organization, was created in 2005. The Green Burial Council works with funeral directors to increase options for green burials, certifies crematoriums that meet fuel efficiency and antipollution standards, and certifies green cemeteries. The organization has two categories of certification for cemeteries: conservation burial ground and natural burial ground. A conservation burial ground cemetery involves an established conservation partner and explicitly aims to promote land conservation. Conservation burial grounds use native plants and trees, biodegradable burial containers and shrouds, and living monuments (e.g., native trees) or rocks and boulders appropriate to the landscape, and they ban toxic chemicals and vaults. The natural burial ground category shares conservation burial grounds' use of native plants, living memorials, and toxic chemicals and vaults ban. This type of green cemetery, however, does not require partnership with an established conservation group or agency, nor does it mandate an explicit conservation goal.

Green burials have received positive coverage from mainstream and alternative news media and

popular culture. For example, the HBO television series *Six Feet Under* had Nate Fisher, one of the show's main characters, choose a natural burial in the fifth season. A funeral director by profession, Fisher rejects embalming and conventional cemeteries and opts for an environmentally friendly return to the earth. Poi Dog Pondering, a Chicago band, evokes the tenets of natural burials in their song "Bury Me Deep." The lyrics state, "Don't incinerate me or seal me from the dirt which bore me, the bed that which from the rain falls upon and the fruit comes from. For the dirt is a blanket, no fiery tomb."

Other countries are beginning to promote green burials and to form organizations that will support such endeavors. For example, the Natural Burial Cooperative, Inc., an organization that aims to develop green cemeteries across Canada, was formed in 2006. Italy, Australia, China, New Zealand, and other nations promote ecological alternatives to body disposal and are exploring the development of natural burial grounds. "People plantings," as Billy Campbell, the founder of Ramsey Creek Preserve, calls green burials, are desired by consumers worldwide.

Grief, Bereavement, and Mourning in Cross-Cultural Perspective

Although death cannot be measured scientifically, the concept of culture provides the key medium for understanding the final boundary between our existence as living beings and the inevitable end of that existence. Death is a phenomenon of life, but consciousness of mortality is a social, not a biological, reality, because our knowledge about death and its meaning and value is socially constructed.

Most recent writings about grief and mourning are grounded on research conducted with subjects who live in North America and Western Europe. This research uses theories and methods that grew from the same geographical area and historical period. And although reports about mourning and grief come from many cultures, there is no accord among bereavement scholars about what concepts best explain the ways in which individuals and communities respond to death, grief, and mourning in different cultures. Exact definitions of culture are elusive, like the concept itself.

At the most general level, culture is defined as those aspects of human activity that are socially rather than genetically transmitted. Thus, culture consists of patterns of life passed among humans, which apply to every domain in society: religious beliefs, folk practices, language use, worldviews, and artistic expression.

History of the Concept of Culture

The origins of the concept of culture date back to the work of early post-Enlightenment folklorists who used the concept to avoid the uniform theories of human capabilities that were characteristic of the late 18th century. The modern concept of culture was developed later partly in response to racist and biological determinist ideologies of the 19th century, most of which incorporated an evolutionary framework based on social Darwinism. *Homo sapiens* was viewed as divided into separate subspecies or races, each with an essential characteristic, a system that included a hierarchy of moral worth.

Philosophers maintain that a general problem with the culture concept is that it is often linked with a naive relativism, precluding judgments about the unique cultural practices found around the world. In many cases practices dealing with death that were unsettling to Europeans, such as head hunting and ritual cannibalism, were the focus of disproportionate attention, supporting efforts to justify and document a radically different "other." The anthropological engagement with

mortality dates back to the origins of the discipline, and it is bound up with concerns about the origins of religion. Early theorists focused on small-scale societies where magic, science, and religion were not separate cultural domains. For example, the 19th-century anthropologist Edward Tyler, who worked from an evolutionary paradigm of explanation, viewed the origins of the human society and culture in efforts to explain mortality and, in particular, in the recurrence of dreams and other visions about deceased close kin. Social theorists influential to the development of anthropology, such as Émile Durkheim and, later, Robert Hertz, argued that all societies exert institutional controls to protect and preserve the life of the members, including rules governing appropriate and inappropriate killing.

Many actions that appear to be individual choices, such as suicide or the expression of the emotion during grieving, are actually socially patterned, as studies such as Durkheim's comparative analysis of suicide rates illustrates. Hertz used cross-cultural comparisons of mourning rituals to suggest that the human expression of grief can be understood also as a social fact, peculiar to each society. Scholars focused on the recurrence, throughout the world, of death ceremonies that expressed fertility and rebirth. The emphasis on sexuality, and the connection between sex and death, fit well with interpretations of ritual behavior that emphasized function. Death rituals serve the function of reintegration of society following a death, focusing on reproduction.

In some societies this symbolic link between death and regeneration is expressed explicitly; for example, some funerary practices incorporate the abandonment of usual standards of sexual propriety for a confined time period, or allow and encourage sexual relationship between categories of kin where such contact is generally excluded. These rites of passage seem designed to guide the passage of humans through dangerous, liminal transitions, marking the boundary between life and death—hence the association between funerals and other rites of transition such as initiation ceremonies.

In contemporary Western society, the practices of bioethics developed in the past several decades have become the new rituals guiding the transition between life and death. A number of studies in anthropology and medical sociology offer accounts of the disclosure of a terminal diagnosis to children under treatment for leukemia. One such example is David Sudnow's account of dying in a public hospital.

Grief and Mourning as Instinctual Responses

From a biological perspective it appears that grief is a universal phenomenon. In every culture people cry or seem to want to cry after the death of someone who is significant to them. Grief, therefore, could be envisioned as an instinctual response, shaped by evolutionary development. Many species of animals perhaps grieve. Birds, dogs, and primates display behaviors that seem equivalent to human beings in reply to separation and death. Instinctual reaction in this sense is a meta-interpretative scheme programmed into our genetic inheritance. The response is aroused by the perception of distinct situations (e.g., damage, success or failure, education opportunities).

Culture, indeed, influences how people evaluate situations, and similar perceptions of events trigger similar instinctual responses. A significant death, then, might be regarded as a universal impulse of grieving emotions, although which death is significant enough to spark such a response depends on the value system of a particular culture.

Universal Instinct Theory

The theoretical emphasis on universal instincts has generated a large body of research and practical findings useful to clinical practitioners. In universal instinct theory, a significant death causes a response much like that which a child feels upon separation from the mother. In the beginning the child protests and makes an attempt to get back to the mother; soon afterward the child despairs of returning to the mother but remains preoccupied with her. Grief after a significant death follows the same preprogrammed sequence of behaviors.

Attachment

Attachment is an instinctual behavior that has survival value because it keeps the child close to the mother for protection from predators. Human beings are attached to individuals all through their

lives, and when they die, individuals experience separation and loss and so must reorganize their attachments to match the new reality. Some recent grief research suggests that attachment styles in childhood predict bereavement style in adulthood. Contemporary attachment theorists have asserted that attachment is biological and, though influenced by culture, still functions similarly in all cultures. Furthermore, the template used in attachment bereavement theory is the reaction of young children when separated from their mothers.

Grief

In grief, the theory holds, adults are all like children, looking for reunion with the departed person. The theory does not recognize that as people mature, their attachments become broader.

The young child perceives his existence only in relationship with the mother. As the child matures, each level of social membership or identity is also an attachment such as to the social group, community, tribe, nation, and religious tradition. At each level, separation becomes a less probable explanation for grief because attachments to individual people become embodied with social systems and cultural meanings that cannot be narrowed to biological heritage.

In the individualistic culture of modern Western world, with its destroying attachments to larger social systems, primary social relationships are restricted to the nuclear family. Such individualistic relationships resemble but do not duplicate the genuine mother-and-child bond. Death may arouse instinctual responses other than those that are marked "grief." In Western culture, for example, this arousal may be a trauma response.

It may also be that the trauma reaction is as universal as the separation reaction in attachment.

Trauma and loss are different meta-interpretative schemes. In the Western society some deaths are traumatic, some traumas are not connected with death, and some deaths are not traumatic. In modern Western culture, rape evokes a response close to that of a traumatic death. Other cultures may have meta-interpretative schemes that can be related to death (revenge, submission, and purification) but may not be pertinent to the modern Western culture. In traditional Chinese culture, for example, grief is interfaced with the problem of pollution.

One of the purposes of the funeral rituals was to protect men from pollution while women took the pollution on themselves, thereby purifying the deceased for the afterlife. Death presents pollution or powerlessness in some cultural contexts as much as it presents separation, loss, and sometimes trauma in the modern Western society.

Cross-Cultural Instinctual Theory

As researchers develop a cross-cultural theory of instincts, they will cast their attention to other instincts much as they have given to attachment and trauma. At a symbolic and metaphoric level, death is used to understand other realities in human existence. One way to find the instincts evoked by death might be to consider a culture's use of death as a metaphor. For traditional Chinese women, death was like marriage, encompassing mutual obligations between the living and the dead. In the West the concept of grief is applied to other separations and losses, such as divorce, and to other traumas, such as home invasion.

All people are shaped, to some extent, by the culture into which they are born and raised. The human expression of grief is no less a product of culture than are marital or religious customs or symbols. How individuals and families cope with dying, death, grief, loss, and bereavement is as unique as a fingerprint. The reaction to the death of a family member, relative, or close friend places one in the category of *bereaved*. Those who are bereaved experience *grief*, a person's response to loss, which encompasses physical, psychological, social, and spiritual components.

How one copes with other life events and adapts to one's present and future is also part of the grieving process. A public ritual such as a funeral or memorial can offer powerful closure for those suffering traumatic grief. The conclusion of grief often includes cultivating bonds of emotion and meaning with the dead. People who are important to us become part of our inner conversation and remain there after they die. They may continue to play important roles in our lives and inside the community for many years after they have died.

Throughout history this particular persistent communion with the dead has been a recurring behavioral pattern, far more common than an outright severing of all bonds. Western psychologists

became interested in individual grief—the ways in which survivors live on after a death—precisely at the time when the cultural narrative about afterlife had begun to wane.

Continuing bonds with the dead in individuals and families became integrated into the collective representation that mediates the culture to the individual.

Durkheim affirmed that collective representations play a major role in developing social solidarity and identity in tribes, ethnic groups, and nations. Grief and the ceremonies of mourning place the dead into collective memory as well as into the individual memories of those who knew them. The memory of soldiers who die in war, for example, is evoked during patriotic celebrations in every culture. In Chinese ancestor rituals, the dead remain part of the family, defining the values by which the family lives and creating the shared identity of the living members of the family.

The memories of martyrs energize living people who believe in the ideas or causes for which they died.

Grief and the Boundary Between Life and Death

The concept of "social death" has been of remarkable utility in describing the varied boundaries between life and death throughout the world, and it is intimately tied up with notions of self and who counts as a person within a society. Scientists observe and document societies in which full-term infants are not considered fully alive, and thus not considered members of the social group, until they have survived the first month of life (perhaps not by chance the period of highest vulnerability for newborn) and received a name in a formal naming ceremony. Those who die before naming are not considered fully human and thus do not warrant ritual attention, such as funerals or elaborate mourning rituals.

Such practices are in sharp contrast with contemporary obstetrics practices in the first world, where developing fetuses are named and ultrasound images are exchanged prior to birth.

Indeed, the survival of extremely premature infants in neonatal intensive care units is best understood as an artifact of culture. In other societies, specific kinds of births (such as twins) or certain infants (such as albinos) may be judged as incompatible with life and thus viewed as already dead or vulnerable to infanticide. In Bariba African society certain infants are understood to be witches, and thus mothers are not allowed to grieve the loss because the infant is defined as not human and potentially dangerous for the entire community.

All societies have rules about how emotions of grief are to be displayed and handled. For example, a common way in the West of dealing with grief is to talk about one's experience, one's relationship with the deceased, and one's feelings. But in some cultures, talking may disrupt hard-earned efforts to feel what is appropriate, and to disrupt these efforts may jeopardize one's health. In some cultures, talk is acceptable, but one must never mention the name of the deceased person. In other cultures talk is admissible as long as it does not focus on oneself. Even in Western society, however, not everyone is open to talking.

It is important, however, not to consider those individuals who do not openly express their emotions as pathological. In fact, the idea of pathological grief is primarily a Western construction; in other cultures the labels would be different but with a common purpose: conforming people to the social rules. There is enormous variation in what is considered appropriate behavior following death. The ideal among traditional Navajo is to express no emotion, while in tribal societies a death may be met with outpourings of grief, including self-mutilation.

In contrast to clinical notions of pathological grief, in some Mediterranean societies widowhood was considered a permanent state of mourning, and mourning clothes were worn for years, if not decades. In a recent compelling book titled *Consuming Grief,* Beth Conklin describes how a South American native population, as well as a Papua tribe, assuage their grief by consuming the body of their dead kin.

In some traditional societies, to avoid being a burden to the wider community, elders choose to end their own lives by exposing their bodies to the elements; the perhaps apocryphal Eskimo on an ice floe provides a powerful image whether or not supported by the ethnographic evidence. Or mothers may withdraw their attention from a child deemed unlikely to survive in an exhausted environment like the slums of northeastern India. The

Wari native inhabitants of the Amazon respect their dead, and relieve their grief, by participating in ritual mortuary cannibalism.

It is helpful to consider how taking an anthropological or cultural approach to the study of grief differs from the approaches taken within philosophy, where the mystery of death has been a topic of speculation and discussion for thousands of years. Philosophy has attempted to account for death conceptually: Death is a state following upon the end of life; it is the absence of life. By contrast, cultural critiques begin with a set of social issues that move beyond the individual to focus on how different societies manage the existential fact that all members will eventually die and on the practical implications of the death of individuals, including the reintegration of survivors of a death. Ethnographers, anthropologists, sociologists, whether studying tribal and hunter-gatherer societies or contemporary intensive care units, have a quite different task: describing the range of culturally patterned responses to the existential realities of eventual human frailty and death.

The Importance of Afterlife in Cross-Cultural Perspective of Grief

The fear of death and the belief of life after death are universal phenomena. Human consciousness cannot have access to one's own death as an inner experience because death is an inevitable personal experience, which remains outside of individual self-reflection during a lifetime. However, throughout their lives human beings may be witness to several deaths, for the quest of the survivors after the substance of death follows the same cognitive scheme as when they think about the substance of their own mortality. Whenever we imagine ourselves as dead, we are as present in the picture as those who do the imagining; our living consciousness looks at our dead bodies. Therefore, when speaking about the cognitive ambivalence of death, there is the simultaneous presence of the feeling of uncertainty emerging from the taboo character of death and the knowledge of its ineluctability.

This constellation normally constitutes a powerful source of anxiety. To reduce the anxiety emerging from the ambivalence of death, every culture engages in anthropomorphizing. The essence of this mechanism is that individuals perceive death and afterlife on the pattern of their life in this world, by the projection of their anthropomorphic categories and relations.

Anthropomorphizing the ideas concerning the other world, the process called secularization, is present in all religious teachings with greater or less intensity. It can also be found in folk belief systems that are not connected to a church or religious issues. According to the members of the European peasant communities, for example, the surviving substance generally crosses a narrow bridge over a river to reach the other world. The most widespread idea is that of a world analogous to ours but more pleasant and of a society organized in the same way as it is on earth.

Grief, Bereavement, and Mourning in Historical Perspective

The common root of the words *bereavement* and *grief* is derived from the Old English word *reafian*—to plunder, spoil, or rob—which gave name to the *reavers*, bands of murdering bandits who terrified the uncertain lands between England and Scotland. Thus the root of the words *bereavement* and *grief* designates abrupt, violent deprivation with the resultant loss typically involving the soothing or cheering reaction of the soul. These two aspects of loss by death—the sense of

personal violation and the heaviness of the soul—are thus enclosed in the language itself.

The clinical study of reactions to loss began in the early years of the 20th century with the publication of Sigmund Freud's 1917 classic essay "Mourning and Melancholia," in which Freud includes the behavioral and emotional changes that are set in motion after a significant death under the single term *mourning*. The term has been used to cover the wide variety of reactions to loss and later to affirm that there is a difference between grief and mourning. Thus mourning is described as a public act of expressing grief that is culturally determined and distinguishable from individual spontaneous responses.

Another important theoretical approach acknowledges that both grief and mourning are subject to considerable modification, depending on the history and circumstances of the bereaved. Thus mourning is the conventional behavior, determined by the habits and customs of the society, whereas grief is a set of stereotyped responses, psychological and physiological, of biological origin. In contemporary thinking, this distinction continues to be assumed.

Finally, brief definitions of the key concepts can be offered: bereavement, the loss of a significant person in one's life, which characteristically generates a reaction we call grief, which is evident in a set of behaviors we call mourning. Grief has been described as mental pain, distress, and deep or violent sorrow associated with bitter feelings of regret for something lost. Mourning, on the other hand, has two aspects: one subjective and rooted in anxiety, fastening, remembrance, dying, and withering, and the other in the public expression of grief and the exhibiting of conventional or ceremonial signs of grief such as wearing the appropriate garments or respecting pertinent social traditions. Many theorists, then, have indicated that while loss and grief are universal in humans and present, to some extent, in certain other species, mourning is culturally determined.

The Early History of Grief, Mourning, and Bereavement

Although a sense of loss, and therefore grief, may extend back at least to the time when the first anthropoids were recognizable as human, it is only in relatively recent years and in some societies that entire industries have grown up around death and its aftermath. Many primordial myths contain the idea of a golden age before the existence of death, and suggest that it was called into being by some mistake or to keep humankind from challenging the gods. Ancient stories and legends also speak of the struggle humankind has long been engaged in to come to terms with the finality of death and to deal with its aftermath in individuals and societies.

Early writings inform us that bereavement was known as a source of physical and mental disturbance in those left to mourn. In one of the earliest known poems in the English language, "The Wanderer" (ca. 850 C.E.), the poet mourns "Here possessions are fleeting, here friends are fleeting, here man is fleeting, the kinsman is fleeting . . . the whole world become a wilderness." In the early Greek myths, when the goddess Demeter loses her daughter Persephone, she loses "her gaiety for ever." Demeter shows the characteristic restlessness and emotional turmoil of acute grief: She seeks her child for 9 days and nights without rest, food, or drink, and when she hears that Hades (death) has taken her, she is so angry that she is ready to destroy everything living on earth. The desolation, restlessness, and raging against death shown in these ancient legends are familiar to us today. Now, at the beginning of the 21st century, the methods of inquiry and the core of interest may be new, but the struggle to make sense of death goes on essentially unchanged. To outline the historical perspective of grief, we must investigate the origins of that struggle.

Burial Activities

Knowledge of the behavior of our early ancestors, due to the absence of written records, is necessarily speculative, based as it is on the placing and types of ancient fragments, natural and manufactured, of their lives. We know that, at some point, probably between 50,000 and 80,000 years ago, human remains began to be buried or disposed of in a deliberate and sometimes ritualistic way. The adoption of these practices has delineated the transition from savagery to barbarism in coincidence with archaeological confirmation of significant changes in the economy of hunting groups. The

change from simply leaving a corpse for the natural processes of decomposition and predators to deal with, to undertaking the group effort of burial, is considerable. At the very least it indicates a concern with things other than immediate survival.

Burial has become a symbolic act; it can thus be regarded as a social act also, of significant value for the group. There is no basic biological reason for humans to have expended time and energy, that might otherwise have been devoted to the acquisition of food, to the burial of the dead. It appears to have been selective; that is, not everyone was accorded burial. Grave goods have been found in some very early tombs and, although it has been argued that on some sites the placement was accidental, there are instances of flint knives placed in the hands of corpses.

Other evidence of symbolism includes red ochre having been strewn on the body, placement on a bed of seashells, crowns of goat horns around the head, animal skulls in the corpse's hands.

Even if we cannot know the precise intentions of those who buried their dead in such a way, we may deduce that they continued to care for that member of their group even after death as they protected the body. They also kept the body close by: Intentional burials are associated with dwelling sites, and available evidence suggests that care of the body and the implication of thinking about its disposal were important. The evidence collected from these early burials may be taken to imply the capacity to imagine, to have a sense of an "other" which cannot be seen or experienced directly, and to acquire a consciousness of the future.

Death as a Basic Social-Cultural Concept

Homo sapiens developed the competence for symbolic thought, and along with this capacity emerged ideas of the journey associated with death, of leaving the body when it died, and continuing existence in another form, elsewhere. But, as larger social groups formed and increased in number, after the progression of an agrarian economy and the expanding use of tools, the ritualistic disposal continued to be selective and became more elaborate.

There are many indications of religious formalities, such as burial hills positioned to the rising sun and sacrificial marks on or near some grave areas. Thus it appears that from our earliest days there have been rituals concerned with death that were important enough to involve the community in hard physical work implying continuation elsewhere, as the notion of a spirit or soul released from the body to journey on.

These two aspects of funeral rites—messages about the strength of the ongoing group and its configuration and messages about the change death has made to the individual member, who is now elsewhere—are universal. These are expressed in many different ways across cultures and throughout history, and a great number of religious convictions are associated with them and the fate of the soul. In ancient Egypt pharaonic tombs became so complex that they had to be planned well in advance of the death of the pharaoh. The pyramids were expensive in terms of working hours, materials, and lives of the workers. The bodies of those high in social position were preserved by mummification and buried with expensive grave goods, but nobody knows what happened to the bodies of the common citizens, the poor, or the slaves. In early China, for example, members of the household of a high-standing personage were sometimes murdered on the occasion of his or her death and buried in a huge tomb with their lord or lady.

In Northern Europe, Viking heroes and kings were buried in ships filled with food, jewelry, and weapons to ensure the dead would have all that was necessary for life after death. Wives, mistresses, horses, and dogs were killed and laid to rest with the deceased Viking. The ships were covered with mounds of soil or set afire and let sailing off the coast. These historical facts say nothing directly about personal grief; they only reveal its public face. But these facts are important, based as they are on the treatment accorded to dead bodies.

From History to Early Philosophers, Understanding Grief

For both humankind generally and each living person individually, the recognition of the universality and inevitability of death is but the beginning of the problem of death. Indeed, recognizing death as the individual and collective fate of human beings, and of all living creatures, creates the problem of death: Why does it happen? What does it mean? Is death final? As such questions emerge, so do other issues that are provoked by death: What is the

meaning of life, its purpose? Can life be meaningful if it ends in death?

Philosophers have struggled with the human fear of death, trying to alleviate grief and mourning. Recognizing the inevitability of death is very different from supposing death is final.

At a very general level, philosophical and anthropological reflections on death divide those who deny the finality of death and suppose there is ongoing, usually individual, self-consciousness after death, and those who regard bodily death as final, as the destruction of consciousness, but who offer consolation meant to assuage fear of the inevitability of personal extinction. A few philosophers have found death to be inevitable, final, and horrible.

What binds together in a recognizably Western tradition are the analytical approaches each group takes and the exclusively human-centered character of their views. Probably the single most persistent theme in Western reflection on death is the view that death is not the annihilation of the self but its transformation into another form of existence.

The conviction that individual human beings survive death, perhaps eternally, has been very differently grounded and elaborated in the history of mankind, but in some form it has persisted and frequently dominated through antiquity, the long era of Christian theologizing, modernity, and into contemporary postmodern thinking.

Considerably less attended to is the attempt to reconcile human beings to death's finality, to death as the end of individual human experience beyond which there exists no consciousness.

The tension in Western society between regarding death as transformation and thinking of death as final appears, at the very outset of what conventionally is regarded as the beginning of Western philosophy, in the fragmentary remains of writing that have survived from thinkers in the early Greek colonies of Asia Minor, especially the Ionians.

The attempt to reconcile opposites, such as life and death, and to perceive the underlying unity, even harmony, in all of reality was preeminent for the pre-Socratics. Anaximander (ca. 610–547 B.C.E.) and Heraclitus (533–475 B.C.E.) were singularly impressed with the transitoriness of all things, as captured in the best-known corruption of a Heraclitean fragment, "One cannot step into the same river twice." The earliest surviving pre-Socratic fragment, from a document attributed to Anaximander, contains the evidence of how impressed he was with the terrible fact that things perish but also expresses the hope "that somewhere and somehow death shall have no dominion." Despite the appearances, death is not annihilation: In the everlasting boundlessness (*apeiron*), individual death is not meaningless, perhaps not even final.

In southern Italy, Pythagoras (ca. 572–497 B.C.E.) struggled with the same realities, teaching that the soul suffered from embodiment, longed for release and reunion with the divine (possibly as death experienced transmigration into other life forms), and could be partially purified through the process of rebirth. For the purification needed to overcome death and to be evermore united with the divine, it was most important to live a philosophical life, especially one that paid considerable attention to the contemplation of mathematical truth. Permanence and impermanence, constancy through flux, continuity and change, death, extinction and recurrence are the enduring concerns of pre-Socratic scientists.

Socrates' (ca. 470–399 B.C.E.) view of death seems to be rooted in the immediacy of his experience and circumstances, at a time when he is first anticipating, then under, a death sentence. More than the words that Plato and Xenophon report him to have said, it is the moral lesson Socrates sets that has influenced entire generations.

Indeed, the art of mastering the fear of death is not easily learned. Stoics recommend emulating great men, virtuously living the life of the philosopher, and always recalling that living well is by far the most important thing along with documented reminders of the futility of fearing or resisting death.

Grief and Mourning at Medieval Time

During the medieval era, death was a constant presence and dance, like other forms of art, has considered the matter of death throughout history. Rituals have surrounded the mystery of death from prehistoric times, and the reiterated rhythmic movements become dance, in some cases endowed with a therapeutic sense.

Funeral processions are an example of organized movement to music, expressive of grief. The *danse macabre* (*Totentanz* or "dance of death") of

the European Middle Ages was represented many times on the walls of cloistered cemeteries as a dance of linked hands between people of all levels of society and the skeletal figure of death. These painted images were performed in a period of affliction and fear caused by the bubonic plague, which swept the entire continent, murdering a large portion of the population.

The earliest known appearances of the danse macabre were in story poems that reported of encounters between the living and the dead. Usually the living were knights, bishops, or distinguished members of the society. The dead interrupted their procession saying that as they were, the living shall be, underlying the theme of the uncertain human fate. Neither strength nor piety can provide escape.

The danse macabre portrayed on the cloister walls of the Innocent cemetery in Paris no longer exists, but there are wood copies that represent the first haunting visual image. The picture contains four skeletons performing on bagpipe, harp, organ, and small drum. The dancers seem to move in a low, stately procession clearly resembling a ritualistic rather than a social dance, where all the players are following their leader: Death. During the plague (black death) years of the 14th century the danse macabre made its first appearance and became an increasingly familiar cultural element all over Europe: In Germany it was called *Totentanz*, in England *dance of death*, in Italy *danza della morte*.

Of the various explanations of the origin of the term *macabre*, perhaps the best-founded was that offered by the historian Philippe Ariès. He observed that the Maccabees of the biblical period were considered and venerated as patrons of the dead. Over the years the word *Maccabee* became a popular expression for the dead body, and Ariès found that the term still had that meaning in the folk slang of the late 20th century. The fearful images attended several purposes, to include assisting and encouraging people to manifest and share their grief; to remember that death is not only unavoidable but also the great equalizer, calling the high and the mighty as well as the humble; and to provide the opportunity for indirect control. When vulnerable mortals could paint, describe, and perform the danse macabre, they earn a subtle but perceptible sense of control. To overcome the sorrow of grief, the figure of Death was also increasingly subject to caricature. The strong human imagination had made Death a character, often honored, sometimes frightening, and, eventually, even comic.

Ars Moriendi

Ars moriendi, or the art of dying, as a body of literature provided practical advice for the dying and those attending them. By 1400 the Christian tradition had well-established beliefs and practices regarding death, dying, and the afterlife. The ars moriendi packaged many of these into a new brief format. The first such work appeared in Europe during the early 15th century, and forms of this writing lasted well into the 18th century. These manuals informed the dying about what to expect and prescribed prayers, actions, and attitudes that would lead to a "good death" and salvation.

During the previous century the black death had devastated Europe, and its reappearances (along with other diseases) continued to cut life short. The Hundred Years War between France and England was the era's largest conflict and the fragility of life under these conditions coincided with a religious shift, whereas the early Middle Ages accentuated humanity's collective judgment at the end of time; by the 15th century, attention focused on individual judgment immediately following death. Individual death and judgment thus became urgent issues that required preparation.

To meet this need, the ars moriendi emerged as an educational program to prepare priests and common people to face the social consequences of mourning and bereavement.

The Contemporary Experience

Considering the documented evidence from the Middle Ages to the present, historian Ariès has discovered a cardinal switch in behavior. Where death had once been familiar and "tamed," it was now untamed, "forbidden," and even, as Baudrillard said later, "pornographic." Medieval people accepted death as a part of life: Death was expected, anticipated, and consequently more controlled through rituals. Rural folk, in Western society, maintained such attitudes until the early 20th century,

The rise of modern science and the development of medicine led society to challenge beliefs in divine judgment, in heaven and hell, and in the

necessity of dying in the presence of a priest. Attention fell on the emotional pain of separation and on keeping the dead alive in memory. With each new attitude, Western Europeans distanced themselves from the old ways. Contemporary historians attribute the causes of change, even in collective attitudes, in more objective measures.

Grief, Types of

As social beings, our need to attach to others begins at the time of birth. In fact, our survival depends on meeting this need. Ongoing cultivation of this need leads to many significant relationships during our lifetime. However, when a loved one, to whom we had attached in a variety of ways, dies, it is often a devastating experience. A process of adjusting to this experience of loss is what psychologists label as a bereavement crisis. In Greek, crisis means turning point. During this turning point in our lives after losing a loved one, the intense emotional experience is called grief. Loss and grief go hand in hand and grief as a universal experience is a part of every person's life. Change in circumstances after the death of a loved one, difficulty in functioning as one had functioned before the death, and having to accept the unacceptable give rise to a multifaceted grief reaction. Even though it is a sad and painful experience, grieving is considered a necessary part of post-death adjustment. While no one is spared the challenge of dealing with loss and grief, the differences lie in the type and duration of grief experienced and how people cope with their losses.

Many experts have tried to explain the normal experience of grief in a variety of ways. Some explain grief by breaking down its course and components into stages or phases, while others describe tasks of mourning. These models of grief provide the frame of reference for the bereaved to conceptualize their experience of loss and its resolution. Regardless of the conceptual differences, a common theme in all these theories is that grief is a process and not a static event.

One of the original and best-known theories of grief is presented by Elisabeth Kübler-Ross. She identified five stages: denial, anger, bargaining, depression, and acceptance. This theory is applicable to both the patient who has been diagnosed with terminal illness as well as his or her family members. Following Kübler-Ross, many writers have presented their grief models with different numbers of stages or phases. A more simplified and inclusive view based on these models is that generally people tend to pass through three broad phases or stages of bereavement. These stages overlap and do not necessarily occur in a sequence. In fact, the bereaved individuals move back and forth between these stages as they work through them. And not everyone goes through these stages at the same rate and with same intensity.

An initial stage of shock, numbness, or disbelief is characterized by mechanical functioning and social insulation. This phase may last for minutes or weeks. The next stage of depression incorporates acute anguish with intensely painful feelings of loss that usually lasts from weeks to months. Finally, after months or even years, a phase of resolution involving reentry into a somewhat "normal" social life arrives. During this phase, the reality of the loss is accepted and intensity of grief symptoms diminishes. The grieving person begins to focus on the present and the future. An identity without the deceased is established and life can be enjoyed again. However, a normal progression through these phases or stages depends on a person's personality, type and nature of the relationship with the deceased, past experiences with losses, his or her present life circumstances, circumstances and nature of the death, and existing support system. Although people may successfully proceed through various stages or phases of bereavement, their perception of loss may always be there.

Along with understanding the progression of stages of grief, it is also helpful to understand different tasks the bereaved must perform to reach a satisfactory resolution of the bereavement process. To empower the bereaved, who are perceived to be not just passively passing through certain stages, J. William Worden proposed an action-oriented approach, which complements the stage theory and which consists of four tasks of mourning: (1) acceptance of the reality of loss, (2) working through the pain of grief, (3) adjustment to the environment in which the deceased is missing, and (4) emotional relocation of the deceased and moving on with life. Through these tasks, one works through various aspects of the bereavement process to achieve its completion and subsequent equilibrium. All theories of bereavement are focused on (a) helping the bereaved acknowledge their grief resulting from a loss, (b) understanding that it is normal to experience a variety of dysphoric physical and emotional symptoms, (c) directing the bereaved to attend to "grief work" because successful grief resolution is not automatic, and (d) knowing that the bereavement journey has a final destination of acceptance and moving on with life.

Symptoms of Grief

Grief is manifested in a variety of symptoms, such as disbelief; shock; numbness and feelings of unreality; anger; guilt; sadness; periodic crying; preoccupation with the deceased; sleep disturbance; difficulty in concentrating on tasks; loss of appetite; weight loss; loss of interest in other people and activities; lack of energy; irrational hostile feelings directed toward the deceased, God, or someone else; intense yearning for the deceased; and smelling, seeing, or hearing the deceased. This is not an exhaustive list of symptoms. In fact, there is no complete list of symptoms of grief and they vary from person to person and situation to situation. Many symptoms of grief are similar to those experienced by persons with psychological disorders and are generally classified into four categories: affective, somatic, cognitive, and behavioral symptoms. The intensity and duration of grief depends on a variety of individual and situational factors unique to each individual's bereavement process. Important factors determining the intensity and duration of grief are one's level of attachment to the deceased, circumstances of death, nature of the death, and the personality makeup of the bereaved. Notwithstanding, it is normal for people to experience any range of dysphoric reactions.

Unlike in the past, grieving in this contemporary age is expected to be done expeditiously. One is expected to be at work a few days after a death occurs and to resume the level of productivity one had had prior to the death. Mourning is somewhat limited to the time of funeral. This is again unlike the past when many postdeath rituals and customs were observed and served to make people around the bereaved more sensitive to the distress and needs of the grieving.

Normal Grief

In the course of the normal grieving process, the grief symptoms gradually reduce and the bereaved person begins to accept the loss and to readjust. Some of the symptoms may return briefly on death anniversaries, birthdays, or other important occasions related to the deceased; this return of symptoms is considered normal. It is generally agreed that the average period of time for normal grief in American society lasts from approximately 12 to 18 months. If one's grief-related behaviors continue beyond this time frame, the grief may be considered unresolved, complicated, or pathological. However, in certain losses such as loss of a child, this process may be expected to last 4 or more years. Usually if the grieving process continues in high intensity beyond the culturally defined mourning period, it may lead to clinical depression. About one in five bereaved individuals are eventually diagnosed with major depression. Individuals at highest risk for major depression are those with prior episodes of depression, with alcohol- or drug-related problems, without an adequate support system, and/or concurrently facing other major life stressors.

Anticipatory Grief

Normally, the bereavement progresses from denial to acceptance in a culturally prescribed manner, except when someone has a terminal illness or develops a debilitating disease, such as Alzheimer's, that robs him or her of faculties. The initial phases

of bereavement are experienced by the family and friends in advance before the death. This kind of grief is called anticipatory grief. Family's protectiveness, overinvolvement, and unresolved issues may complicate the grieving process for both the patient and the family. The family members may experience conflicting emotions due to the prolonged nature of the crisis. On one hand, they dread the death of the loved one; on the other hand, they hope for closure and an end to the crisis. They may feel anger with the loved one for becoming ill and wish for deliverance from the burdens of caregiving, and then later be consumed with the guilt of having such thoughts. Tremendous strain is often experienced due to the prolonged illness and waiting for death, which can be emotionally and physically exhausting.

The dying patient's anticipatory grief has two components: anticipating his or her own death and feeling responsible for the burdens and sadness of loved ones caused by the impending death. While the anticipation of death or profound decline of mental or physical health is very disruptive, it can be beneficial as well, because it cushions people to absorb the loss and complete unfinished business. The patient and the loved ones have time to prepare for death and say good-byes. However, anticipatory grief does not replace the grief felt after the death. In fact, the bereavement process cannot be completed until after the death, even though many tasks of bereavement are completed while waiting for the death to occur.

Disenfranchised Grief

Sometimes people experience losses that are not considered significant, socially recognized, or publicly mourned. Such losses lead to what is called disenfranchised grief. Some examples of situations when disenfranchised grief may occur are aborted or miscarried pregnancy; stillbirth; disappearance of a loved one; death from AIDS; death of someone with whom the relationship is not sanctioned or recognized by the society, such as same-sex partners or extramarital lovers; or a past relationship, such as an old boyfriend or an ex-spouse. The disenfranchised grief may also be experienced by those who are considered incapable of grieving, such as persons with developmental disabilities or children. This kind of grief can also create problems in the workplace. Because of the limited opportunities to formally express the feelings of grief in nontraditional losses, disenfranchised grief often takes longer to resolve than the grief due to traditional losses such as losing a parent, spouse, child, or friend. The bereaved also may require professional help to complete the bereavement process.

Complicated Grief

All cultures contain normative expectations pertaining to normal grief reactions. These expectations are represented by the types of clothing, bereavement rituals, mourning behaviors, and acceptable length of time for mourning. Failure to meet one's cultural expectations for bereavement and mourning is often labeled as complicated, unresolved, or pathological grief. Grief can also become complicated if the progression toward resolution is disturbed or not attempted at all. In some cases, the bereavement becomes prolonged with intense grief symptoms that interfere with one's ability to function, whereas in others, it may appear as a complete absence of grief. The intense overwhelming grief symptoms of earlier stages become abnormal due to their persistence and duration. Even though others will recognize the prolonged and self-consuming nature of a person's grief, often the bereaved remains oblivious and unable to recognize the complicated nature of his or her grief. However, those few who are aware of their problem feel powerless to address it. There are many similarities in symptoms between complicated grief and some psychological disorders, such as major depression, anxiety disorders, and post-traumatic stress disorder. Usually the unresolved issues of a relationship are the predisposing factors for complicating the grief process for the bereaved. It is estimated that approximately 10% to 20% of the bereaved experience this kind of grief with the following symptoms:

- Chronic insomnia or other sleep disturbances
- Excessive and continuous preoccupation with the deceased and loss
- Experiencing physical symptoms similar to those of the deceased
- Death or illness fears or phobias
- Engaging in escape and reckless behaviors such as drinking, drug abuse, or promiscuity

- Inability to get back to the prior level of functioning at work, school, or in relationships
- Inability to talk about the person who has died
- Showing signs of depression, low self-esteem, or suicidal thoughts
- Exaggerated grief reaction to minor events related to the deceased
- Reluctance to change the room or move the belongings of the deceased

Clinical and scientific knowledge on this subject has identified several types of complicated grief, as presented in the next section.

Chronic Grief

When the bereaved continue to exhibit normal grief reactions for an extended period of time without coming to a satisfactory resolution, the grief becomes chronic. It appears to be an attempt on the part of the bereaved to keep the deceased alive by continuing the intense grieving process. The bereaved fail to complete the tasks involved in the process of mourning and fail to adjust to their environment without the presence of the deceased. The intense grief reactions that would be appropriate in the earlier stages of bereavement linger. These excessive and disabling grief reactions keep the bereaved individuals from returning to normal life. Their intense preoccupation with the deceased may manifest in frequent visits to the grave, their conversations centering around the deceased, continual sorting and arranging the possessions of the deceased, and keeping the room and possessions of the deceased as if the deceased were coming back. An ambivalent or dependent relationship with the deceased is usually the source of chronic grief. Those who experience chronic grief and cannot come to a satisfactory resolution are at greater risk of physical and mental illnesses. There is also a high risk of suicidal behavior.

Absent or Delayed Grief

Unlike the normal grief pattern, some people who lose a loved one may show absence or delay of normal grief symptoms. The delay in symptoms may last for months or years. They behave as if the death of the loved one did not occur or they could handle the loss without being emotional about it. However, a price is exacted for this denial and repression. At some later date, a full grief reaction may be elicited by a somewhat minor loss or even someone else's loss. Or the bereaved may experience a flood of emotions at the least expected times for which they have no understanding or explanation. Often the absent or delayed grief results from either a traumatic nature of the death or the inability of the person to take time to grieve the loss, either because of obligations at the time of death or the person's perceived inability to deal with the loss at the time the death occurred.

Inhibited or Distorted Grief

When grief is inhibited, individuals might be able to experience loss of some aspects related to the deceased but engage in denial of others. Few signs of grief may be demonstrated at the time of death, but later psychosomatic symptoms may develop or moodiness may set in as the bereaved becomes irritable and/or short-tempered. Some bereaved persons may distort the experience of grief by exaggerating one or more normal grief reactions, such as anger or guilt. They may also appear to be consumed by one or more extreme emotions. Complaints of headaches, heart palpitations, anxiety, and depression are common symptoms, as are displaced anger and hostility. These complications are experienced more intensely and frequently than normal grief reactions are experienced.

Unanticipated Grief

Sudden or traumatic deaths lead to unanticipated grief. Because of the sudden nature of loss, often the bereaved are unable to fully experience the normal grief reactions. Instead they may suffer from extreme feelings of bewilderment, anxiety, self-reproach, and depression, thereby making the recovery complicated. Because of the unexpectedness of death, there may be many regrets and lose ends identified. The bereaved may feel responsible for not preventing the death or may have a significant amount of unfinished business with the deceased, leading in turn to increased anger directed toward others. The prolonged grief experienced is further intensified by their need to understand why the person died and the search for the meaning in death. The unpreparedness often leaves the bereaved feeling vulnerable and out of control.

Their symptoms are similar to those identified as accompanying post-traumatic stress disorder and often require immediate intervention. If intervention is delayed, the symptoms might become chronic and more difficult to treat.

Masked Grief

Sometimes bereaved individuals might experience somatic or psychological symptoms or a maladaptive behavior, which at first does not appear to be related to the loss. Unable to recognize the relationship between the symptoms experienced and their repressed feelings about the loss, the bereaved may develop symptoms similar to those of the deceased, while at other times experiencing unexplained depression or paranoia. Repressed grief may also be acted upon through a maladaptive or delinquent behavior, such as promiscuity, drinking, gambling, and other self-deprecating behaviors.

Grief and Bereavement Counseling

The unique pain of grief has been recognized and described poignantly in some of the most ancient texts and oral traditions of world cultures, but it is only in the past 50 years that formal organizations and professions have evolved to address the specific social, psychological, and spiritual needs of those persons who have lost loved ones. As the field of grief counseling has grown, it has also diversified, drawing inspiration from evolving theories of grieving while continuing to respond to the needs of various groups touched by often tragic loss. As it has done so, it has also begun to attract the attention of social scientists who have evaluated and sometimes criticized the field, raising questions about its basic assumptions, its social role, and its clinical efficacy. Although present evidence does not support the conclusion that formal bereavement services are of benefit to everybody, it seems clear that they are of considerable help to many, and especially those who stand in greatest need of assistance.

Models of Bereavement Intervention

Some observers distinguish between bereavement support, counseling, and therapy on the basis of

who delivers the services and who receives them. Bereavement support most commonly describes informal mutual support groups for bereaved persons in the community, such as those offered by many churches or synagogues, as well as those affiliated with national or international organizations, such as AARP (formerly known as American Association of Retired Persons) Widowed Persons Services, Mothers Against Drunk Driving (MADD), or The Compassionate Friends groups for parents who have lost children. But this category can also include services coordinated by health or mental health professionals, such as hospice bereavement care or national networks of services like those provided by Cruse throughout the United Kingdom. In these models, support is commonly offered to all bereaved people, or all bereaved by a certain kind of loss (such as those who have lost children or who have lost a loved one to murder, suicide, or an impaired driver), irrespective of their level of demonstrated distress or psychological disorder. Support may take many forms, ranging from simple provision of psychoeducational material or lectures on grief and trauma, through annual rituals of remembrance, to home visits and support groups led by a veteran member of the group, typically without professional training. Such support services have the advantage of minimizing the stigma of bereavement and mobilizing community resources, especially in the form of the presence, understanding, and practical counsel of others who have "been there" (through having suffered a similar loss) and who are coping with their circumstance.

In contrast, grief counseling usually denotes services provided or facilitated by a trained professional, such as a nurse, social worker, counselor, or psychologist. Counseling is more often provided to individuals or families, though group counseling led by professionals is also common. Grief therapy shares these features but is usually distinguished by its assumption that the client or patient is struggling with a problematic reaction to the loss, such as a diagnosable case of depression or prolonged grief disorder. For this reason, programs that focus on prevention of future mental health problems, such as those for children who have lost a parent or sibling, might more appropriately be termed grief *counseling* rather than grief *therapy*, per se. Both forms of services are provided in a range of settings such as hospitals, clinics, and counseling centers, though they also are offered by therapists of several disciplines as part of their independent practice. Gradually there has been a move, especially in the United States, toward considering grief therapy a specialized form of practice beyond general counseling and therapy, supported by certification programs such as those organized by the Association for Death Education and Counseling. In practice, however, distinctions among most forms of bereavement interventions are inexact and overlapping, in part because many settings offer services in multiple formats (such as individual or group) by multiple volunteer or professional support personnel. Generally speaking, professionally conducted grief therapy is appropriate when community support services are inadequate to deal with bereaved people who are struggling intensely for prolonged periods because of personal vulnerabilities, such as a disposition to major depression or acute concerns about abandonment by another. It also can be indicated when the losses with which people must deal overwhelm both the bereaved and those who attempt to support them, such as the premature death of a young person or the murder of a loved one.

Theories of Grief Counseling and Therapy

Judging from published literature on bereavement counseling, it is probably safe to say that most programs and services place emphasis on certain common factors, animated by the common assumption that it is good, in Shakespeare's phrase, to "give sorrow words" in contexts that permit the expression of feelings related to the death of the loved one and its aftermath. In keeping with the historical primacy of a psychodynamic perspective with its focus on "working through" bonds with the deceased in the service of "letting go" and "moving on," such therapy provides opportunities to review the relationship with the deceased and find symbolic ways to "say good-bye" with the respectful witnessing of a caring professional or other bereaved people. However, grief can be shared and explored in media other than words, as through expressive arts therapies that use drawing, painting, collage, mask work, sandtrays, music, and more, to give symbolic form to emotions and meanings associated with the loss and, especially in group-based programs, to seek validation for them. In

cognitive-behavioral models of therapy, both individual and group services also have incorporated an emphasis on education regarding basic grief and trauma reactions as well as practical coping skills, such as guidelines for seeking social support from others.

With the advent of contemporary grief theories, bereavement interventions have begun to diversify to feature processes of adaptive mourning emphasized by the various approaches. For example, some group programs have been organized around the presumed stages of grieving, with a series of weekly discussions of such topics as denial, anger, bargaining, depression, and acceptance. Other therapists facilitate theoretically important tasks faced by the bereaved, such as acknowledging the reality of the loss, confronting the pain of grief, and attempting to adjust to a world in which the deceased is missing. Alternatively, some research-based programs have drawn inspiration from meaning reconstruction models of bereavement, using narrative procedures to promote retelling of traumatic losses in order to better integrate them into one's life story. Other therapists help clients oscillate between the dual processes of loss-oriented coping (e.g., managing the intrusions of grief, seeking to relocate the relationship to the deceased) and restoration-oriented coping (e.g., pursuing new activities and investments, taking on new roles). Finally, a number of therapists promote systematic exposure to strongly emotional cues of the loss, whether through concrete behaviors such as visiting the cemetery or sorting through the loved one's belongings, or engaging in symbolic imaginary conversations with the deceased in an empty chair, in order to seek understanding, forgiveness, and a sense of continuing connection. The outcomes of studies on the effectiveness of such procedures are summarized in the next section.

Research on Bereavement Interventions

Volunteer support services have developed chiefly as a humane response to the pain of the bereaved, and professional grief counseling has been given impetus by cultural trends that view some form of therapy as a legitimate response to a wide range of human suffering. Recently, these same interventions have attracted the attention of social scientists who have attempted to understand processes of adaptation after profound loss or trauma and how these can be facilitated by various programs and procedures.

Studying bereaved people over time—even those who have the intended benefit of therapy—has made it clearer how difficult and extended the process of adapting to loss can be for many. For example, children receiving family services after the death of a parent are at risk of protracted disruptions of mood and behavior, especially when the surviving parent has trouble maintaining open communication and effective structure and discipline. Conversely, parents who have lost children to violent death from suicide, homicide, or accidents typically struggle with traumatic symptoms and grief for years or even decades, and fathers in particular display little benefit from even systematic therapies offering opportunities for sharing and discussion of coping strategies. Such results suggest that grief therapy is not a panacea for the pain of loss and that some people and families do not benefit greatly from the therapies that have been offered.

Studies comparing the progress of bereaved people who are randomly assigned to either treatment or no-treatment control groups underscore this conclusion. Although most people who participate in grief counseling or therapy report high satisfaction with services and also improve over time, it cannot be assumed that such improvement reflects the effectiveness of therapy, as they might well have experienced a lessening of distress as a function of natural processes of healing, their own efforts, or the social support available in their families or communities. Currently, it remains a matter of controversy whether grief therapy can at times actually aggravate people's distress, perhaps by fostering rumination on their loss or, in the case of group interventions, overwhelming them with the negative emotions of others. However, most reviewers of the scientific literature would agree that the evidence for the general effectiveness of grief therapy relative to no treatment is surprisingly weak. In many studies of interventions that are offered to all bereaved people, regardless of whether or not they show serious signs of depression, anxiety, or disabling grief, those who receive treatment do no better than those who do not. Although resolving the question of why this is so requires more research, it seems probable that this largely reflects the resilience of the majority of bereaved persons, whose grief is broadly in a

normal range and who ultimately will adapt well whether or not they receive formal intervention.

In contrast, those studies that screen the bereaved for distress, that offer services only to clinically referred or self-referred clients, or that concentrate on complicated, prolonged, or disordered forms of grieving are far more consistent in supporting the usefulness of grief therapy. For example, one important study compared a 16-week therapy called complicated grief treatment (CGT) against a more general interpersonal psychotherapy (IPT) with a large group of bereaved people who met criteria for disabling grief. Guided by the dual process model of bereavement, therapists in the CGT condition promoted the dual goals of helping clients both process their loss and seek restoration in a changed world that required the development of new life goals. Key interventions included not only psychoeducation about oscillating attention to these two processes, but also manual-guided therapeutic procedures delivered in three phases. The first of these was termed *revisiting*, in which the client was encouraged to tell and retell the story of the loss with eyes closed, as the therapist prompted her or him to deeper emotional engagement with the narrative. Clients were then instructed to listen to an audio recording of the retelling between sessions to overcome tendencies to cope with the loss through avoidance. In the next phase of *reconnecting*, clients were encouraged to review primarily positive but also negative memories of the loved one, as the therapist cultivated a significant continuing bond. This work was continued in imaginal conversations, in which a renewed connection to the deceased was fostered through two-chair dialogue with the lost loved one with the support of the therapist. Finally, in the *restoration* phase, clients were encouraged to envision viable life goals for themselves if their grief were not so intense, and then begin to work toward these. IPT followed its usual procedures by linking symptoms of grief to interpersonal problems and working toward a realistic view of the deceased and the development of satisfying relationships. Clients in both conditions showed improvement over time. Significantly, however, CGT was shown to be superior to IPT in reducing symptoms of complicated grief and improving participants' work and social adjustment, although the two treatments yielded comparable outcomes on measures of depression and anxiety. Other studies also reinforce the conclusion that specific treatments for complicated or prolonged grief can be effective over a few months when they help clients think realistically and hopefully about their situation, develop perspective on their loss, and orient to a changed future. Interestingly, these therapies tend to share a focus on telling and exploring the story of the loss in detail, whether in oral or written form, offering support for exposure to its most unsettling features, and providing opportunities for reconstructing a life plan in the wake of bereavement. As research on their outcome continues to accumulate, there is reason to believe that bereavement interventions can play a valuable role in mobilizing support for survivors, especially in circumstances of traumatic loss, and can mitigate the impact of prolonged and complicated grief reactions.

Grief and Dementia

Grief is a part of everyday life, especially for those affected by chronic dementia. Grief can be defined as the personal experience of a loss. By this definition every time a person forgets a favorite pen or discovers that she or he is no longer able to accomplish a task of any sort, human beings grieve a loss. For the average person, losses are categorized on a continuum from very minor to major. This rational process takes place every day when a pen is missing and the person simply grabs another. However, a loss like the death of a loved one is a significant event. Persons with dementia exhibit a loss of memory, but what many observers do not understand is that they also lose their capacity for rational thought. Thus, when a person has dementia this continuum of rational responses to the various types of grief situations becomes unclear both to the person and to those who care for that person.

Everyone who knows and cares about the patient who is confronted with a terminal diagnosis like Alzheimer's disease is impacted. The patient diagnosed with Alzheimer's disease in particular will experience a slow decline in mental and physical capacity that can continue for many years. Sometimes referred to as "the long good-bye," Alzheimer's disease, the most common form of chronic dementia, is the source of tremendous grief and sorrow, but it is not necessarily a shared grief between the patient and his or her loved ones. Traditional wisdom in the field suggests that family members primarily experience anticipatory grief, but it is not clear as to how, or even whether, the patient is able to grieve a significant loss. Recent research, however, suggests that a more complicated picture exists and needs to be included in the understanding of those in clinical practice.

Grief and Families

References to the experience of grief as it relates to the persons and families impacted by dementia begin in the early 1980s. However, research into grief reactions of families did not begin until 15 years later, and research into grief responses of persons who have dementia has only just begun. Early references to the family experience of grief as related to a person with dementia promoted the assumption that dementia, like other chronic illnesses, would invoke anticipatory grief (i.e., grief that occurs prior to a loss). The logic of understanding the grief of a family in this way stems from the theory that dementia is a chronic illness, much like cancer or a stroke. More recently, however, Alzheimer's disease has been defined as a terminal illness; this definition challenges the validity of employing the classical perspective of anticipatory grief for family members.

Anticipatory grief parallels conventional grief in that both reflect the emotional reactions of a person to a loss. Whether the classic stages of grief as articulated by Elisabeth Kübler-Ross in her 1969 publication *On Death and Dying* or the more recent tasks of mourning that J. W. Worden has employed, in both instances an event is generally the starting place for the grief reaction. When dementia is involved, the starting point to begin the process of grief is less clear. Paradoxically, the end point is also different. While in classical grief, the grief process can go on indefinitely, for the family with a senior who has dementia, the end point of anticipatory grief will be the death of the loved one. At this point the family is faced with the question as to whether or not the death signals the start of a second grief process in a more classical format. In short the struggle for families is to determine when their loved one actually dies. Is the person gone when they no longer recognize anyone in the family or is it when the body dies?

Possibly the greatest challenge for anticipatory grief is in knowing *when* to grieve *what* loss. In theory, when the person with dementia either can no longer perform a particular function or can no longer remember some significant bit of information such as the names of family members, these would be points of loss and thus sources of grief. However, many persons with dementia have good days and bad days. Loss of memory or ability may be gradual over time. The more invested the family is in caregiving, the harder it may be for them to accurately identify when a particular behavior started or memory was lost. Frequently, the burden is on out-of-town relatives or other persons who see the senior with dementia only periodically to more accurately identify losses since their last visit.

A Stage Sensitive Caregiver Model

A recent development is a stage sensitive caregiver model, a model that is based on research that identifies distinct differences between the ways family members grieve. Isolating three stages each family member goes through, these parallel the stages involved in the advancement of the dementia process. The most striking distinctions reflect the distinction between adult child and spouse caregivers. In the first stage of grief, adult child caregivers are more likely to be experiencing denial and avoidance, refusing to acknowledge any future implications of the disease. Spouses, on the other hand, are much more reality oriented and ready to face the future. The role of denial or relative lack of denial is made up when movement takes place to the second stage. For the adult child in the second stage, there is a rapid transition to the reality of care and the experience that the burden is much greater than expected. For the spouse, it may be hard to identify the second stage, as the transition is smooth and accepting the increased burden is seen simply as part of the job of caregiving. The third stage is marked by nursing home placement or significantly greater external resources employed. For adult children this reflects a shift of caregiver burden to the nursing home or agency staff. For the spouse, the care of the impaired senior is reduced, but generally the need of considerable self-care begins. Like any other stage theory, the challenge of this sequence is to accurately identify when the caregiver is in transition between the three stages. However, this system offers an important alternative to that of anticipatory grief for persons working with families caring for a loved one who has dementia.

Grief and the Person With Dementia

Understanding the grief process of persons who have dementia can be even more challenging. It is important to note that persons with Alzheimer's or other related disorders do attempt to cope with the changes that affect their lives. This type of observation has been made by numerous researchers; however, until recently, little has been done to understand how grief affects the person with dementia. Communicating this type of experience for the person with Alzheimer's disease is limited by the patient's inability to articulate coherent feelings and then remember them for further dialogue. Based on the inconsistent cognitive capacity to process events such as the death of loved ones, it is understood that persons with dementia will vary in their response based on diagnosis and stage of the disease and even time of day.

In one recent study it was reported that persons who have dementia do experience grief at the time of a significant loss. However, it is often not expressed in ways that are consistent with normal grief responses. Three types of responses are identifiable. First, when family members inform the person with dementia about the death of a significant person like a spousal caregiver, the senior responds, not by articulating remorse for the loss, but by expressing concern for his or her own needs with a response like, "Well, who will take care of me now?" This type of self-care should be a part of every family member's response at some point, but usually the loss for self comes after the experience of the loss of the loved one. This type of subject-to-object reversal can be confusing, particularly for adult children who continue to perceive their mother or father as a role model for coping with their own grief process.

The second response is that of a person who seems to understand that someone has been lost, but simply cannot remember who. This person then becomes fixed on the death of a loved one such as a child or a parent who died many years earlier before the onset of dementia. In such cases, the person displays a genuine grief response specific to a person lost at a different time often putting them through, for a second time, a very painful experience that was processed many years ago.

The third response involves the transfer of the loss to an inanimate object. For example, the impaired senior may suddenly lose a pen, possibly one that family or other caregivers don't even know about, at about the same time as she or he is told of the death of a loved one. The senior is generally adamant that the pen is lost or stolen, yet no one is able to find the pen. The coincidental loss of the pen and the death of the loved one suggest that the senior understands that a loss has taken place, but simply has the wrong loss, fixating on the object, rather than the loved one.

Each of these three forms of grief should be understood as existing in a range of behaviors; however, the patterns are consistent. It is striking to now examine the reactions of the senior to that

of their family. When families realize some relief from caregiving for the person with dementia, the patient may confound the family in terms of their need to grieve. Preliminary evidence suggests that this can then lead to the rejection of a valid grief experience by the family.

Similarly, hospital staff, when confronted with what appears to be an inconsistent grief response, assume that it has no connection to the grief event. Thus any behaviors on the part of the senior with dementia that are out of the ordinary are viewed as problem behaviors and are often medicated rather than treated as a part of an authentic grief experience, different from that of the family or other expectations of normal grief.

In sum, the people with dementia, as well as their families, are confronted by numerous factors that can change even the expected patterns of response. Families, spouses, and seniors who have dementia all grieve with their own unique patterns and issues. Researchers and caregivers need to approach all three from the perspective of the stage of the dementia with the understanding that no one is immune from the feeling of grief. The difference is in how the individual manages and expresses grief.

Halloween

Halloween, celebrated on October 31, originally marked the beginning of the dark half of the year. Once tied to seasonal shifts and pastoral cycles in northwestern Europe, Halloween has always been seen as a portal for the spirit world. The imagery of Halloween is often the imagery of death—skeletons, corpses, ghosts—and Halloween's association with death and the spirit world can be seen in its Celtic mythological origins, its incarnation as a medieval church holiday, and its rendering in modern popular culture.

November 1 was once called *Samhain,* or summer's end, and marked the beginning of winter in the British Isles and Scandinavia. Samhain was first noted in Irish mythological sagas recorded by medieval monks as a time when demons were released, great kings slain, and sacrifices made. Fairy mounds opened to reveal the otherworld, and it was on Samhain that a magical fog lifted to reveal the dead. In 17th- and 18th-century Ireland, men returned from work abroad to spend the winter with their families on Samhain. The dead were so much a part of the Irish family that they would have been included in any reunion. People left out food and drink for them or kept an empty chair near the fire.

A series of medieval papal edicts instituted a church feast day to honor all saints that was eventually set on November 1 by Pope Gregory IV in 835. All Saints was known as All Hallows in Britain (*Hallow* meaning holy or one who is holy) and the evening before, as All Hallow's Eve, or Hallowe'en. Although Halloween owes its name to All Saints, it owes its association with death and the spirit world to the November 2 feast of All Souls.

Conceived around 1000 C.E. in the French monastery of Cluny and then set on November 2 by Peter Damian in 1063, the feast of All Souls was a time to pray for friends and family who had died. At the end of the 12th century, church liturgists emphasized the pairing of All Saints and All Souls feasts, sometimes called Hallowtide, to underscore how the living could hasten the journey of souls through purgatory. Saints, they taught, could intercede on behalf of the dead, and prayers or contributions could shorten a loved one's stay in purgatory. People came to believe that if this was true, then souls in purgatory could also return to haunt the living.

All Hallows was considered both a religious and an otherworldly time. Church bells rang throughout Western Europe to remember the dead. Italians in Naples opened charnel houses and dressed cadavers in robes for display. Halloween "guisers" (people dressed in monstrous costumes to resemble the dead) made a ruckus at court in 16th-century England, and in the countryside, bonfires blazed to ward off spirits. Some also carved turnips—representing souls trapped in purgatory—and went "souling" door-to-door or begged for small breads called "soul cakes" in return for prayers. The custom was common enough in Shakespeare's day that his character Speed (*Two Gentlemen of Verona,* first performed 1594–1595)

derides his love-struck master for "puling [whining] like a beggar at Hallowmas."

The Protestant Reformation condemned the idea of purgatory, as well as church holidays, as pagan or papist. Reform diabolicized ghosts and the Enlightenment of the 18th century gradually nudged supernatural beliefs into the realm of folklore and superstition.

Beginning as early as the 16th century, the first folklorists, called antiquarians, collected superstitions, ballads, and stories of the "peasantry" of the British Isles and beyond, fearful that old customs would be lost in the onslaught of a new industrial society. Halloween folklore, researched avidly in Britain, was used to enliven Victorian periodicals and almanacs, and to lend atmosphere or a rustic mysticism to the extremely popular literature of writers such as Robert Burns (1759–1796) and Sir Walter Scott (1771–1832) in Scotland, and William Butler Yeats (1865–1939) in Ireland. Generations of readers throughout Europe, Canada, and America came to know Halloween as a time when fairies could snatch babies, when the night sky grew thick with witches, or when a dead lover could return for a few sweet hours. By the turn of the 19th century, Halloween was widely acknowledged as the night one could glimpse the spirit of a future mate through fortune-telling tricks using apples, nuts, water, and fire.

In the late 19th century, anthropologist Sir James George Frazer proposed his theory that folkways were vestiges of pagan practices, and that Halloween originated in a festival of the dead. Frazer argued that the church placed its All Saints and All Souls feasts on November 1 and 2 to supplant pagan rites. Contemporary historian Ronald Hutton suggests it's just as likely that what Frazer and others recorded as the remnants of ancient beliefs were really half-remembered Catholic teachings.

Contemporary Halloween costumes still conjure the dead (skeletons, bleeding zombies, serial killers), as does Halloween imagery (tombstones, corpses, bones), but this modern association with death is now more rooted in popular culture than folklore. Films such as the seminal 1978 John Carpenter film *Halloween* recast the holiday as darkly evil, and a new popular literature emerged in which Halloween's relationship with the dead was mined for horror. In the late 20th century, stories of death by poisoning and razor blades in Halloween treats made headlines, although further research proved them to be hoaxes or urban legends.

Modern-day pagans, who practice an earth-based spirituality, mark Halloween as a time to honor the memory of the dead. For all other celebrants, the otherworldly elements of Halloween have moved into the realm of fantasy, satire, and entertainment, making Halloween one of the 21st century's most creative holidays.

Halo Nurses Program

The Halo Nurses Program involves retired registered nurses (RNs) who give supportive care to hospitalized patients and families in the midst of crisis situations that may include terminal illness and end-of-life concerns. Halo Nurses serve at Akron General Medical Center (AGMC) in Akron, Ohio, and are supported by the Akron General Development Foundation.

History

Eileen Machan, RN, began the Halo Nurses Program at Cuyahoga Falls General Hospital soon after her retirement in 1996. She had observed the increasing work pressures and constraints on nursing staff in acute care settings and recognized that the supportive, listening, comforting aspects of care often had to be minimized due to time constraints. Ms. Machan and several other nurses visited patients and families who were referred by

nurses or physicians with a focus on therapeutic listening. Patients and staff found the work of the Halo Nurses to be effective. Additionally, the nurses themselves were able to use their extensive nursing experience to provide support and encouragement to patients and families and had the satisfaction of helping others.

Though the Halo Nurses were essentially volunteers, they were given a small stipend to compensate for travel, continuing education, and liability insurance. This was provided through the Halo Foundation, Inc., a nonprofit group. The hospital did not pay the nurses for their visits.

In 2001, Jon Trainor, President of Akron General Development Foundation, asked Ms. Machan to move the program to AGMC. Halo Nurses initiated the work on two medical/surgical units and one oncology unit. Since then they have been available on other units throughout the hospital. They continue to receive a stipend to cover expenses but no salary.

Mission and Purpose

Halo Nurses focus on assisting patients and families dealing with a variety of health care crises. According to the *Halo Nurses for Supportive Care* brochure, the goal is to offer care "that complements traditional medical care by providing patients the physical and psychological tools to deal more effectively with stress and pain of serious illness." The nurses have strong clinical care backgrounds that give them skill in assessing situations and how they may help. In addition, they are specially trained in using therapeutic listening, relaxation techniques, guided imagery, and healing touch. They do not give direct nursing care, such as medications or other therapies, but may reposition a pillow, give a back rub, or give other comfort care as approved by the staff. The nurses are to supplement the medical and nursing care that is being given, not replace it.

Referrals for Services

Nurses, physicians, and other members of the health care team refer patients and families. Halo Nurses have an office at the hospital with voice mail so that referrals may be received. A Halo Nurse then responds and makes an initial visit. The recipients of care are those who are dealing with stressful situations and who may benefit from the listening ears and comfort measures offered by the Halo Nurses.

Qualifications of Halo Nurses

Halo Nurses are retired or are not currently in active nursing practice. They are required to have a current RN license to practice in the state of Ohio and current nursing liability insurance. They must have a strong clinical background, strong spiritual grounding, and experience in holistic nursing modalities such as relaxation techniques. They have to verify that they have read and agree with the Halo Nurses' Code of Ethics and Standards of Practice. Additionally, they commit to attending at least one seminar yearly pertaining to holistic care. The Halo Nurse Coordinator holds monthly meetings with the nurses to assure continued excellence of the program and also determines the need for additional nurse consultants.

Provision of Services

The Halo Nurses are available Monday through Friday during daytime hours, though occasionally someone will come in the evening to better meet the needs of patients and families. Each day, two or three nurses work 4 to 6 hours at a time. The nurses usually work 1 to 3 days a week. When a referral is received, a Halo Nurse goes to the hospital unit, reviews the patient's chart, and spends an average of 45 minutes with the patient listening and determining supportive care that might be offered. The nurse then charts the visit on the appropriate forms so that the medical and nursing personnel are aware of the visit and the Halo Nurse's involvement in the supportive care of the patient. Halo Nurses usually devote their time to patients with high anxiety or hard to manage pain. The patients may be facing a serious diagnosis or may be in a deteriorating or terminal state due to cancer or other serious illness. The Halo Nurses also make regular rounds on medical/surgical, oncology, and perinatal units where the charge nurse may ask them to visit a patient in need of a "listening ear." The patient is frequently the focus of the work of the Halo Nurses, but a family member may also be referred to receive

emotional support and help in dealing with the stresses of being a caregiver.

Benefits of the Program

The Halo Nurses Program is a model for providing needed therapeutic interventions that may go missing for patients and families in a busy hospital environment. At AGMC, the staff, patients, and families consistently give positive feedback for the program. The hospital has received high patient satisfaction scores in recent years, and leaders give some credit for that to the Halo Nurses Program. The Halo Nurses themselves also benefit by being able to continue using their considerable nursing backgrounds and interpersonal skills to serve patients and families facing health care crises.

Hate Crimes and Death Threats

Hate crimes, also known as bias crimes, are crimes against people, property, or society that are motivated, in part, by a bias against real or perceived characteristics of the victims. Hate crimes include a wide array of criminal offenses, such as murder, death threats, church burning, theft, and vandalism. Statutory definitions of hate crimes vary in the number and victim characteristics specified, but generally include race, religion, and ethnicity/national origin. Sometimes disability, sexual orientation, gender, transgender/gender identity, political affiliation, and age are included as protected classes, although whether to include some of these has been controversial at times. In some cases, hate crime legislation requires data collection, training for law enforcement personnel, and provisions for sentence enhancement for offenders. Hate crime legislation also allows for civil action. The criminal category of hate crimes has both supporters and opponents.

Although the legal category of hate crimes is relatively new, violence, death threats, and other crimes motivated by hatred of particular characteristics of the victims are not a recent phenomenon, nor are these actions limited to the United States. Jews, Tutsis in Rwanda, Protestants and Catholics in Northern Ireland, immigrants and refugees in Sweden and Italy, civilian members of the Fur, Zaghawa, and Massaleit ethnic groups in Darfur, Aboriginal people in Australia, and Mormons are examples of groups that have been targets of violence because of their ethnicity, race, or religion.

Hate Crime Laws

Lynching, cross burning, death threats, intimidation, and other forms of violence against African Americans, most notably by the Ku Klux Klan, were so common after the Civil War that the federal government responded, in part, by passing the Civil Rights Act in 1871. Approximately 100 years later, the first federal law to specifically mention characteristics of the victims was passed because of the bias-motivated crimes that garnered national attention during the civil rights movement. This law granted federal authority to investigate and prosecute those who use force or threats of force to willfully injure, intimidate, or interfere with someone because of the victim's race, color, religion, or national origin when he or she was attempting to engage in federally protected activities, such as attending school, being employed, traveling, and securing lodging.

In the 1980s, groups that advocated hate against marginalized groups, particularly African Americans, gays, lesbians, and Jews, became more visible. The use of the term "hate crimes" became associated with some actions of organized hate groups, such as the Confederate Hammerskins (racist skinheads),

League of the South (neo-Confederates), Americans for Self Determination (white nationalists), Victory Nights of the Ku Klux Klan, and White Revolution (neo-Nazis). Hate groups continue to proliferate. In 2007, the Southern Poverty Law Center identified 888 active organized hate groups, which is 48% more than in 2000.

In 1990, Congress passed the Hate Crime Statistics Act (HCSA) requiring the Attorney General to gather and make available to the public data about crimes motivated by prejudice based on race, religion, sexual orientation, or ethnicity. In 1992, the Uniform Crime Reports included data on hate crimes for the first time. Two years later, Congress passed the Violent Crime Control and Law Enforcement Act that expanded the requirements of the HCSA to include hate crimes against people with disabilities.

According to the Anti-Defamation League, all states and the District of Columbia (DC) have criminal penalties for bias-motivated violence and intimidation, except Arkansas, Georgia, Indiana, South Carolina, and Wyoming. Combining state and DC laws, 45 include race, religion, and ethnicity, 31 include sexual orientation, 31 include disability, 27 include gender, 22 include religious worship, 13 include age, 10 include transgender/gender identity, and 5 include political affiliation.

National data on hate crimes are primarily generated by the Uniform Crime Reporting (UCR) Program and the National Criminal Victimization Survey (NCVS). These two sources paint a considerably different picture of the frequency of hate crimes, with the NCVS data indicating that hate crimes are considerably more common than captured in the UCR data. According to UCR data, in 2006 there were 7,722 hate crime incidents, 9,080 offenses, and 9,652 victims that included individuals, businesses, institutions, or the larger society. A bias crime against the victim's race/ethnicity was the most common motivation, followed by sexual orientation and religion. From 2000 to 2003, NCVS data indicated an annual average of 210,000 hate crime victimizations and 191,000 hate crime incidents. Of these totals, 84% were violent crimes.

Death Threats and Murders

In some states, when a death threat is made against a member of a specified group, the threat can be considered in determining whether a hate crime has been committed. As with hate crimes, what constitutes an illegal death threat is a complex legal issue, often linked to First Amendment rights. In general, a death threat is not protected speech if there is intent to follow through with the threat. Other factors are considered in determining an unlawful death threat, such as the context in which the threat occurred and whether the target is fearful of serious harm. The means by which an illegal death threat can be communicated include speech, telecommunications, mail, e-mail, and the Internet.

Since 1996, 118 murders were classified as hate crimes. UCR data indicate that the some murders were motivated because of a bias against the victim's race or ethnicity—white (19%), black (27%), Asian Pacific (5%), Hispanic (14%), and multi- or other race (7%)—and others because of the victim's religion (4%), sexual orientation (22%), or mental disability (1%).

Two savage murders illustrate the types of violence associated with some hate crimes that have helped garner public and political support for hate crime legislation and enhanced sentences. Three white men picked up James Byrd Jr., a black man, while he was hitchhiking in Jasper, Texas. Driven to a rural dirt road, he was severely beaten, and then chained by his ankles to the rear bumper of the vehicle. The men dragged Byrd for several miles. Police discovered Byrd's torso on the road and followed a trail of blood that led to Byrd's head and arm in a ditch, approximately one mile from where his torso was located. Byrd's attackers were white supremacists.

In another murder, two men, on the pretext of a sexual encounter, lured Matthew Shepard, a college student in Wyoming, from a bar. The men then robbed, pistol whipped, and tied Shepard to a fence, where he was left to die. Shepard remained there for approximately 18 hours in near-freezing temperatures before a passerby discovered him. Matthew Shepard died 5 days later because of the severe brain damage inflicted by the men who were offended by his homosexuality.

Sentencing Enhancement

One of the most controversial features of hate crime laws is sentencing enhancement. The Hate Crimes Sentencing Enhancement Act required the U.S.

Sentencing Commission to increase sentencing by at least three offense levels for offenders who were found guilty of a federal crime in which the victim was targeted because he or she belonged to a group specified in the federal hate crime laws. State laws relating to sentencing enhancement vary. For example, some laws require that an enhanced sentence be added to the sentence that would be given if the crime were not classified as a hate crime, while others only enhance the sentence for particular hate crimes, such as assault or property damage.

Support and Opposition to Hate Crime Legislation

One argument made by proponents of hate crime laws is that hate crimes lead to greater psychological and physical harm than other crimes, with the harm extending beyond the victim to the victim's family, other members of the target group, and society at large. Another reason given for support of hate crime laws, particularly with enhanced penalties, is that they deter potential offenders, although the evidence that supports this claim is weak. Frequently articulated arguments are that these laws have important symbolic value by articulating and reinforcing the principle that all citizens should be allowed equal participation in a democratic society and that hatred that is translated into action against members of protected groups will not be tolerated. For supporters, the issue is about justice and security for targeted groups and is not about special rights to some citizens over others. Some posit that hate crime laws prevent large-scale retribution by members of the victim's protected class that otherwise might occur if there were no legal recourse. Those who are in favor of hate crime laws stress that the laws are not designed to curb free speech granted in the First Amendment. Rather, they say that hate crime laws allow legal recourse for speech that is not already protected by the Constitution. Further, proponents note that considering the motivation is already done in criminal proceedings, so taking into account the motivation for hate crimes is not beyond the boundaries that are currently being practiced.

Those who are opposed to hate crime legislation frequently argue that these laws are not needed because the crimes included in hate crime statutes are already criminal offenses. In contrast to supporters of the laws, opponents posit that empirical evidence is lacking for the claims of increased harm and that most hate crimes are relatively minor in spite of the high profile cases. Opponents argue that the laws reflect identity politics and political influence of groups, such as women's rights and gay liberation movements, rather than addressing real problems. They assert that free speech is being increasingly violated as hate expressed through e-mail, the Internet, and other non-face-to-face communications are being considered illegal under hate crime laws. A major concern is that hate crime laws prioritize some victims over others, to which supporters respond that this is already being done, such as when killing a police officer is a capital crime in some states when other murders are not. Those who argue that hate crimes are not needed state that there is no evidence that hate crime laws will improve intergroup relationships. Opponents are also concerned about what they see as the proliferation of protected categories, such as the recent inclusion of transgender people by some states, and believe that the laws are too vague to be enforced. Another argument is that the enhanced sentences associated with some hate crimes only increase the already overburdened prison system.

Heaven

Heaven is one the cardinal representations of life after death. Even outside conventional religious circles, the image of the dead sojourning in heaven is popular. Generally speaking, heaven is a metaphor for another world distinct from the here and now. It is a transcendent sphere beyond the immanent world, yet observable from the here and now. Among the connotations of heaven, the first to be discussed is a cosmological meaning of heaven. Second, there is the religious meaning of heaven; Heaven in the sense of a divine world and the place where the dead dwell. Connected to this, there is hell, being the antipode of heaven. Besides this religious meaning, heaven symbolizes the consummation of the world at the end of time. Finally, in modern thinking, we find a new, more immanent meaning assigned to heaven.

The Cosmological Meaning of Heaven

Heaven has a cosmological meaning. It is part of the cosmos in which human life is conducted. It is the uppermost part of the cosmos and, in addition to its natural meaning, may have a religious or spiritual connotation. People on earth have always raised their eyes heavenward and sought to understand what they saw. In the past, heaven was regarded as the upper limit of the world. At a certain point vision ends, and this limit was interpreted as heaven. An example is the ancient Eastern worldview. In this view, the world was perceived in three parts. At the bottom was the primeval flood, representing chaos; in the middle was earth, where people lived; and finally, heaven was located at the top, above the earth. In the observable space where life took place, according to this worldview, heaven constituted the visible, spatial boundary of earth.

Modern scientific development changed this perception of heaven. People could travel to heaven, discover stars and planets, and literally come to grasp that the cosmos is vaster than what is visible from earth. This new human ability to explore the cosmos altered the meaning of heaven as a limit. In fact, the focus was now on the boundlessness of the heavens. This shows how dependent people's image of heaven is on their cultural context and worldview.

Besides this spatial meaning of heaven as part of the cosmos, it can have a spiritual meaning as well. This often relates to the stars. By ascribing certain spiritual forces to the stars, heaven's cosmological reality influences life on earth. There is a link between heaven and earth. Here, the relation between astronomy and astrology is pertinent. Astronomy is the science that seeks to improve observation of the heavens and the study of stars. Astrology, on the other hand, is a system of meanings attributed to the stars and the heavens. In this perspective, life on earth is directed from the heavens. In these two areas, we find, on one hand, scientific insight into the stars, and on the other, mythological interpretive patterns such as constellations that can be used to understand individual human lives. In both perspectives the stars exercise a powerful fascination. The part of the cosmos that lies beyond the human life world signifies transcendence of the life world. It also permits people to interpret death: Cosmologically heaven symbolizes human life as part of a larger whole in both an observable and a mythological sense. This may be associated with the notion that death is not the final limit of human existence.

The Religious Meaning of Heaven

Heaven also has a religious meaning. In religions it often symbolizes the divine. Heaven is seen as the divine world transcending the here and now. It is the abode of God or the gods—sometimes of angels and other supernatural beings as well. This makes heaven a transcendent, divine form of

existence inaccessible to human beings. In the Abrahamic religions we find concrete representations of heaven, such as paradise. This was where people lived after creation and from which they were driven as a result of sin. Paradise is guarded by angels, who see to it that this abode of God is preserved for people whom God takes into heaven. Islam represents heaven as a luxuriant garden where rivers of wine, milk, honey, and water flow. This, too, has connotations of a paradise, where the limitations of earthly life do not apply. To human beings, this place is inaccessible.

Yet people have always tried to gain access to heaven and to establish contact with it even while living on earth, for instance by way of ecstatic practices. One example is shamanism. A shaman is someone who can make contact with another world beyond normal human perception. Through rituals a shaman is able to communicate with spirits belonging to the celestial realm. In the Abrahamic religions, mysticism is a way of knowing heaven even before reaching paradise. Mystics are able to form an idea of what divine reality in heaven represents.

Christianity adds a further dimension to the notion that people can share in heaven even while they are still on earth. After his death, resurrection, and ascension, Jesus Christ assumed the place at the right hand of God the Father. Because Jesus, a being both human and divine, occupies this focal position in heaven, heaven is conceivable and accessible to Christians. Their relationship with Christ becomes the way to heaven where God sits. It also has an ethical connotation: At the behest of heaven people ought to live righteously as Christ has commanded them. In Christian terms, solidarity and love of others makes it possible to experience heaven while still on earth.

Connected with the religious meaning of heaven, it has also meaning for the dead. As an extension of the religious meaning of heaven as the domain where God and the angels rule, heaven acquires the meaning of a place for the dead. In many cultures, heaven connotes a home for humans in a transcendent sense: They are descended from preexistent soul, and the souls of the dead can then become, for example, ancestors. That implies that people on earth are descended from heaven and will return there after death. According to ancient Egyptian belief in immortality, the deceased leaves the grave, goes to heaven, and dwells there among the gods. Thus, the lid of the coffin symbolizes heaven because heaven is reached via death. For concrete representations of the place that the dead occupy after death, the aforementioned images of paradise are vitally important. They also determine how heaven that awaits one after death influences one's earthly life. Here the ethical connotation of righteous conduct in this life is pertinent. Heaven is where those who led righteous lives end up.

The antipode of heaven is hell. This is where people end up if they did not live righteous lives. Like heaven, there are concrete representations of hell in many religious traditions, including Christianity. In Christianity, hell is the abode of fallen angels (Lucifer) and demons who turned away from God. People who go to hell after death endure great suffering, such as burning in eternal fire. Decisive for many portrayals of hell is the aforementioned cosmological image of heaven as somewhere above, and hell as the realm below. According to these representations, good souls go above and bad ones below. In the Middle Ages, the Christian tradition saw the addition of the image of purgatory as well. This is a kind of intermediate state for people who have to do penance for sins committed in their lifetime. Unlike the dead who end up in hell, they have a chance of reaching heaven after a period of punishment.

There are many literary portrayals of these three components of the hereafter: heaven, purgatory, and hell. A famous example is Dante Alighieri's epic, *La divina comedia* (The Divine Comedy). In this work, the poet describes his journey through the hereafter: *inferno* (hell), *purgatorio* (purgatory), and *paradiso* (paradise). Here the religious interpretation derives, as noted already, from a cosmic worldview. In Dante's Ptolemaic worldview, half of the earth is inhabited, the other half is sea. Hell is inside the globe and originated when God cast the angel Lucifer from heaven. Purgatory is a mountain in the middle of the sea. Heaven consists of nine circles or spheres girdling the earth. The dead can eventually reach these via the mountain of purification, which corresponds with purgatory. This imaginary world exemplifies the way people attempt to give a plastic portrayal to the form that life after death may assume. The Islamic version of heaven comprises seven layers. According to Islamic doctrine, those who reach

heaven after death are waited on by virgins and youths. This is another way of portraying the paradisial nature of heaven for the dead.

Eastern religions offer a different perspective. In these traditions, people do not believe in eternal life after death but in reincarnation or rebirth. In this view, heaven, hell, and purgatory do not exist. What is known is heaven is not an eternal sojourn, nor is it a final consummation at the end of time. In Buddhism there are various heavens in which people who have lived righteously and earned good karma are reincarnated as a kind of god (*deva*). In due course, however, this heavenly period comes to an end; the deva dies and is reincarnated once more until nirvana is reached as the final state.

Heaven as Consummation of the World

Heaven represents the consummation of the world. Apart from being the destiny of individual people, heaven also connotes the destiny of humankind collectively and the whole world. It is the fulfillment of humanity and the earth's relationship with God in the end time (Eschaton). In Judeo-Christian terms, this relationship starts for individuals during their earthly lifetime, and for the earth it started at the time of creation, but it is only fully realized by coming face-to-face with God in heaven on the day of the Final Judgment. People will fully experience what started on earth when the end-time dawns. Then the graves of the dead will open, and they will stand before God's throne of judgment. The good will go to heaven forever. The notion that this happens at the end of time is also featured in Islam. In Islam, the dead pass through a phase of sleep after death. They are only judged by God much later, at the end of time. Judaism, Christianity, and Islam all see heaven as a final state to be achieved one day.

The Immanent Meaning of Heaven

In modern thought, heaven has acquired a new, more immanent meaning. Often it is depicted as a further dimension of earthly reality rather than a concrete place. Ever since the Enlightenment, thinkers—including religious thinkers—have focused on the here and now rather than on some place beyond earthly reality. The worldview has changed to the extent that heaven is no longer conceived of as primarily in a spatial sense. Yet in this context, thoroughly new utopian images of heaven have emerged. In modern scientific thinking, heaven is interpreted as the essence of everything that humans can achieve by harnessing the limitless potential that nature and the cosmos offer.

Currently there appears to be fresh interest in heaven. For instance, it is evident in modern art, which seeks to express the transcendent. Also in people's experience of bereavement, heaven plays a major role. Research into obituary notices shows that people derive hope from the idea that they will see their loved ones again in heaven after death, and that their loved ones have a place in heaven, from where they watch over and help the living in their lives.

Hell

Hell, in its most pervasive theological sense, refers to the state of eternal suffering after death. Hell has also been conceived as a place in which such suffering is endured or inflicted. The contrasting concept, heaven, is usually taken to mean an endless postmortem state of supreme joy and blessedness. In both Christianity and Islam, the blessedness of heaven is associated with the direct experience of God, what Christians call the beatific vision. Hell, by contrast, involves alienation from God. The doctrine of hell is the belief that at least some

people, after death, endure hell. While this doctrine is primarily associated with Christianity, other religions have parallel or related doctrines.

Many religious scholars believe that Zoroastrian influences played a crucial role in the formation of Christian ideas of heaven and hell. In mature Zoroastrian theology, however, hell was not conceived as an eternal state, but as one that would persist until the end of history, when the final defeat of Angra Mainyu (the Zoroastrian devil) by Ahura Mazda (the Zoroastrian god) would also bring about the salvation of the damned. The Zoroastrian doctrine demonstrates that although hell is usually thought of as an eternal or everlasting state (and while this has certainly been the dominant view in the history of Christianity), it can be conceived as temporary.

The focus in this entry is on the Christian doctrine of hell. Within Christianity, this doctrine has two important rivals: the doctrines of universalism and annihilationism. Universalism holds that, ultimately, all people are saved. Interestingly, universalism is consistent with belief in a hell similar to the one endorsed in Zoroastrian theology—as a state of suffering that endures, perhaps for a long time, before culminating in salvation. Historically, Christian Universalists have tended to accept the existence of something like hell—that is, intense postmortem suffering among those who die rejecting God. But they conceive such suffering as serving a reformatory purpose, ultimately contributing to the salvation of the sufferer. In the theologies of such seminal Christian Universalists as Origen and Gregory of Nissa, the "fires" of hell are thus taken to be purging fires.

Views of Hell

Annihilationism more decisively rejects hell in favor of the view that those who die unregenerately are utterly destroyed, and thus experience neither suffering nor pleasure. Annihilationism shares with the doctrine of hell the idea that those who die unregenerately are subjected to eternal punishment, and that there is no possibility of salvation once the punishment is imposed. But it denies the claim that God would subject the unregenerate dead to eternal suffering.

Among these alternatives, the doctrine of hell has the status of orthodoxy. But this doctrine itself comes in different forms. The classical doctrine of hell holds that damnation results from an act of divine justice. That is, God imposes the sufferings of hell on the damned as a just punishment for sin. And the afflictions of hell involve not just loss of the beatific vision and all goods that go with it, but also positive bodily and psychological pains inflicted by God for punitive reasons.

On this view the damned, by sinning against God Himself, come to deserve the worst evils that it is possible to inflict. Following Saint Anselm, most defenders of the classical doctrine have argued that because God is infinitely good and deserving of unlimited praise and worship, those who sin against God commit a sin of infinite severity, and thus deserve a punishment that is likewise infinite. Eternal suffering of the worst sort is therefore demanded by justice. God, motivated by justice, metes out precisely what sinners deserve.

Some classical Christian thinkers have even sought to enumerate in detail the kinds of sufferings that God imposes on the damned, distinguishing between afflictions of body and those of the soul, and between afflictions that are simply the result of being deprived of the vision of God and those that are imposed by God as a further punishment for sin. A few classical theologians have made the interesting point that, based on Christian value oriented assumptions, the worst affliction that anyone can suffer is not bodily or psychological pain, but sin itself. And so, if the damned deserve to have the worst possible afflictions imposed on them, God would need to ensure that they remain forever wicked, because being wicked is in itself a far worse fate than any further affliction that accompanies it.

According to this classical view, God is the immediate cause of damnation and its attendant sufferings. Furthermore, hell is not treated as a regrettable evil, but as a positive good. Some classical Christian thinkers, most notably Saint Thomas Aquinas, stated explicitly that the damnation of the wicked is a fact to be celebrated. According to Aquinas, witnessing the sufferings of the damned would actually magnify the delight of the blessed in heaven, who would rejoice in the just punishment of unrepentant sinners.

Many issues are related to this classical doctrine of hell. Some analysts have argued the doctrine of hell comes into conflict with other doctrines

pertaining to God's nature, especially His benevolence, while others identify tension between such benevolence and the Christian doctrine of the Atonement (i.e., the doctrine that Christ fully satisfied the demands of justice for human sins on the cross). While theologians in the past have sought ways to surmount these conflicts, contemporary defenders of the doctrine of hell favor setting aside the classical version in favor of an alternative.

According to a more liberal contemporary doctrine, hell is not a punishment for sin but a natural consequence of freely choosing to reject God's gracious offer of loving communion. The sufferings of hell are taken to involve nothing other than what necessarily follows from this free rejection of God. God, instead of imposing the sufferings of hell as a punishment, permits them out of respect for the free choices of the damned.

On this view, the damned are those who choose for all eternity to reject God's love, and the suffering of hell is nothing other than the experience of being deprived of every good that comes from union with God. Some contemporary religious thinkers, elaborating on elements of Dante's vision of hell, believe that such a state need not be as horrific as hell is ordinarily taken to be, because certain natural human pleasures, such as interesting conversation with others, might still be available to those who are alienated from God. Others, however, argue that alienation from God is alienation from the source of everything that gives interest and value to life, and is thus a state of total bereavement and anguish. Another concern is that the choice to reject the source of all that is good would only be made by those who suffer from a serious character flaw that, in the course of an eternal existence, would fundamentally compromise psychological health, leading eventually to the most debilitating inner torment.

Competing Doctrines of Hell

The most significant challenge for defenders of the liberal doctrine is to explain what could motivate the choice to eternally reject God's love, even though that choice supposedly brings only misery. While defenders of the doctrine cite pride or willful self-deception as playing a crucial role in such a choice, critics argue that no such motives could lead one to reject God's love forever, at least given the view that alienation from God is unremittingly and inconceivably horrible. Put simply, no one would choose the outer darkness if they really knew what they were choosing, and if they were truly free not to choose it. So if anyone is forever damned, it is difficult to make sense of how it could be purely a matter of free choice.

Some religious scholars argue that Christian theology as a whole makes no sense without a doctrine of hell. Unless there is a hellish fate to be saved from, the promise of salvation offered within Christianity loses its meaning. But this worry is largely vacuous. If a rescue team saves everyone from a sinking ship, the rescue has meaning even though all are saved. What gives it meaning is not that some are not rescued, but that many or all would have drowned without the rescue effort. Likewise, all that is needed to give meaning to Christian theology is a hypothetical hell, not an actual one: If human beings would suffer eternal alienation from God except for God's redemptive effort, this effort has meaning even if no one suffers such alienation. In fact, the redemptive effort becomes more impressive if it is universal in scope.

One of the most interesting issues pertaining to the doctrine of hell may be the impact that belief in this doctrine has on the living and the dying. At least one argument on behalf of the doctrine of damnation is that it encourages people to take moral norms and spiritual practices seriously in this life and to more fully appreciate the gravity of immorality and blasphemy and the urgency of moral reform. There is no doubt that the doctrine of hell has been invoked historically as a reason to diligently abide by the moral and religious teachings of Christianity (or an alternative faith as the case may be). A similar idea may apply to the dying: The prospect of damnation may motivate those who are vividly conscious of their mortality to seek to redeem their gravest failures in their final days.

However, it is debatable whether the doctrine of hell has these pragmatic benefits. Some clergy have noticed that the gravity of what the doctrine of hell promises is more likely to inspire either despair or denial and disbelief. The classical doctrine, in particular, has inspired hostile reactions through history, and is frequently cited by atheists as a reason for rejecting religious belief. Liberal theologians tend to point out that the image of a

wrathful and punitive God is more likely to inspire cowering servility or enmity than to inspire love and trust. If the aim is not merely to generate outwardly moral behavior but an inner attitude of loving devotion to God and His creation, it may be more effective to encourage feelings of gratitude rather than fear.

These last concerns may be partly avoided by the liberal doctrine of hell, which eschews the image of a wrathful God who punishes the unregenerate dead. But even in the case of the liberal doctrine, the gravity of what is purported to hinge on our free choices may have negative pragmatic effects. If avoiding damnation lies in one's own hands, one might be motivated to do one's best to make sound choices; but if a shattered self-esteem makes one skeptical of one's capacity to make such choices, the dire consequences that the doctrine of hell promises as the cost of failure may inspire despair.

Hindu Beliefs and Traditions

Reincarnation is the archetypical belief and cremation is the archetypical practice for death among Hindus throughout India. This has been so for centuries, if not millennia. David Knipe explains the link between the belief in reincarnation and the practice of cremation. In one complete round of rebirths, the *Atman* (soul) makes five transitions, five being arguably the most sacred number in the Hindu worldview just as three holds that place in the West. The Atman travels from sky to earth by rainfall, from plants to men, from men to women, from women to bodily form, and by way of cremation back to the sky to begin the process anew. This account of reincarnation and the relevance of cremation to that process illustrate the holistic nature of the Hindu worldview in which humans are within the cosmos but are not viewed as having either the power or the right to fully control either their individual destiny or the environment.

The earliest references to Hindu death rituals are found in the *Rig Veda* and *Atharva Veda,* the Vedas being the oldest continuously used religious texts in the world. More detailed accounts are found in the *Garuda Purana*. In broad terms, the guidelines in these texts continue to be followed. However, there are also departures from those guidelines that reflect the passage of time and regional and local culture. Caste, stage of life, gender, and other factors, such as level of prosperity and makeup of the household of the deceased, also bear on the performance of death rituals. For example, someone whose job or income does not allow for him or her to perform the full set of rituals is not expected to do so. However, while some observers find no fault in such behavior, others may attribute any subsequent misfortune suffered within the family to failure to properly honor the deceased.

With regard to death rituals, the principle of *varna-ashrama-dharma* (caste stage of life-duty) is especially evident in the disposal of the dead by means other than cremation for certain categories of people. Corpses of young children and of *sadhus,* or holy men, are to be buried because they do not require the purification provided by *Agni* (fire both as a form of energy and as a form of god). The corpses of victims of epidemics or snakebites

are to be lashed to a bamboo stretcher and placed on a river, ideally the Ganges (a.k.a. Ganga). Explanations for these departures from cremation vary. By not burning the corpse of one who has died of disease, family members are said to avoid courting the wrath of the evil spirits who caused the person to die. By not burning the body of a snakebite victim and instead placing it in the care of Ganga, there is the possibility that the goddess Ganga might restore life to the individual.

Shraddha (Death Rituals)

Hindu death rituals serve the needs of both the dead and the living. For the recently deceased, the rituals remove pollution and facilitate the journey to *Yama,* Lord of the Dead, and to the next bodily form in this world. For the living, the rituals serve to remove the pollution they face on the death of a family member and help them to achieve peace of mind. In a larger sense, for all concerned, the rituals work toward restoring the balance that was disrupted by death.

As a family member approaches death, he or she should be placed to face east, the direction of the rising sun. Ideally, a dying person is given Ganga water from a *tulsi* leaf. Shortly after death, family members wash the body and place it in new cotton clothes, normally white. A woman who dies before her husband may instead be wrapped in red cloth, which symbolizes that she is married and was fortunate to die before being widowed. The thumbs of the deceased are tied together and so are the big toes; this prevents the limbs from shifting while the body is being taken to the cremation grounds. After receiving new clothes, the body is placed on the ground facing south, toward the abode of Yama. The family's *purohit* (Brahmin household priest) comes to the home, recites mantras, and lights an oil lamp at the head of the body. The lamp is kept burning throughout the mourning period.

A chief mourner, known as *dahak,* most often the eldest son of the deceased, performs rituals throughout the mourning period, which for higher castes is generally for 13 days. Custom allows for others to serve as dahak, depending on the makeup of the family. In principle, lower castes require longer periods to overcome the pollution brought on by death; however, their economic circumstances generally preclude lengthy and expensive rituals.

Cremation occurs within 24 hours of death. Before the body is taken to the cremation grounds, the dahak's head is shaved signifying that he is in mourning. In some instances, other men and older boys of the family may also have their heads shaved at that time. Traditionally, only men go to the cremation site, but nowadays sometimes women also attend. The dahak leads the way carrying a clay pot with burning incense. The mourning party carries the corpse overhead on a bamboo stretcher chanting *Ram nam, satya hai* (Ram is truth).

Before being burned, the body is taken around the funeral pyre counterclockwise three times. It is then placed on the wood and more wood is added to cover all but the head. The corpse is then given offerings of incense and ghee (clarified butter). The dahak, carrying a clay pot with water, makes three counterclockwise rounds of the site, and then throws the pot on the ground, breaking it. Then, without turning to face the body, he lights the pyre. To do this, he takes instructions from the *Dom* (low caste funeral priest). When the body is nearly cremated, using a long heavy bamboo rod and at a moment indicated by the Dom, the dahak breaks the skull. This act is known as *kapal kriya* (the rite of the skull). This is done in order to release the Atman (self). Nowadays, with the growing acceptance and use of electric crematoria, this ritual is slowly disappearing. (See further text for more details on Doms.)

After returning home, the mourners take a purification bath. In the place where the body was kept, an oil lamp is lit and kept burning to light the way of the departed soul. On the next day, the mourners return to the site to gather the "flowers" (remaining bits of bones and ashes), which they later deposit in a river, ideally the Ganges, so that these remains might be carried out to sea and the deceased will be in position to be reborn.

Throughout the mourning period, family members remain polluted and, in their impure state, various restrictions apply, especially to the dahak. He is to sleep on the ground and does not leave the home except to perform other *shraddha* rituals. During the mourning period, cooking within the home is forbidden; the family eats only pure, or *satvik* (vegetarian and without onion or garlic) food brought in from outside the home. During the days of impurity following a death, it is customary for the family to eat foods especially liked by the

deceased and to offer *pindas* (rice balls) to three or more generations of the ancestors, with particular emphasis on male ancestors. Additionally, in many households, during their days of pollution following the death, the family members bathe in water but without using soap, and they do not clean the house. The men do not shave or cut their hair, and family members do not cut their fingernails or toenails. After a death as well as a birth, married individuals, polluted by either the arrival or departure of a family member, avoid worship of the gods until a prescribed number of days (typically 12) have passed.

On the day after cremation, the dahak is joined by another funeral priest known ironically as *Mahabahmin* (Great Brahmin), also known as *Mahabrahmin* and *Mahapatra*. Understood to belong to a branch of Brahmins who disgraced themselves in the distant past, the Mahabahmin performs only certain death rituals and does not serve on other occasions. He and the dahak perform *pinda daan* (feeding ancestors with rice balls) and place a clay pot with a small hole in the bottom in a pipal tree on the outskirts of the inhabited area. This ritual is known as *ghant bandhana* or *ghant matkana* (to tie the pot and to hang the pot). *Ghant* literally means "Adam's apple." The dahak returns daily through the 10th or 13th day to fill it with water. The *prêt* (unsettled spirit) retains some bodily needs, including need to quench its thirst, during the shraddha period. However, lacking bodily form, it cannot alight on the ground or a body of water to drink. The water dripping from the clay pot serves its needs. At the conclusion of these rituals, the Mahabahmin decides when the prêt no longer needs water and instructs the dahak to break it using a sturdy bamboo pole. This is regarded as a potentially dangerous task. This is because the prêt depends on the dahak and Mahabahmin; if the rituals are not performed in a timely manner, the prêt may become angry and attack either of these individuals. On the last day, for his services, the Mahabahmin is given cash as well as many of the possessions of the deceased, such as the cot, clothes, and sometimes more valuable items, but not possessions of sentimental value.

The 10th day marks the end of the family's pollution period. The family now takes a ritual purification bath and, within some families, the heads of men and older boys are shaved. Nails of family members are now cut. The family cleans the home for the first time since the death. On the 11th or 12th day the family hosts a meal on behalf of the deceased. The preferred date and details of these closing rituals of mourning differ from region to region. Even within a given region, there are variations, due in part to migration with many families continuing to practice the specific rituals of their place of origin. Pinda daan is given to the deceased and at least two other generations of the ancestors in order to ritually unite the Atman with the ancestors in the next world. Pinda daan is followed by a ritual meal called *Brahmin bhoj* (feeding Brahmins). The traditional number of Brahmin priests should be 12, but in actual practice the number varies depending on the economic conditions of the family, local customs, and the availability of Brahmin priests. The Brahmins are also given cash and clothes. In earlier times, and to some extent even in rural areas today, some wealthy, higher caste families give their purohit a female cow, which he in turn is understood to make available to the deceased. This act is known as *go-daana* (gift of a cow). The prêt is to hold onto the tail of the cow and thereby be transported across the Vaitarani River, a parallel to the River Styx, and across the *Kshira Sagara* (cosmic ocean of milk). On reaching the other side, the Atman is in position to begin again the cycle of rebirths.

On the 13th day the dahak represents the family and accepts alms from many guests who attend a special meal to mark the end of the mourning period and to welcome the family back into society. Another male member of the family records the names of the givers and amounts in a notebook, which is consulted in the future in order to provide compensatory support when there is a death in others' families. This practice bolsters bonds with friends and acquaintances outside the extended family and constitutes an efficient folk insurance system, one lacking any middleman or hidden costs. The death rituals are now at an end, but acknowledgment of the death may continue in several ways.

On the 31st or sometimes 40th day, pinda daan is performed with some portions given to three kinds of animals—crow, cow, and fish. This is an abbreviated form of the rituals of the 11th day and is done to unite the recently departed with the ancestors and to further mark the end of the ritual impurity. These rituals may also be performed on

the 11th day and not repeated on the 31st. However, some families perform pinda daan each month for one year. For example, in West Bengal, *masika* (monthly) *shraddha,* centered on pinda daan, is performed for one year. Alternatively, families preferring a streamlined agenda perform much the same rituals but called *samvatsarika shraddha* after 6 and 12 months. After 12 years, preferably either during *shraddha paksh* or the fortnight corresponding to the 12th anniversary of the family member's death, the bereaved visit Gaya in Bihar, a famous pilgrimage center associated with honoring the ancestors, to perform pinda daan.

In North India, in earlier times, a brief ceremony known as *barsi* involving ritual feeding of the ancestors was performed on or close to the first and second anniversary of a death. The combination of the shraddha rituals at the time of death plus the two rounds of barsi served to help the individual achieve peace in successive levels of the cosmos—earth, sky, and heaven. Nowadays, it is common for the barsi rituals to be folded into and performed at or near the conclusion of the shraddha rituals.

For one year, the family and especially the dahak are to avoid participating actively in celebrations: No weddings, housewarmings, and so forth are to be performed. However, it is now common for friends of the mourning family to coax them into joining them to participate in *Holi* and other festivals if only in minor ways. In this way, the dead remain honored and the living help each other to move on.

Shraddha Paksh (Ancestors Fortnight)

Annually during *Ashwin krishna paksh* (the dark fortnight of *Ashwin,* corresponding to September-October), the ancestors are remembered and honored. Pinda daan in the home with Brahmins in attendance is performed. Afterward, foods known to have been preferred by various ancestors are served to the Brahmin purohit, who also receives gifts of clothes, fruit, and cash. If there has been a death in the past year, the purohit will come on the day of shraddha paksh corresponding to that of the death of the recently departed. If more than one family member has been lost in recent times, the family may hold rituals on each of those days. In any event, it is customary for all families to participate in shraddha paksh on the last day, *amawasya* (new moon day), of the fortnight to show respect for all of their ancestors, including young children who may have died and ancestors whose date of death is no longer known.

In keeping with the long process of death rituals previously outlined, during which time the prêt remains unsettled, that is, it remains an active, albeit unseen, participant in this world. This belief has given rise to widespread belief in attacks by spirits of the dead and, in turn, to a range of exorcists of whom the *Aghoris,* a sect headquartered in Banaras, are deemed to be the supreme practitioners. In eastern Uttar Pradesh and western Bihar, there is widespread belief in *Brahms,* spirits of Brahmins who died either by accident or murder. At first those spirits are considered to be potentially angry. Initially, they may be propitiated, but in time worshipped if individuals honoring a Brahm come to attribute any good fortune to him or her. As worship replaces propitiation, a Brahm may evolve into a godling with widespread following and even an associated day of week for devotees to visit the site associated with him or her.

If and when a soul achieves complete peace so as to experience *moksha* (release from the cycle of rebirths), the individual Atman joins and becomes part of the universal Atman. This outcome may occur for truly exceptional, saintly individuals, but it is more of an ideal to aspire to rather than a goal that common people look to achieve.

The Doms

Dom carries two meanings: the caste of funeral pyre tenders and the occupation of funeral pyre tending. Throughout northern India, Doms occupy the lowest or among the lowest rungs of the caste hierarchy, the challenge for that rank coming only from *Bhangis* or sweepers, particularly those who clean toilets. One Dom in Ballia District of eastern Uttar Pradesh, in imagery recalling Atlas holding up the world, has proudly stated, "We are the lowest of the low." He went on to explain that all other castes benefit by having the Doms as a baseline against which to assess their position in the caste hierarchy. He suggested that beyond being indispensable in death rituals, Doms are implicitly present throughout the entire lifespan due to the part they play in defining the social structure. Historically, Doms have occupied such a low position because

their job is both polluting (the corpse) and dangerous (the risk of courting the wrath of the prêt should the rituals not be performed correctly).

It is interesting that entry into this life is also overseen by a low caste functionary, the *Chamain* (meaning woman of the leatherworkers' caste and midwife), whose duties are also seen to be both polluting (blood) and dangerous (risk of death of the mother or baby). Of these two critically important low caste functionaries, only the Dom is reviled. One cannot be sure that he has successfully performed his duties at every cremation he has overseen. By contrast, the midwife's success is evident in the survival of the children she has delivered. Moreover, although for decades nearly all deliveries have been in hospitals, even in fairly recent times, low caste midwives have commonly served as wet nurses for the infants of higher caste women and have been affectionately dubbed *Chachi* (Auntie) by the older children they have delivered. Such intimacy with Doms is unthinkable. It is worth noting that the sequence of cool-hot-cool of the death rituals (giving Ganga, cremation, placing the ashes in water) is paralleled by the low-high-low status of the functionaries overseeing the three major events in life—low caste midwife for birth, high caste Brahmin purohit for wedding, and low caste Dom for cremation.

Banaras, or Varanasi, has the most sacred Hindu cremation grounds in all of India. The Dom Raja (King of the Doms) lives in an immense home beside one of the burning ghats. As the ranking member of a hierarchy of funeral pyre tenders, the Dom Raja is quite wealthy. Immediately below him are the foremen who oversee the third tier, the workers who serve at the cremation fires. Access to any of these positions is a birthright resting on membership in particular families of the Dom caste. Men of families employed at the cremation grounds in Banaras have clearly defined entitlement to particular fire sites and particular days of week.

In Banaras, hierarchy of Doms is mirrored in a three-tier prestige hierarchy of sites. One or two funeral pyre sites are reserved for high-ranking individuals whose families are able and willing to pay much higher fees to the Doms. The vast majority of cremations take place at the ordinary sites at the two cremation grounds in Banaras. An electric crematorium is a third option and is now used throughout urban India.

Elsewhere in northern India, especially in villages and small towns, Doms also have an inherited privilege to serve in that capacity at particular places but without the elaborate hierarchy found in Banaras. In keeping with the custom of individuals of low ranking castes enjoying temporary elevation into honorific positions, throughout much of northern India, Doms lead processions while playing a curved copper horn known as a *singha* for Kali Puja and on other festive occasions. The Doms of Banaras do not play the singha and are not even aware of its association with their caste. Its absence from Banaras and collective memory is due to the high volume of cremations and the sacredness of those cremation grounds. Thus, the Doms of Banaras have neither the time for peripheral ceremonial duties nor, despite their low rank in the broader social structure, the need to seek higher status. The most sacred of India's cremation grounds can be said to confer on them the rank of "highest of the lowest of the low."

HIV/AIDS

HIV/AIDS is an acronym that stands for human immunodeficiency virus/acquired immune deficiency syndrome. HIV is a retrovirus and AIDS is the disease a human experiences when the HIV virus reaches an advanced stage. There are two species of HIV that infect humans: HIV-1 and HIV-2. HIV-1 is more easily transmitted than HIV-2 and is the cause of the majority of HIV infections worldwide.

The HIV virus weakens the immune system of its host to a point in which individuals may acquire certain infections, such as tuberculosis, cryptococcal meningitis, and severe pneumonias, which are termed opportunistic infections. These opportunistic infections are life threatening and cause death in the majority of AIDS patients who don't have access to treatment. For many years in many parts of the world and for millions of people still today, acquiring HIV/AIDS translates into death a few years later.

The first AIDS cases were identified in the United States in 1981, followed by those in Uganda the next year. Early on, the condition was also nicknamed "slim disease" because advanced HIV infection causes severe bodily wasting. The early stages of the epidemic were characterized by baseless finger pointing in an attempt to identify particular individuals, communities, cultures, and lifestyles as responsible for the spread of HIV. Haitians, homosexuals, and Africans received the largest burden of unfounded blame.

The current estimates are that 33.2 million people are living with HIV/AIDS. It is believed that the number of new infections peaked in the late 1990s, yet in 2007, there were still 6,800 new HIV infections each day, totaling 2.5 million new infections during the past year. HIV/AIDS is among the leading causes of death worldwide and the number one cause of death in sub-Saharan Africa, a region that has disproportionately borne the burden of the epidemic. Cases have been reported in all regions of the world, but more than 95% of those living with HIV/AIDS are in low- and middle-income countries. Beyond Africa, the second-most-affected region is the Caribbean, followed by growing concern in parts of Eastern Europe and Asia.

Social Causation of Disease

HIV/AIDS can be transmitted through any of the following modes: sexual transmission (e.g., unprotected oral, anal, or genital contact with another person's infected sexual secretions), shared injection drug use paraphernalia, mother to child transmission, and blood-to-blood contact. These modes of HIV transmission are well known and lead to the conclusion that HIV/AIDS is entirely biologically preventable. Yet both epidemiological and sociological accounts have drawn attention to the social factors that make transmission of the disease more likely in particular communities given their social location. Clearly there are important social, economic, and political factors to take into account when understanding this condition, its prevalence, as well as its transmission and treatment. Poor and marginalized people are more likely to contract and die from the disease than those with access to material resources. Gender discrimination, poverty, and political repression are all examples of social factors that can disadvantage certain populations and create increased vulnerability to the disease.

Relationship to Gender

Gender is an important social causation to be taken into account when considering HIV/AIDS. Globally, women are 50% of all adults living with HIV/AIDS, and in sub-Saharan Africa they make up 61% of all people living with HIV/AIDS. There are several reasons for this. One is that women are biologically more susceptible to HIV infection than men due to their anatomy. Yet an even greater gender factor is gender inequalities in social and economic status. These inequalities may increase the likelihood that women will contract the virus because they may lack the power to refuse sex. Additionally, sexual violence against women, such as rape or other forms of sexual abuse, may also increase their vulnerability to acquiring HIV/AIDS, especially in areas where the epidemic already has a high prevalence in the general population.

Relationship to Poverty

Poverty is another factor that plays into the transmission of HIV/AIDS in several ways. First, when

individuals and families are economically poor, they often have less resources and opportunities that can be drawn upon for household income. In such contexts, poor people may partake in certain behaviors to secure income, such as transactional sex, which exposes them to greater risk of HIV/AIDS transmission. Second, the poor also often lack access to safe water, nutritious food, and quality health care—three components that are critical for ensuring that their bodies can defend themselves from deadly opportunistic infections.

Relationship to Political Repression

Political repression as a social causation of disease refers to policies and regimes that oppress particular populations and make them more vulnerable to infection. This concept can also be called structural violence. Policies of forced displacement by either governments or international agencies are one example of the ways in which the policies and conduct of institutions can limit the livelihoods of and access to social services for particular populations. Another political factor that is related to the social causation of HIV/AIDS is international drug patent and pricing. These international policies often prioritize profit of drug developers and manufacturers over guaranteeing that those who are sick and need the medication have access to the lifesaving medications. This translates into inadequate care and treatment options for particular populations, which can lead to more HIV/AIDS infections.

Behavioral Analysis

Another factor that is important to take into account for understanding the causation of HIV/AIDS is particular behaviors that individuals undertake, which significantly increase their risk of infection. Such risky behaviors include taking drugs with unclean needles or practicing unprotected sex. Many AIDS prevention programs attempt to address this through behavior change efforts. Such programs place emphasis on educating individuals and groups about the negative effects of particular conduct, and then encouraging people to change their behaviors by participating in needle exchange programs, being monogamous in their sexual relations, and using condoms and dental dams.

Responses to the Epidemic

Responses to HIV/AIDS have broadly fallen into three categories: prevention, treatment, and care. Prevention generally includes education about the disease as well as how one can prevent transmission of HIV/AIDS from one person to another. As previously noted, these various forms of prevention are often termed behavior change efforts. One popular model is the "ABC Model," where A stands for *abstinence,* B is for *be faithful to one's partner,* and C signifies *condom use*. Harm reduction programs operate on the theory that people will sometimes participate in risky activities, yet these people ought not be punished for this; rather, they should be given the tools to prevent infection. One example of a harm reduction program is one that offers needle exchange options. Examples of other prevention programs include medical services for pregnant women and newborns and centers for testing and counseling. Others work to prevent HIV/AIDS through more advocacy-based approaches, which strive for structural change to address underlying social causations and inequalities, such as drug pricing or poverty. And finally, some have demonstrated that ensuring treatment for those with HIV/AIDS is a form of prevention in itself. When people know that medication is available for treatment, it encourages people to get tested and know their HIV status, which, in turn, leads to preventing the transmission of the virus. Additionally, HIV that is well controlled with treatment is less likely to be passed along to another individual.

Treatment for HIV/AIDS is accomplished through medications called antiretrovirals (ARVs). ARVs do not cure a person of HIV or AIDS, but they can help people with HIV live nearly normal lives by reducing the amount of HIV virus in the blood. This helps an individual's immune system work properly and fight off other infections. Individuals only take ARVs when they develop a serious HIV-related illness (opportunistic infections) or when their CD4 (cells that control one's immune system) count drops significantly. For the majority of people, this happens approximately 8 to 10 years after infection. The first ARV was called azidothymidine (AZT), which was a cancer medication that was found effective against HIV. It was introduced as a way to treat HIV/AIDS in

1987. In 1996, highly active antiretroviral therapy (HAART), which entails combining different classes of HIV drugs for a more potent effect, was introduced. It is also called the "triple drug cocktail" because generally it combined three forms of medication into one treatment therapy. After HAART became available, AIDS death rates dropped drastically in the United States and other countries where people could afford the drugs.

Beyond ARV treatment, treatment also exists for opportunistic infections. This includes treatment for sexually transmitted infections, tuberculosis, specialized forms of pneumonia, brain infections, and herpes. These forms of treatment are often used alongside ARVs and were available long before ARVs.

Care responses for HIV/AIDS include ensuring that food security and proper nutrition are available for people living with the virus and disease, as well as psychosocial support and care for HIV/AIDS patients and their families. Furthermore, availing ongoing prevention services to ensure that those already with HIV/AIDS do not transmit the virus is a component of care that is also important.

Global and Local Responses

Within the framework of prevention, treatment, and care, there have been global and local responses to HIV/AIDS. Globally, the United Nations has stressed HIV/AIDS as a global challenge deserving serious attention. The Joint United Nations Programme on HIV/AIDS (UNAIDS) was established in 1994, and the Security Council passed resolution 1308 in 2000, acknowledging HIV/AIDS as a global security threat. One of the major multilateral initiatives has been the Global Fund to fight AIDS, tuberculosis, and malaria. The Global Fund was established in 2002 as a public-private approach to prevention, treatment, and care in 93 countries. In 2004, the United States began an AIDS program called the President's Emergency Plan for AIDS Relief (PEPFAR), which translated into $15 billion toward the global AIDS pandemic.

On the local level, communities have come together to educate one another to prevent infection, offer counseling and psychosocial support to those with the condition, provide primary health care for opportunistic infections, care for orphans left behind by deceased family members, advocate for access to medications, and ensure that nutritional needs are met. One innovative response has been the formation of groups and networks of people living with HIV/AIDS. These groups provide unique opportunities for people already living with the virus or directly affected by it to play a proactive role in curbing the epidemic. Several of these community-based groups sprouted in Africa in the 1980s and 1990s.

One of the most well known community-based responses to HIV/AIDS is The AIDS Support Organisation (TASO), which was founded in 1987 in Uganda. Unified by common experiences of stigma and discrimination, the founders, people who had been impacted by HIV/AIDS in various ways, began informally meeting in each other's homes to offer social support and encouragement. These types of efforts have contributed significantly to eliminating stigma and discrimination of those who have HIV/AIDS. This was vital because earlier in the epidemic many myths were circulated about HIV/AIDS and its transmission. Many people were afraid to have any physical contact with individuals who had HIV/AIDS, and many who had the disease lost their jobs. Over time as the truth about transmission has become more prevalent, stigma and discrimination has reduced.

Another group that is largely composed of individuals who are living with HIV/AIDS is the Treatment Action Campaign (TAC) in South Africa, which has unfolded into a network of over 10,000 people who have had success in putting HIV/AIDS on the public agenda in South Africa and beyond. They are especially known for their role in pressuring drug companies to drop their case against the South African government on issues related to generic drugs and for rolling out the South African government's HIV treatment program. Similarly, ACT UP in the United States has also contributed significantly to reducing stigma and carrying out political advocacy campaigns to fight HIV/AIDS.

As demonstrated by the array of responses, HIV/AIDS directly affects those affected by the disease as well as family and community members who are around those with the disease. In communities where HIV/AIDS prevalence is high, many sectors of society can be heavily impacted. As working-age populations become sick and are unable to work, production and consumption are affected, thereby

disrupting economies. Education sectors also suffer as teachers become ill and are no longer able to teach. Many pupils who have HIV/AIDS themselves or whose family members are sick are also prevented from attending school due to not feeling well themselves, needing to take on additional chores at home, or for being unable to pay school fees. Obviously, the health sectors are also affected in communities with high prevalence of HIV/AIDS. The public health and primary care infrastructure becomes overwhelmed. Additionally, many countries lose large numbers of health workers to the disease itself, as well as the fact that many workers don't want to work in contexts where vast amounts of the population are dying.

AIDS and Death

In communities with high prevalence rates of HIV/AIDS, death becomes a more apparent part of society. HIV/AIDS affects national mortality rates, life expectancy, and population growth. In some countries in southern Africa, where prevalence is between 15 and 30% of the adult population, communities strive to cope with mass amounts of illness and death. Funerals and burials become regular social occasions. Furthermore, in such communities the mental health of survivors can be greatly affected. A recent study in rural Uganda conducted in 2000 through 2001 revealed a depression rate of 21% in two districts where HIV/AIDS prevalence was extremely high. This level of depression obviously affects all sectors of society and the capacity of members of the community to plan for the future. Beyond mental health concerns, HIV/AIDS also lowers the life expectancy significantly. In some sub-Saharan African countries, life expectancy has decreased to 40 years due to HIV/AIDS.

Looking Ahead

Every two years, thousands of clinicians, academics, community health and social service providers, aid agencies, students, and activists gather at the International AIDS Conference hosted by the International AIDS Society. At these meetings, historical debates are hashed, cutting-edge research is presented, and innovative social programs are showcased. These meetings also highlight some of the themes that are on the horizon in the field of HIV/AIDS, which includes the development of a preventive AIDS vaccine, of which there is extensive research and significant hope invested but no solid results yet. A preventive AIDS vaccine would work by training the body to defend itself against a pathogen by introducing an immune response. Thus, when someone actually acquired the infection, his or her body would be able to fight it. Related efforts are increasingly directed toward microbicides, which are compounds, often gels or creams, that one applies inside the vagina or rectum to protect against HIV. There are several forms that are at various stages of clinical development. Finally, efforts are increasingly being directed at expanded forms of treatment of HIV/AIDS. New drugs are frequently being introduced and tested through clinical trials to overcome drug resistance and reduce side effects, providing hope that more efficacious forms of treatment may arise.

Holidays of the Dead

Holidays of the dead were and are present in many various cultures and religious traditions around the world. They can be both of religious character as well as secular. Contemporary holidays and festivals of the dead have their origins in ancient rituals and beliefs. The two most well known and popular are: Halloween, especially popular in the United States but also found across contemporary Western civilization, and *El Día de los Muertos*, originating in Mexico. Other, lesser known examples are Christian All Saints' and All Souls' Days, *Bon Festival,* which is a Japanese Buddhist custom, and the Vietnamese festivals *Thanh Minh* and *Tet Trung Nguyen.* All of these have their sociological (corporate and psychological) and individual dimensions and functions (e.g., building and sustaining the self-identity, coping with loss, and integration with local community). Each of the previously mentioned holidays will be considered from three main aspects: history and/or ancient roots, beliefs, and rituals.

All Saints' and All Souls' Day

According to Roman Catholic tradition, the 1st of November is All Saints' Day and the 2nd of November is All Souls' Day in the religious ritual calendar. The former is devoted to the commemoration of all Catholic saints, who at first were usually martyrs. The holiday arose from the tradition of solemnizing the martyrs in Christianity and the commemoration of Christ's martyrdom. We find the first traces of this tradition during the days of the early Christian church in Antioch, on the Sunday after Pentecost. At first only martyrs and Saint John the Baptist were honored by a special day, but gradually, other saints were added to the religious calendar. Pope Gregory III (731–741 C.E.) consecrated a chapel in the Roman Basilica of Saint Peter to all the saints and fixed the date for communal commemoration to the 1st of November, when Catholic churches hold special masses. This day is now a national holiday in some countries (e.g., Poland).

All Souls' Day is focused not on those in heaven, as is the case of All Saints' Day, but on those in purgatory, which according to Catholic teaching are the average believers. The belief underlying this holiday is that the prayers of the living, on behalf of the dead, can help the dead achieve salvation and go to heaven. On this day, all the masses are requiem, dedicated to the dead; believers donate to the Church for the sake of salvation of the souls in purgatory. The ritual also involves visiting cemeteries and gathering together and praying beside the graves of family, friends, famous people, and national heroes. People decorate the gravesites with lit candles, flowers (chrysanthemums usually in Central and Eastern Europe), and wreaths. The general character of this holiday is rather sad, full of grief, and pathos. This Catholic tradition goes back to the sixth century Benedictine monks who decided to offer the mass on the day after Pentecost for their deceased community members. In 998 C.E., Odilo, Abbot of Benedictine monastery in Cluny, changed the date of their commemorative mass to the 2nd November, the day after the Feast of all Saints. This custom spread, and in the 13th century, Rome put the feast on the Church calendar.

Before Christian times, in late October/early November in the region of today's Eastern Poland and Lithuania, there was a Slavic pagan tradition of *Vėlinės* or *Dziady*, a week-long holiday of the dead. It was believed that during this time each year, the souls of the dead leave the afterlife world and come back to visit their family and home.

People gathered in cemeteries and visited the graves of family and friends. Bringing milk and beer, they danced and feasted for several days. The holiday was also celebrated at home with a huge supper for the whole family. Afterward the food was left for a night on a table for the deceased, and then given to the poor and homeless a day later. Some aspects of these holidays were incorporated into the later Christian rituals of All Souls' Day introduced in these regions during the 12th century. In this part of world, All Souls' Day is a holiday commemorated by nonbelievers as well as Christians.

Halloween

Celebrated on the 31st of October, the name of this holiday comes from All Hallow Even (the eve of All Saints' Day). Irish immigrants in the 19th century brought this holiday to the United States, and from there it spread throughout the West, although it is still more popular in the United States. This holiday arose from the fusion of the pagan Celtic tradition of *Samhain* (or *Samuin*), the Christian All Saints' and All Souls' Days, and the introduction of the last into Pagan territories. Samhain was a celebration of the end of summertime, probably devoted to Saman, god of the dead.

The belief underlying this holiday is that the Halloween night belongs to the dead, who emerge from their graves and wander the roads, the sea, and every other area. The border between the two worlds, of the living and of the dead, is particularly vague and indefinite on this night, thus the communication and exchange between the two worlds is present. The ritual involves, as an example among a wide range of activities, "tricking or treating," where children disguised as skeletons, ghosts, and so forth go from house to house saying "trick or treat"—looking for sweets and organizing costume parties. Many of the elements and symbols of Halloween are now found around the world, and it is also a rich source of pop culture themes used in movies, music, and literature. The general character of this holiday is joyful, full of happiness, parties, and laughter.

El Día de los Muertos

El Día de los Muertos (The Day of the Dead) is the Mexican name for All Saints' and All Souls' Days, which are celebrated on the 1st and 2nd of November. It is the most important celebration ritual in the Mexican calendar. The underlying belief of this holiday is that the souls of the dead return to the living and reunite with their relatives and friends. Crucial for the feast are the days between October 31st and November 2nd, when offerings, food, and drinks are presented to the dead. El Día de los Muertos in Mexico is a private and family feast rather than a public one. The ritual involves building a special altar for the dead (*la Ofrenda*) in the home. La Ofrenda usually consists of boxes put on a table and covered with white cloth or paper, sacred images of Jesus or Saint Mary, photographs of the deceased and things that remind the family of the deceased in some way, a candle for each spirit, as well as sugar *calaveras* (skulls) and the *pan de muerto* (bread of the dead). When the altar is ready, the dead are called home and welcomed to many hours of companionship with their living relatives and friends. At midnight on October 31st, an elaborate banquet, called *Hanal Pixal* (dinner of the dead), is served for the spirits of the deceased and the living.

El Día de los Muertos is also celebrated in cemeteries. Graves are cleaned and decorated with marigolds (flowers of the dead in Mexico), offerings of copal (resin incense), candles, calaveras, and food. Family members may take turns or all may stay by the grave the whole night to spend it with the spirits of their dead relatives and to share the foods with them. The general character of this holiday is a mixture of sadness and solemnity, caused by the memory of the death of the deceased, with feasting and enjoying their temporary return. The holiday in Mexico arose as a fusion of Christian and pre-Hispanic elements of tradition.

Bon Festival

Bon (*Obon* or *Urabonne*), the Feast of Lanterns, is a Buddhist holiday that takes place in Japan between August 13 and 16 (according to Solar calendar) or July 13 to 16 (according to Lunar calendar). Its underlying belief is that, during this time, the spirits of the dead come back to their former homes to reunite with their families. The Buddhist myth, on which the holiday is based, tells the story of Mokuren, a disciple of Buddha, who used his supernatural power to look upon his dead mother. He saw her great suffering in the Realm of Hungry

Ghosts and asked Buddha for help. He was told to make some offerings to the priests just finishing their summer retreat. Mokuren followed Buddha's instructions and as a result his mother was released.

Before this holiday, people clean their houses and prepare them for a visit of special guests. They also clean the gravesites. The ritual involves special Buddhist services held in temples and houses of ancestors, dead relatives, and friends, particularly for those who died in the last year. Apart from Buddhist services, the celebrating of Bon includes visiting gravesites and a ritual supper in which the spirits of the deceased are believed to take part. The spirits are led from their graves to their family homes with lanterns and then are given food, flowers, and incense. Another part of the Bon celebration is a ritual dance—*Bon Odori*—performed by people in front of temples and in town squares. The dance commemorates the joyful dance of Mokuren. The festival ends with the floating of the lanterns—*Toro Nagashi*. Lanterns symbolize the spirits of the deceased; they are lit and then floated down rivers. This part of the ritual symbolizes returning the spirits to the world of the dead. The ceremony culminates with fireworks.

Over time Bon evolved from a religious holiday into a family holiday, when families reunite and people return to their family homes and commemorate the dead. It is a religious holiday, but it is also a joyful social occasion. Some of its elements (date, music, and dance) vary according to the region, but the major functions and mythical origins stay the same. The Bon holiday is celebrated also in other parts of the world (e.g., Brazil, Malaysia, United States, and Canada) in Japanese communities.

Thanh Minh and Tet Trung Nguyen

Thanh Minh is celebrated on the third lunar month. A few days before the holiday, family members clean the gravesites and paint the tombs. The ritual involves visiting the graves of ancestors to commemorate them and to offer flowers, food, votive papers, and incense to the dead.

The other important holiday of the dead in Vietnam is Tet Trung Nguyen (Wandering Souls Day)—the second largest festival in this culture. It is celebrated on the 15th day of the 7th month, but it can also be held at any other convenient time during the 2nd half of the month. The underlying belief of this holiday is that after death, the soul is judged and afterward sent to heaven or hell as a reward or punishment for his or her life. This holiday is the best time for prayers for the sake of condemned souls. On this day, it is believed the gates of hell are opened and the hungry souls fly out in search for food. Souls that have living families or friends go home and find what they need on their family altars, but those who have no families or who have been forsaken by the living are doomed to wander helplessly. They are the "wandering souls" in need of food and prayer. Public altars full of offerings are built in pagodas and many other places for the use of wandering souls.

The main celebration takes place in open air or in the largest room of the house (so it can hold many wandering souls). During the ceremony, tables are covered with offerings: three kinds of meat, five kinds of fruits, and other foods, such as rice cakes, soup, and meat rolls. The ritual also involves burning money and clothes made of votive papers.

HOLOCAUST

The Holocaust was the systematic extermination of more than 6 million European Jews, perpetrated

by Nazi Germany between 1939 and 1945. The event is also known as the *Shoah* or "annihilation" in Hebrew and as *Churban* or "destruction" in Yiddish. The Holocaust has certain features that distinguish it from other human catastrophes: It resulted from centuries of religious and philosophical hatred of the Jews, and it was implemented as the official policy of a modern state. Perhaps most significantly for how one understands death and the human experience, the Holocaust was an act of mass murder that rested upon a fundamental view of the value of a human being, a view that was in direct conflict with the teachings of Jewish tradition. In the following text, a brief historical background, some historical highlights of the Holocaust, and some ramifications of the Holocaust for understanding death and the human experience are presented.

Historical Background

The hatred of the Jewish people that paved the way to the Auschwitz extermination camp has its roots in the early centuries of Christianity. According to Saint Ambrose (ca. 340–397), it was not a crime to burn synagogues. Saint John Chrysostom (347–407) described the Jews as enemies of God and was among the first to accuse the Jews of deicide. While Saint Augustine (354–430) recognized the Jews as witnesses to the truth of the Hebrew scriptures, he viewed their exile as a divine punishment for rejecting Christianity.

The first large-scale murder of the Jews at the hands of the Christians took place during the First Crusade in 1096, when thousands of Jews were slaughtered in the Rhineland. The widespread slaughter of the Jews continued in England in 1190, in Germany in 1348–1349, in Poland and the Ukraine in 1648–1649, and in the 1880s and 1903–1906 in Russia. Throughout these centuries, Jews were labeled agents of Satan, desecrators of the Host, sorcerers, and vampires. In 1290, they were expelled from England, in 1394 from France, in 1420 from Austria, in 1492 from Spain, in 1496 from Portugal, in 1512 from Provence, and in 1569 from the Papal States. Indeed, Jews were expelled from almost every country in Europe.

With the coming of the Enlightenment in the 18th century, the philosophical anti-Semitism of the intellectuals was added to the theological anti-Semitism of the Christians. Nearly all of the great philosophers of the 18th and 19th centuries—including Voltaire, Immanuel Kant, Johann Gottlieb Fichte, G. W. F. Hegel, Arthur Schopenhauer, and Friedrich Nietzsche—delivered diatribes against the Jews. In addition, the advent of modern scientific method brought with it theories that associated character traits with biological origins, from which arose modern race theory. Thus Nazi ideologue Alfred Rosenberg maintained that humanity was being poisoned not only by Jewish blood but also by Judaism because the –ism is in the blood. The Nazis' annihilation of the Jews was based on an all-encompassing worldview that targeted both the Jews and Judaism for extinction. Because the Nazis' chief instigators were thoroughly versed in modern philosophy, science, and cultural history, they were able to use that expertise to suit their own ends. The Holocaust, then, was not the work of lunatics and hoodlums; rather, it was conceived and carried out by some of the world's most highly educated people.

In keeping with a major line of philosophical development from the Enlightenment onward, the Nazis sought the destruction of the God of Abraham and everything He signifies through the destruction of God's chosen. It is perhaps startling but certainly not surprising, then, to discover that by 1940, nearly half of the intellectuals of Germany—doctors, attorneys, and professors—were members of the Nazi Party.

On November 9, 1919, one year after World War I had ended, the Weimar Republic was born. Disgruntled over Germany's loss of the Great War, many Germans joined anti-Semitic right-wing groups, such as the Thule Society. In January 1919, the Society founded the German Workers' Party. By the time they took the name National Socialist German Workers' Party on February 24, 1920, Adolph Hitler had ascended to the leadership of the Party. On January 30, 1933, after the Nazis had won more seats than any other party in the parliamentary election, he was appointed Chancellor of Germany.

Fueling the Nazis' rise to power were not only centuries of Jew hatred but also years of hardship that befell Germany after World War I. Many Germans blamed the Jews for Germany's humiliation in the Treaty of Versailles. In addition, the first years of the Weimar Republic were marked by

runaway inflation. In January 1921, 64.9 marks were the equivalent of 1 U.S. dollar; in November 1923, 4.2 trillion marks were the equivalent of 1 U.S. dollar. The late 1920s, then, saw an increase in the popularity of the Nazi party, who promised to do something about Germany's humiliation and its economic condition. With the onset of the Great Depression in 1929, a catastrophe that affected the entire world, the Nazi Party appealed to more and more people, until they won more seats than any other party in Germany's parliamentary elections of November 1932.

By the end of March 1933, the concentration camp Dachau was in operation, a camp initially opened to detained enemies of the Nazi Party. In that year, a series of laws were passed to begin the project of legislating the Jews out of German society: Everything done to the Jews in Nazi Europe was legal under the law of the Third Reich. The year 1933 also brought for the Nazis their first diplomatic recognition, with the Vatican Concordat of July 20. On September 15, 1935, the infamous Nuremberg Laws were passed, officially defining a Jew as anyone with a Jewish grandparent (with the Jewish grandparent being defined as anyone who belonged to a synagogue); the laws also defined as a Jew anyone who had converted to Judaism, thus making it clear that the ultimate target was both the Jews and Judaism. By 1939, numerous other camps had been opened, including Buchenwald (1937) and Mauthausen (1938).

The Holocaust

On the night of November 9, 1938, the date that many designate as the beginning of the Holocaust, there occurred the first massive round up of German Jews known as *Kristallnacht,* or the Night of Broken Glass. Thirty thousand Jews were arrested, 267 synagogues were set aflame, and 7,500 shops were looted. Within weeks of the invasion of Poland on September 1, 1939, the Nazis began setting up the first ghettos. Once the ghettos had been established, every Jew in Nazi Europe was homeless, living in a ghetto, in a camp, or in hiding. The ghettos functioned not only as a gathering point for the Jews prior to being sent to the extermination camps but also as an instrument of extermination in themselves. The daily ration of food in the Warsaw Ghetto, for example, was about 220 calories, with 7 to 8 people occupying every room in the ghetto.

The mass killing operation began on June 22, 1941, when Germany invaded the countries of Eastern Europe, from the Baltic to the Black Sea. Four *Einsatzgruppen* (or killing units) followed the army as it advanced. Their assignment was to kill every Jew they could find. On January 20, 1942, Reinhard Heydrich, head of the Reich's *Sicherheitsdienst* (or Security Service), convened the Wannsee Conference on the outskirts of Berlin, where government officials worked out the logistics for the annihilation of European Jewry. On December 8, 1941, the first of six camps designed for the purpose of gassing and burning the Jews went into operation at Chelmno. By the end of March 1942, the Sobibor and Belzec extermination camps were operational, followed by Majdanek in April and Treblinka in June. The most infamous of the murder camps was Auschwitz-Birkenau, where the first transport of Jews marked for death arrived on February 15, 1942. Over the next three years, two-thirds of the Jews of Europe, including a million and a half children, were systematically exterminated.

Ramifications

The Nazis' effort to "purify" the world of the Jews was an effort to rid the world of a certain teaching symbolized by the very presence of the Jewish people. It is a teaching concerning the absolute sanctity of every human being, one that is fundamental to the testimony that the Jews bring to the world. And it is fundamentally at odds with Nazi thinking.

Targeting the Jewish soul and Judaism for complete annihilation, the Nazis set up a special section of the Gestapo, the secret police, called *Judenforschung ohne Juden* (Research into Jewish Matters without Jews). Their job was to learn everything they could about the Jews so that they could most effectively achieve their aim. In their extermination of the Jews, the Nazis set out to destroy the very notion of something holy, of something beyond both personal will and natural accident, that abides at the core of humanity. Assaulting the holy core of humanity, they used the Hebrew holy calendar to plan their attacks against the Jews. By degrees it became illegal to observe the

Sabbath, to study Torah, to pray, to put up a mezuzah, to use a ritual bath, to get married, to have children, to bury the dead, or to wear a beard. In the end, the Nazis reduced the death of a human being into a matter of indifference, and the human experience into a matter of expedience.

The Nazis achieved this end in various ways. They designated children and the elders—those who receive a people's memory and those who transmit it—as first targets. Because the crime of the Jew was existing in the world, the most heinous criminal was the one who brought the Jew into this world: the mother, through whom alone, according to Judaism, blessing comes into the world. Knowing the Jewish teaching that the soul is made of its name, the Nazis undertook an assault on the name. The tearing of the name from the soul took its first concrete form in 1938, when the Nazis added the name *Israel* to every Jewish male and the name *Sarah* to every Jewish female in Germany. In the camps, where a number took the place of the name, Jews were identified by this number in order to receive the meager food ration.

The result of the Nazis' systematic brutalization of the body and degradation of the soul of the Jew was a distinctively Nazi creation: the *Muselmann*. The Muselmann was a creature who should have been dead but was not. He did not speak, he did not eat, and he did not react to blows. Utterly isolated from the living, he fell outside the circle of death and the human experience. He was the denizen of the antiworld that the Nazis had created and to which they had relegated the Jews, empty of life, meaning, and value. He was the embodiment of the Nazi atrocity inflicted upon humanity called the Holocaust. The ultimate goal was to obliterate the very notion of the absolute sanctity of the human being that makes death and the human experience matter.

HOMICIDE

Homicide is literally the death of one person at the hand of another. The term derives from the Latin: *homo* (human being) and *caedere* (to kill). Thus, in its purest sense, the term is free from implication of intent or criminality despite a persistent perception by some to the contrary. These latter views derive from the circumstances under which the life was taken. Manner of death is a shorthand means of classifying "why" a death occurred. There are four traditionally recognized specific categories of manner of death—natural, accident, suicide, and homicide; if a death cannot be conveniently placed into one of the foregoing, the manner of death is certified as "undetermined."

Medicolegal investigators charged with making the determination of manner of death are usually the coroner or medical examiner. The legal system has a vested interest establishing the guilt or innocence of a perpetrator in causing a death. In criminal cases, when the state prosecutor attempts to establish the perpetrator's criminal responsibility he or she must also consider the elements of the crime to properly classify the death: (a) unlawfully causing death, (b) of a living human being, and (c) the perpetrator's state of mind (mens rea). In the completely separate civil legal system, the plaintiff's counsel attempts to show actionable responsibility by the defendant for a death.

An interesting element in the all-important issue of *intent* in medicolegal death certification is that the medical examiner/coroner is not charged with determining the legal construct of intent, rather the inference of intent is made by the prosecutor and then presented to the grand jury; the ultimate determination is by the trial jury. Thus, a hunting "accident" in which an individual is inadvertently killed when mistaken for prey would be properly medicolegally classified as a homicide rather than an accident because the risk and potential outcome of the act were obvious. On occasion, some certifiers tend to follow malleable rules in such cases—perhaps out of misplaced concern over the stigma associated with the term homicide. Regardless, the shooter's intent is not the concern of said certifier.

Culpability of Action

In both legal and medicolegal definitions of homicide, the death may be caused by an act *or omission*. The end result is of import, not the means by which it is achieved. Thus, starving an infant to death (omission) is equivalent to shooting a victim in the head (act) as a homicide, in that, in both instances, the death was achieved as the result of the perpetrator's actions. Also, it is not necessary for the perpetrator to physically contact (either directly as in a beating or by extension as in a shooting) the victim. If a victim has severe natural disease, such as coronary artery disease, and a robber threatens the victim (brandishing a weapon and/or making threats), causing stress in the victim culminating in a fatal heart attack, the perpetrator is directly responsible for the death, which would correctly be designated as a homicide. The broad legal categorization of "homicide" does not require knowledge; however, criminality relates to motive/intent or disregard for others' safety as evidenced by the mens rea. In criminal cases, the perpetrator's state of mind speaks to intent; culpable mental states include intentional/purposeful, knowing, reckless, and negligent. The killer's *thoughts* (as established in court) become the fundamental basis for the legal categorization of the death. Equally important is the perpetrator's understanding of right and wrong and/or the actor's inability to adhere to the right at the time the act occurred, also known as "the insanity defense." The medical specialty of forensic psychiatry/psychology (also known as behavioral science) is devoted to ascertaining a subject's true state of understanding and intent. That there may not be agreement among the various experts speaks to the difficulty in getting to the fundamental truths in some cases. If significant interpretations of the same facts in different ways by specialists can and does occur, it should come as no surprise that lay juries can become hopelessly deadlocked in an individual case.

Systems of Social and Criminal Justice

Another important fact is the tiered justice system in operation—criminal and civil. Although not commonly considered important in homicide cases, the civil justice system may serve to right perceived wrongs in the criminal system. This is in no small part due to the different levels of certainty involved. Typically, criminal courts require scientific evidence "to a reasonable degree of certainty," while in civil litigation, the standard is "to a reasonable degree of probability." The civil standard is best understood as "more likely than not," while criminal courts use a much higher standard of proof. The net result is that a criminal jury may determine that "reasonable doubt" exists regarding the homicide of a victim, while a civil jury, examining essentially the same facts, but using the lower standard of proof, may determine that the perpetrator is responsible for the death of the victim. There is no double jeopardy in such situations because the criminal matter relates to the legal system, while the civil pertains to reparations for the wrong.

Types of Homicide

Jurisdictions vary in the number of legal categories devoted to the act of criminal homicide. These may include capital murder, murder (first or second degree), manslaughter (voluntary or involuntary), and negligent homicide. When the term "homicide" is used in legal categorization, it carries a requisite modifier—an often forgotten element when laity considers the act of "homicide" as inherently bad. Some cite the Old Testament biblical reference of the Ten Commandments dictum, "Thou shalt not kill." In fact, the original text states, "Thou shalt not murder." This extremely important concept may help explain why some view all killing of another person as bad. Equally

important, some jurors may bring such a philosophy to their deliberations—an obvious sticking point in considering potential capital punishment.

Murder is unlawful killing with the intent to kill and/or do serious bodily harm—that is, premeditated malice exists, either expressed or implied. Premeditation is another element, however, that can be formed essentially instantaneously, providing the assailant has formed intent and fully considered the killing. Capital murder occurs under certain limited sets of predefined circumstances, in which the nature of the crime is considered so abhorrent in the jurisdiction that the potential punishment includes state-sanctioned homicide of the perpetrator. Such cases often include the killing of an officer of the law and child abuse murder. In jurisdictions without capital punishment, such cases are treated as conventional murder cases.

Lesser levels of unlawful killing lose the "capital" designation. In murder cases, the qualifiers first or second degree are added, selecting out certain homicides as "worse" than others. In reality, despite the elements of the killing being the same, the major difference is in the potential sentence for the crime. The state, in the person of the prosecutor, considers the facts of the case and determines the appropriate criminal charge based on their understanding of the particulars.

The next lesser level of homicide is manslaughter—unlawful killing without premeditation or malice aforethought. Manslaughter may be voluntary, indicating that the assailant chose to perform the act but did so without forming the intent to kill or do serious bodily harm; examples include crimes in the heat of passion or unplanned homicide committed during commission of another crime, such as shooting an individual during the commission of a robbery. Involuntary manslaughter refers to deaths caused during commission of an unlawful act, such as a drunk driver causing the death of another in a motor vehicle collision. Deaths occurring during a medical procedure, such as surgery, do occur and are generally attributed to the condition precipitating the need for the procedure. For example, death during a cardiac catheterization for coronary artery disease is typically attributed to the latter and assigned a natural manner. Although rarely seen, cases of gross negligence and/or wanton disregard by a medical practitioner may be classed as manslaughter.

The least of the criminal homicides is criminally negligent homicide. In such deaths, the perpetrator demonstrates a disregard for a known and unjustifiable risk that the criminal action could result in serious injury or death, and this disregard must be such that a reasonable person in the same circumstances would not have disregarded the risk. There is no intent in these deaths. Examples would include causing death due to improper operation of a motor vehicle and (depending on case particulars) causing death due to medical neglect (as by bedsores resulting in infection) of an individual under one's care.

Ultimately, in criminal proceedings, the question is an assailant's culpability for the death. Two scenarios occur with some frequency where defense might argue that there is no intent and thus no legal responsibility by the charged. Both tend to be interrelated—multiple assailants and multiple wounds (also known as "overkill"). In the law, the hand of one is the hand of all; therefore, even if a suspect were to engage in what was believed to be a simple robbery but the victim ends up shot and dead, the nonshooting partner in crime is as responsible for the homicide as the one who actually pulled the trigger. The precise legal level of homicide charged may vary, depending on the facts of the case. Similarly, if one of a group of assailants were to merely cut the victim's arm while another stabbed the victim in the heart, both are fundamentally responsible for the death. In a medical sense, both the wounds are physiologically part of the mechanism of death, despite one being arguably less severe *in and of itself*, primarily because the wounds were not inflicted individually but in toto.

Depending upon the circumstances, the act of homicide may be considered justified (as in self-defense), necessary (as in execution by the state in capital punishment), or heroic (as in an act of war). The killing of a lawful combatant during wartime is a part of the process; however, the killing of noncombatants is considered a war crime. The overall determination of "right" and "wrong" in each of these instances serves as the basis for the legal categorization. Although religion does not directly enter into the legal determinations of what constitutes the act of homicide, it is interesting to consider that the three major monotheistic Abrahamic religions—Judaism, Christianity, and Islam—are all heavily influenced by the act of homicide, from the Judeo-Christian Old Testament

story of Cain and Abel to the accounts of Abraham and Isaac/Ishmael.

Certain religious proscriptions against suicide directly relate the stigma of homicide as suicide is the killing of oneself (self-homicide). Interestingly, the era of political correctness has skewed media accounts of terrorist acts by ignoring the suicide stigma with the vast majority focusing on the killer and terming such acts a "suicide bombing," rather than recognizing the usually far more numerous victims in a "homicide bombing."

Special Types of Homicide

A reflection of the fascination humans have with the taking of another's life is evident by the numerous special designations for various categories of homicide, for example, those relating to how the victim is connected to their killer including parricide (patricide or matricide)—killing one's parent (father or mother), fratricide/sororicide—killing one's sibling (brother or sister), and filicide—killing one's child. Additional types of homicide are specific for the type of victim, including infanticide/neonaticide—killing an infant/neonate, regicide—killing of the monarch, and genocide—extermination of an entire class. An increasingly common "special" class of homicide is the killing of a child by the caregiver, either a sitter or a parent. In such cases, defense often attempts to obfuscate the true elements of a case by arguing that an abused victim actually died from nonexistent natural disease or minor trauma, or in the case of homicidal suffocation, that the victim merely succumbed to a natural entity, such as SIDS (sudden infant death syndrome) or equivalent. A similar case can occur in elders and other debilitated/weak victims. "Gentle" homicides, such as asphyxial deaths, may leave precious little physical stigmata with which the medical examiner can work. The recognition of the criminal killing in all cases, especially these types of cases, relies on the investigation of the case, for without suspicion and documentation, it may prove easy for a perpetrator to kill a child and possibly even get away with it.

Mens Rea, or the Intentionality of Action

Society seeks to understand "why" a killing occurred. As such, it is not surprising that the legal basis for classification of killing relies to a large part on the killer's *intent*. In determining what, if any, criminality is associated with the taking of another's life, one must consider motive. The motive influences the demographics of any individual homicide. The perpetrator–victim relationship is important and can affect a jury's determination of responsibility. Even with many seemingly disparate sets of facts, most cases can be narrowed down to one of several basic motives (the classic seven deadly sins). Through the years, the precise meaning of the various terms has evolved, although the general concepts have remained intact. The seven deadly sins as described by Dante in *The Divine Comedy* include *luxuria* (extravagance or lust), *gula* (gluttony or self-indulgence), *avaritia* (greed), *acedia* (sloth), *ira* (wrath or anger), *invidia* (envy), and *superbia* (pride).

The relationship of the offender and the victim is one of the most important factors in understanding a killing and often ties directly to motive. One of the most common homicides involves one spouse causing the other's death. The reason commonly revolves around anger ("they had it coming"), lust ("sex," either too much, not enough, or with someone else), and/or greed (money or the like). Another increasingly common type of homicide is drug-related and/or gang-related killing, which occurs commonly for business purposes—either monetary/territorial greed or pride/revenge.

Life has become devalued, particularly by those seeking escape from poor socioeconomic conditions. An aggravating factor is that death has become glorified in popular culture via media, music, and movies—a "live fast, die young" mentality has bred a new type of perpetrator. Assailants are younger, as they are exposed to violent influences at ever-earlier ages. Additionally, societal dynamics have favored an increasingly mobile populace leading to weaker ties within and between communities with resultant lack of concerned citizen witnesses. As a direct result of myriad factors there has been an increase in stranger-on-stranger crime. Over the past several decades, the solve rate for homicides has decreased with concomitant lack of investigative leads based on victim–perpetrator interpersonal dynamics. Regardless, unprovoked stranger-on-stranger crime is arguably much more difficult to defend than one drug dealer killing another over a deal gone bad.

In certain cases, responsibility for the act of homicide is treated differently, either limiting the assailant's responsibility or expanding it to include other's actions and natural disease. In conventional medicolegal thought, the concept of time since the injury is irrelevant; the medical examiner/coroner considers only the relation of the eventual death to its initiating event (proximate cause). In such situations, a death that can be directly linked back to a prior assault by another individual at some point in time is attributed to the initiating event. For example, a gunshot wound severing the spinal cord, resulting in paralysis, would be considered the cause of pneumonia developing 5 years later from which the victim eventually died. The simple rule of thumb in such instances is the "but for" test—*but for* the original assault, would the victim have died at that specific point in time? In some legal circumstances, the "year and a day" rule applies. This is a legal holdover from English common law limiting legal responsibility for the causation of a death to 366 days after the initial (proximate) act. In such instances, despite causing the original injury—even if it clearly and directly eventuates in a later death— homicide is arbitrarily legally removed as the cause of death if the victim is (un)fortunate enough to live a year and a day past the assault. A related concept has to do with transferred intent. Should a victim survive an attack and make it to medical treatment, the attacker assumes the risks associated with the outcome of medical procedures. Medicine does not guarantee outcomes—even with the best treatment, an individual patient may not fare well for any of a number of reasons, some of which may be foreseen and others not. For example, a patient sustains a wound injuring the torso, requiring a medical imaging study with a contrast agent; the patient is exposed to a chemical to which they are allergic (despite no one knowing that the victim was allergic); and death results from an anaphylactic reaction to the contrast agent. In this scenario, despite the assailant not giving any medical care and despite no knowledge by any of the players that the victim was allergic to the agent, the attacker is ultimately responsible for the death because *but for* the original injury, there would not have been need for the procedure ending in death. In some cases, defense may argue that "the doctors killed the victim" and, at most, all the defendant did was injure the victim. If a victim requires medical treatment, the assailant vicariously assumes the outcome of it. Thus, the homicide may occur from an otherwise natural disease that the victim would not have had but for the original assault.

Finally, a recent trend also directly related to public interest has been the popularization of seemingly all things forensic. Television and movies have popularized the work conducted by forensic science practitioners, which has proved to be enduring entertainment. This two-edged sword of Damocles hangs over homicide investigators. On one hand, the popularization of forensics has meant that juries now better understand complicated principles, such as DNA technology and fingerprint identification. On the other hand, jurors have come to *expect* scientific evidence in all cases, even those where none exists. This latter, so-called *CSI effect* has proved challenging in presenting cases because homicide detectives, despite the scientific impossibility of proving a negative, have been challenged with the unenviable task of explaining why something does not exist.

Honor Killings

Honor killings involve the murder of female family members, usually by brothers or fathers, in retaliation for allegations of premarital or

extramarital sex, for refusing an arranged marriage, or for attempting to obtain a divorce. Honor killings reflect crimes and violence against thousands of women every year all over the globe.

The practice is most frequently found in traditional, male-dominated societies primarily in communities in the Mediterranean Basin, the Middle East, the Indian subcontinent, and sub-Saharan Africa. Such killings take place when male family members feel their power or status in the family has been threatened and are condoned by the following reasoning. First, any sexual relationship of women outside of marriage is considered a shame and sullying of the woman's honor. Second, that honor is the property of the primary male family member and not of the woman herself. Third, women in the family bear immediate and full responsibility for preserving family honor, even against their will and, therefore, deserve the maximum physical penalty when family honor is not maintained.

The murder of females in the Middle East is an ancient tradition. Prior to the arrival of Islam in 622 C.E, Arabs occasionally buried infant daughters to avoid the possibility that they would later bring shame to the family. This practice continued through the centuries. It may still occur today among Bedouins, who consider girls most likely to sully the family honor. Currently, several thousand women a year are victims of honor killings carried out for a wide range of offenses: marital infidelity, refusing an arranged marriage, asking for a divorce, having premarital sex, flirting, wanting to go to college, or even having been raped. Unusual cases include the husband who murdered his wife based on a dream that she betrayed him; the Turkish father who slit his daughter's throat in the town square because a love ballad had been dedicated to her over the radio; or the 16-year-old mentally retarded girl who was raped in Pakistan and found guilty of dishonoring the tribe. Numerous murders are ruled an accident, suicide, or family dispute, if they are reported at all. Police and government officials are often bribed to ignore crimes and to hinder investigations. A woman beaten, burned, strangled, shot, or stabbed to death is often ruled a suicide, even when there are multiple wounds. Many women are buried in unmarked graves, as their existence is supposed to be removed from the community, even after death.

Patriarchy and Honor Codes

The problem of honor killings is not a problem of morality or of ensuring that women maintain their own personal virtue; rather, it is a problem of domination, power, and hatred of women who, in these instances, are viewed as nothing more than servants to the family, both physically and symbolically. Patriarchal systems privilege a male point of view. In such societies, actions that challenge men's sense of control and status will be punished. Honor killings are based on the assumption that women themselves are powerful and dangerous beings. All sexual institutions, such as polygamy, repudiation, and sexual segregation, can be viewed as strategies for containing such female power.

Honor killing is also frequently viewed as self-contradictory, because is it often justified, by its participants and supporters, as an attempt to uphold the morals of a religion, which at the same time generally forbids killing as morally wrong. Ironically, religious moral codes, such as those found in Islam, denounce such elevation of gender status by either men or women, rather emphasizing the equality of the two genders. Indeed, the Qur'an makes clear in chapters four and seven that men and women are not only equal in the eyes of God, but were created together and simultaneously from a single cell.

Collective Acceptance and Social Pressure

Women can support the honor killing of a family member, as most of them agree that the family is the property and asset of men and boys. Women often accept their fate and expect to be executed, even in the case of incest and rape. Such power of culture has conditioned both the victim and the killer to accept their roles. Confessions of honor killers repeatedly testify that their immediate social circle, family, clan, village, or others, expected them and encouraged them to commit the murder—from society's perspective refraining from killing the woman debases her relatives and shames the code of honor set by the community's standards, where the man is the guardian of his female relatives, and consequently, he is supposed to take any measures to satisfy community concerns.

For example, there was a case where an Egyptian father strangled his unmarried pregnant daughter

to death because he believed that other villagers judged him for his daughter's unmarried status. This father killed his daughter to end the shame and stigma he experienced from neighbors. In another incident, a 25-year-old Palestinian man who hanged his sister with a rope maintained that, "I did not kill her, but rather helped her to commit suicide and to carry out the death penalty she sentenced herself to. I did it to wash with her blood the family honor that was violated because of her and in response to the will of society that would not have any mercy on me if I didn't.…" The desire to end communal shame can cause families to go to extreme lengths. The al-Goul family, for example, spent six years searching for their daughter Basma who had fled after her husband accused her of infidelity. Despite her departure, contempt for her family kept spreading in the crowded Jordanian village where a women's chastity is everyone's business. Because of her alleged infidelity, villagers ostracized her parents, deemed her eight sisters unmarriageable, and taunted her five brothers on the street.

The prevailing view that devalues and belittles women is derived from sociocultural factors that are justified by a distorted and erroneous interpretation of religion, especially of Islam. Victims are killed by their fathers, husbands, brothers, cousins, or sons; and in communities where crime is persecuted, the younger the killer, the lesser the punishment. Women of the family (mothers, sisters, and relatives) often define the killing and even help set it up.

Legal Dimension of Honor Killings

Though honor killing crimes are widely known to be underreported, the UN Population Fund estimates that more than 5,000 women and girls are killed for reasons of honor each year. The majority of such killings take place in Pakistan, Jordan, and Turkey, according to UN reports. While on location in 2003, *National Geographic* documentarian Michael Davie estimated that at least three women were victims of honor killings each day in Pakistan. In some countries, the acts are considered legal. For example, state penal codes such as Article 340 of Jordan, Article 562 of Lebanon, Article 548 of Syria, Article 153 in Kuwait, Article 237 in Egypt, Article 309 in Iraq, Article 334 in the United Arab Emirate, Article 70 in Bahrain, Articles 418–424 in Morocco, and Article 252 in Oman provide exemptions from any punishment for all those who kill female family members who commit adultery, labeling male killers as acting in a "fit of fury" rather than committing a murder. In Saudi Arabia, the Sudan, Iran, Pakistan, and Qatar, sanctions under Shari'a law provide similar exemptions.

Honor Killings in the European Union

Increasingly, incidents of honor killings have begun to take place across Europe. According to the Swedish women's advocacy group Kvinnoforum, honor killings remain hidden from public view and are limited to immigrant populations. Such notions are echoed by Scotland Yard, which listed more than one hundred murder investigations as suspect honor killings in 2004, involving women from Turkish, Middle Eastern, and South Asian backgrounds. In 2005, German police agencies reported 47 honor killings of Muslim women across the country. In many cases, the reactionary idea of cultural relativism is used to justify women's victimization and to excuse Islam as a backward tradition within Europe. Thus, Europe's strong emphasis on cultural relativism within the mainstream media and intellectuals' attempts to explain such murders as part of the prevalent patterns of domestic violence against women in Western societies has led to a culture of tolerating intolerance.

Today with immigration and cultural exchange, basic changes occur not only in economic structures but in social relations as well, and these challenge the underlying principles of Islam as a social order. Immigration and world markets bring to Islam disintegration, upheaval, conflict, and contradiction, and the effect is felt mostly in home life and the structure of the family. Muslim women, especially in the European Union, live the conflict between traditions and the laws of emancipation in most European nations. The emergence of feminine initiatives and female self-determination challenges the central principle of the Muslim family, which emphasizes male supremacy and the systematic inhibition of females.

Honor Killings and Human Rights

The challenge to the central principle of the Muslim family from the emergence of feminine initiatives and female self-determination has

spurred a number of attempts to reverse legal sanctions of honor killings. In 1994, the UN's Commission on Human Rights appointed a special monitor of violence against women. UNICEF and the UN Development Fund for Women quickly followed suit. In 2003, Amnesty International launched a worldwide campaign to halt violence against women, linking honor killings to human rights. Cultural traditions change slowly, but these and other efforts to reduce violence against women and emphasize human rights in all cultures may eventually have positive outcomes.

Hospice, Contemporary

Hospice refers to a facility where terminally ill individuals and their significant others receive care. But hospice as a philosophy refers to care provided by an interdisciplinary team of professionals and trained volunteers to a terminally ill patient and their loved ones when the patient has a life expectancy of six months or less and the focus of care is on comfort, pain control (palliative care), and quality of life, rather than on curing the illness. The National Hospice and Palliative Care Organization estimated that 1.3 million patients received hospice care in 2006. According to the Hospice Foundation of America, there are more than 3,200 hospice programs in the United States, Puerto Rico, and Guam. Hospice programs are also common in Canada and Europe, with programs becoming more common in other parts of the world, particularly Africa, Asia, Latin America, the Caribbean, and the Middle East. This entry will describe the hospice philosophy of care, eligibility criteria, the relevance of advance directives, the components of hospice care, and legal/ethical issues related to hospice care.

Hospice Philosophy

Hospice philosophy is based on the idea that dying is a normal part of the life cycle, that opportunities for growth are possible when nearing the end of life, and that the quality of an individual's life is more important than the duration of one's life following the diagnosis of an illness for which there is no cure. Hospice views the patient and family as the unit of care and promotes patient self-determination, with patients and their families participating actively in the care planning process. Efforts to achieve a high quality of life stress the importance of physical, emotional, and spiritual comfort, the preservation of one's dignity while dying, and the ability to live one's final months and days in the least restrictive environment possible. Ideally, hospice care is provided in an individual's home, with friends and family providing care with the support of hospice professionals and trained volunteers. If this is not possible, hospice care may be provided in a specialized hospice facility, a hospital, or a skilled nursing facility. Hospice care has also been provided in hospice programs within prisons.

Components of Hospice Care

Holistic Care

The care plan for a hospice patient and his or her social support network provides holistic care, or care for the needs of the "whole person": physical, psychological/emotional, social, economic, and

spiritual. Physical care is palliative rather than curative, with an emphasis on comfort care and pain control while maintaining the highest degree of alertness possible. Psychological/emotional care focuses on meeting the basic psychological and emotional needs of the patient, assisting the patient and his or her support network in coping with the patient's impending death, and to facilitate communication about any unresolved issues that can be addressed. The hospice team will encourage and facilitate continued social interactions between the patient, his or her social support network, and the broader community until the time of the patient's death. Information about resources to diminish the economic stress that can result from the terminal illness of a family member is provided. Spiritual care assists the patient and family in finding meaning and purpose in the remainder of the patient's life, discussing beliefs about what happens after death, and assisting the survivors in coping with the death of the patient. Expressive therapies (e.g., drawing, painting, and writing) can be used with the patient as well as the family during the dying and bereavement processes. It is also becoming more common to use prescriptive music for the benefit of the patient and family by holding music vigils. Music thanatologists provide contemplative music played with harp and voice. Following the patient's death, bereavement follow-up services are provided for at least one year. These services range from telephone contact, cards and notes, individual and family counseling, online support services, grief support camps for children and teenagers, and public remembrance services.

Interdisciplinary Care Team

Hospice care is provided by a team of professionals that includes a physician/hospice medical director, a registered nurse, a social worker, and a chaplain or other counselor. Ancillary team members include a bereavement counselor, a home health aide/homemaker, a pharmacist, and volunteers who assist by providing emotional support, direct personal care, respite to the caregivers, doing light housekeeping, running errands, or working in the hospice office. Other professionals may be consulted, including medical specialists, dieticians, occupational and physical therapists, and complementary therapists (massage therapists, expressive therapists).

Eligibility and Payment for Hospice Care

In order to be eligible for hospice care, a physician must certify that the patient's life expectancy is six months or less if the illness runs its normal course and that the patient is choosing palliative care (comfort care) rather than curative care. Common diagnoses of hospice patients include but are not limited to those dealing with the end stages of AIDS, ALS (Lou Gehrig's disease), Alzheimer's disease, cancer, heart disease, kidney disease, liver disease, lung disease, multiple sclerosis (MS), and Parkinson's disease.

Hospice care is covered by most health insurance plans, HMOs, and managed care organizations. Medicare, a federally funded program available to individuals 65 years of age and older or to individuals with disabilities, also has a hospice benefit. To qualify for financial reimbursement, the hospice program providing care must meet the Medicare criteria for hospice care reimbursement. Individuals with limited financial resources who are uninsured or underinsured may be eligible for Medicaid, a joint federal-state program. Information about Medicaid-eligible hospice programs within a particular state is available from the state Medicaid office. Additional financial assistance for medical expenses may be available from local civic, religious, or charitable organizations.

Legal and Ethical Issues

According to the American Health Lawyer's Association, there are numerous legal issues that arise when an individual is facing a life-limiting illness. Estate planning should be done with the assistance of legal counsel, and families should be aware of legal issues relevant to the provision of end-of-life care. Many of the legal issues related to the provision of hospice involve requirements for the licensing of hospice programs and medical professionals, as well as compliance with regulations to qualify for third-party payment for hospice services. However, several legal issues relate directly to the rights of patients during the process of dealing with a terminal illness.

Due to the Patient Self-Determination Act, a federal law passed in 1990, patients receiving services from health care institutions that receive Medicare or Medicaid funding must be advised in

writing of their rights under existing state law to complete advance directives—oral and written directives describing a person's wishes regarding medical care—that are used in the event that a person cannot speak for himself or herself. Advance directives for hospice patients typically include a do not resuscitate (DNR) order. An individual can designate a trusted relative or friend to make decisions on his or her behalf (e.g., a health care proxy, durable power of attorney for health care, or medical power of attorney) or prepare written documents that record one's wishes under various circumstances (e.g., a living will). It is important to identify which type of advance directive is considered a legal document in one's state of residence.

Several other legislative efforts have advocated for the rights of the terminally ill. In 1989, the National Conference of Commissioners on Uniform State Laws drafted the Uniform Rights of the Terminally Ill Act, which has been passed by many individual states. This Act allows an individual to leave instructions for a physician to withhold or withdraw life-sustaining treatment in the event the individual has a terminal illness and is unable to participate in medical treatment decisions. Some states, such as Michigan and Oregon, have special state laws that relate to "death with dignity." The Michigan Dignified Death Act (MDDA) requires physicians to inform terminally ill patients about their right to choose hospice care. Patients with terminal illness have rights and choices under the MDDA. The law also gives immunity to physicians from civil and administrative penalties for prescribing controlled substances. The Oregon Death with Dignity Law, originally passed in 1994 and defended before the Supreme court in 2006, carries individual rights one step further, providing terminally ill patients with the right to request assistance in dying from a physician under specific legally defined criteria. "Physician-assisted suicide," which is only legal at the present time in the state of Oregon, is an extremely controversial legal and ethical issue. Many hospice advocates strongly believe that physician-assisted suicide would not typically be requested by a terminally ill individual who is receiving proper end-of-life care and therefore should not be a legal option for anyone. Although not a routinely used option, physicians may utilize palliative sedation (also known as terminal sedation) to relieve symptom distress of terminal restlessness and agitation during the last hours or days of a dying patient's life. The doses of these sedative drugs are titrated to maintain the patient's comfort without compromising respiration or hastening death.

A variety of ethical issues are equally relevant to hospice care. These issues are not laws, but principles that guide the work of health care professionals when assisting patients and their families with the provision of end-of-life care. These issues include communication with terminally ill patients, withholding and withdrawing treatments, the use of artificial nutrition and hydration, ethical issues related to research, and the issue of access to hospice care.

Sharing bad news with a patient and his or her family is never an easy task, and health care professionals must carefully balance the right of any patient to a full and honest explanation of his or her situation with factors such as issues of patient competence, a patient's right to decline information, and religious or cultural norms that influence how or to whom information about a diagnosis or prognosis is delivered. Concerns about diminishing hope must be weighed in relation to the potential harm that can be caused by withholding information or the loss of trust that may result when a patient learns the truth. Providing information about hospice care as an option in a timely manner is crucial because referrals in close proximity to the time of death prevent hospice care from being fully and effectively implemented. Time is required to achieve the maximum benefit of hospice care to the patient and family.

According to the International Association for Hospice and Palliative Care, the appropriateness of offering or withholding a particular treatment to a hospice patient is determined by balancing the possible benefits with the potential risks of the treatment, keeping in mind that therapy with no chance of benefit can never be justified. If a treatment will merely prolong the dying process without enhancing the patient's quality of life, it is probably best withheld. However, this decision is often a difficult and complex one that must be determined by the unique circumstances of the case that are carefully considered during discussions involving the hospice team, the patient, and the family.

Families are often distressed when a loved one stops eating and drinking because it is never

comfortable to imagine a loved one being thirsty or "starving to death." Decisions about interventions related to artificial nutrition and hydration should be based upon their ability to restore or enhance the quality of life in relation to the potential for negative side effects. In-depth discussion about the pros and cons of these interventions must occur, and unless quality of life can be restored or enhanced without the occurrence of detrimental consequences, these interventions should not be done.

Clinical trials—experimental research—may be open to participation by individuals with a terminal illness. If the goal of the clinical trial is to enhance quality of life rather than to seek a cure for the illness and the potential for harm is low, it would be appropriate for a hospice patient to participate. Health care professionals have an ethical responsibility to protect hospice patients from participating in studies that are not in their best interests, while allowing them the freedom to participate in research activities that may preserve their ability to contribute to society in meaningful ways.

Ideally, access to hospice care would be equal to all regardless of where people live, their race, religion, cultural beliefs, language, age, financial means, or their diagnosis. A 2003 Hastings Center Report on access to hospice care notes three specific areas where the most powerful barriers to access exist: (1) laws, policies, and regulations affecting the organization, financing, and delivery of hospice care; (2) attitudes and practices of health care providers, including referring physicians, who are the gatekeepers of the system; and (3) misunderstanding, misinformation, and stigma against hospice by consumers. Living in a largely death-denying society places many barriers in the way of timely referral to hospice care.

During times of concern about economic resources, it is reassuring that research has demonstrated the cost-saving benefits of hospice for Medicare and other insurance programs. However, economically disadvantaged individuals who lack health care coverage may not have access to professionals who can help them navigate the system to gain resources for end-of-life care. In addition, current policies regarding the hospice cap will need to be examined by federal policymakers and legislators. The National Alliance for Hospice Access is actively advocating for Congress to modify the aggregate hospice cap, which would ensure that patients receive care for as long as they are eligible and that hospice programs are able to survive financially.

The challenge of meeting the need for end-of-life care is anticipated to rise due to the projected demographic shift in the population of seniors in the United States to over 69 million by the year 2030. The pursuit of a "good death" by baby boomers who are aging during a time of increased awareness of the benefits of hospice care will place great demand on the ever-growing number of hospice programs. Gaining knowledge about this option for end-of-life care will facilitate an individual's ability to access these services in a timely fashion, making every day count when one's remaining days in this life are limited.

Hospice, History of

Caring for the dying has been a human responsibility throughout recorded history. The word "hospice" comes from medieval institutions that offered practical and spiritual assistance to pilgrims on their way to the Holy Land. In the late 19th century, the Irish Sisters of Charity applied the term to those nearing the end of life's journey when they opened Our Lady's Hospice in Dublin, Ireland, and, later, St. Joseph's Hospice in London, England.

Subsequently, the word "hospice" has come to designate both a philosophy of care and programs specializing in end-of-life care. In this sense, hospice services are designed primarily to provide care for those who are dying or who have no reasonable hope of benefit from cure-oriented interventions, along with their family members.

Founding of the Modern Hospice Movement

Cicely Saunders (1918–2005) led the establishment of the modern hospice movement. After training as a nurse, a chronic back problem prevented her from functioning in that role. Saunders then retrained as a medical social worker and took a position in an oncology unit at St. Thomas's Hospital in London.

Meeting and eventually falling in love with an agnostic Polish Jew who had inoperable cancer helped Saunders crystallize some of her ideas. David Tasma was 40, separated from his family and country, in great physical pain, lonely, and dying after what he thought of as an unfulfilled life. Reflecting on his situation spurred Saunders to ask what she could do to relieve the suffering and meet the needs of others like him.

As her interests matured, Saunders volunteered at St. Luke's in Bayswater, a well-established home for the dying. Here, she noted that pain-killing drugs were given at regular intervals instead of waiting until the pain returned. Also, whenever possible, injections were avoided and drugs were given orally, a method that was easier for patients and for family members caring for patients at home. These basic principles later became fundamental in hospice care.

When Saunders shared her desire to work with dying patients with a physician friend, he told her there was much to learn about pain control and the way to do it was to study medicine because it was doctors who desert the dying. She soon began studies that led to her medical degree. After qualifying in April 1957, Saunders obtained a research scholarship in pain research at St. Mary's Hospital and began to implement her ideas at St. Joseph's Hospice, Hackney. Before long, she determined to organize a body of like-minded supporters, develop a plan for an independent hospice facility, raise money, purchase a site, and build the new facility.

St. Christopher's Hospice and Further Developments in England

St. Christopher's Hospice in southeast London opened in 1967 as a purpose-built, inpatient facility designed to implement the new goals of excellence in clinical practice, research, and education in care of the dying. Although a private charitable foundation independent of the National Health Service (NHS), St. Christopher's maintains good relations with the NHS and receives funding for patients transferred from NHS hospitals.

Like many early hospice programs, St. Christopher's primarily serves patients with far-advanced cancer, but has always accepted some individuals with motor neuron and other diseases. For everyone, care is addressed to whole person, including physical, psychological, social, and spiritual dimensions, and to their family members.

Subsequent developments of the hospice movement in England took many forms. They include additional free-standing, inpatient hospice facilities (often purpose built); other inpatient hospice facilities built with private money on the grounds of NHS hospitals and then operated by the NHS; palliative care or continuing care inpatient units within some NHS hospitals; hospice home care teams developed to support the work of general practitioners and district nurses; hospital support or consultation teams to advise on the care of the dying in acute care hospitals; and hospice day care programs.

Hospice Care Worldwide Outside England and North America

It is difficult to briefly summarize the situation of hospice care around the world. One estimate is that early in the 21st century, there are hospice and/or palliative care initiatives in 115 countries. Where these initiatives are most robust (e.g., North America and Western Europe), there are well-established hospice/palliative care programs and services, along with national, regional, and specialist professional organizations; widespread exchanges of information (e.g., through the Hospice Information Service at St. Christopher's, publication of books, articles, and journals, and conferences); and the creation of teaching posts in palliative medicine. Elsewhere, there are problems in establishing and funding services, integrating those services with mainstream health care in the local areas, establishment of necessary governmental policies, confronting professional and social attitudes (e.g., regarding fears of addiction), adequate availability of medications (e.g., opioids), workforce underdevelopment, and coping with unique problems (e.g., poverty in many countries and struggling with the scale of HIV/AIDS in areas like sub-Saharan Africa). For about 25 years, the World Health Organization has sought to foster hospice/palliative care, improve professional education in this field, remove legal sanctions against opioid importation and use, and disseminate core principles of pain management. Nevertheless, it still seems that where the need is greatest, resources are least available. Unrelieved suffering is common and the scale of the problems faced by dying people around the world is increasing.

Hospice Care in Canada

In Canada, palliative care services were first developed at St. Boniface General Hospital in Winnipeg and at the Royal Victoria Hospital in Montreal in 1974. These services typically included an inpatient unit that is based in a large acute care teaching hospital, a consultation service, a home care service, and a bereavement follow-up program. Subsequently, a broad variety of nearly 500 programs and services offering "hospice palliative care" have been developed across Canada, along with several provincial associations and the national Canadian Hospice Palliative Care Association (www.chpca.net).

Hospice Care in the United States

In the United States, hospice care began in September 1974 with a community-based home care program in New Haven, Connecticut. From this modest beginning, hospice care has spread across the country. In 2005, the National Hospice and Palliative Care Organization (www.nhpco.org) estimated there were 4,160 operational hospice programs in all 50 states, the District of Columbia, Puerto Rico, and Guam.

Hospice programs in the United States are organized in many ways. Most are independent, free-standing agencies; others are hospital based, divisions of home health agencies, or based in long-term care facilities. Approximately two-thirds of hospice programs in the United States are nonprofit in character; the remainder are for-profit or government organizations. Nearly one-fifth have their own inpatient facility.

In 2005, American hospice programs served over 1,200,000 patients. Approximately 800,000 of these individuals died while receiving hospice care—roughly one-third of all Americans who died that year. Over three-quarters of all hospice patients who died were able to die in a place they called home—a private residence, a nursing home, or other residential facility.

In the United States, hospice programs originally cared primarily for elderly cancer patients, but as the movement has developed, hospice principles have also been applied to care for people with AIDS, motor neuron diseases (e.g., amyotrophic lateral sclerosis, ALS or Lou Gehrig's disease), Alzheimer's disease, and other life-threatening

conditions such as end-stage heart, lung, or kidney disease.

American hospice programs provide bereavement care to an average of two family members per hospice patient. In addition, most American hospice programs provide bereavement services to their communities, with community members receiving nearly one quarter of all hospice bereavement services.

The Hospice Medicare Benefit

In 1982, hospice funding in the United States was approved as a Medicare benefit. Admissions criteria typically required a diagnosis of terminal illness, a prognosis of fewer than 6 months to live, and the presence of a primary caregiver in the home. Medicare reimbursement is organized in four basic categories of services: (1) regular, daily home care; (2) general inpatient care; (3) short-term respite care; and (4) continuous in-home care (providing the presence of a trained hospice staff member in specified blocks of time). Each category of services has a stipulated reimbursement rate, typically adjusted to take into account differential costs over time and in different geographical areas.

The Medicare hospice benefit pays for over 80% of hospice services (other hospice funding sources include private health insurance, Medicaid, and charitable donations). The benefit emphasizes home care and shifts reimbursement from a retrospective, fee-for-service basis to a prospective, flat-rate basis. Thus, a hospice program receives the amount specified in the rate category for each day in which a dying person is enrolled in its care, regardless of the services it actually provides to that person on any given day.

All monies provided under the Medicare hospice benefit (except those paid to an attending primary physician) go directly to the hospice program, which is responsible for designing and implementing individual plans of care. No service is reimbursed unless it is included in the plan of care approved by the interdisciplinary hospice team. That gives the hospice program an incentive to hold down costs and only to provide care relevant to the needs of an individual patient and family unit.

The Medicare hospice benefit, which is now a model for other forms of reimbursement for U.S. hospice services, is a desirable option for individuals who qualify. The benefit is available in all Medicare-certified U.S. hospice programs (nearly 94%). It is broader than other Medicare benefits and is intended to cover all costs of the care provided. Although the benefit does incorporate upper limits on reimbursement to a hospice program, these are expressed in terms of program averages and total benefit days for which the program will be reimbursed, not in figures that apply to any particular individual. Once a person has been accepted into a Medicare-certified hospice program and while continuing to qualify for services, the law prohibits involuntary discharge. Hospice care is also covered by Medicaid in 43 states and the District of Columbia, as well as by 82% of managed care plans and most private insurance plans.

Hospice Care for Children

Programs of hospice and palliative care for children, adolescents, and their family members have taken many forms since the early 1980s. In England, Helen House, an eight-bed facility with four family apartments built on the grounds of a convent in Oxford, began serving children with life-shortening conditions and their families in November 1982, offering a "home away from home" for respite and end-of-life care. In February 2004, Douglas House, a seven-bed facility on the grounds of Helen House, became the world's first "respice" for people 16 to 40 years of age.

Earlier in the United States, in the mid-1970s, Dr. Ida Martinson, a nursing faculty member at the University of Minnesota, developed a home care program for dying children using volunteer nurses in Minnesota and parts of Wisconsin. This program demonstrated that many seriously ill children want to be at home with their families, even when their illness is far advanced; these children can be cared for appropriately in the home setting; and many family members, including parents, siblings, and other relatives, can benefit from being involved in care when guided and supported by knowledgeable professionals.

Canuck Place Children's Hospice in Vancouver, Canada, and George Mark Children's House in San Leandro, California, were the first inpatient facilities to offer hospice care for ill and dying children in North America. Both Canuck Place (since November 1995) and George Mark Children's

House (since April 2004) offer respite care, transitional care between home and hospital, and end-of-life care specially designed for children with progressive, life-limiting conditions.

Children's hospice services have also been sponsored by other community and institutional sources, as well as by some adult hospice programs in the United States, such as Daniel's Care at Hospice of the Bluegrass in Lexington, Kentucky, and the Child and Family Program at Hospice of the Florida Suncoast in Pinellas County, Florida. In addition, some institutions have developed specialized prenatal hospice programs (offering support and care to parents and siblings when a fetus has died in the womb) and neonatal hospice programs that employ hospice and family-centered principles of care for infants born with incurable conditions that are incompatible with life or for infants who die suddenly and unexpectedly in a neonatal intensive care unit (NICU).

Hospice Care and Palliative Care

Hospice care is a form of end-of-life care designed to minimize sources of pain and distress, improve quality of life, and offer opportunities for growth. Both the hospice movement and its philosophical principles have helped stimulate other forms of specialist palliative care, such as consultative services in academic medical centers and other hospitals in the United States that focus on relief of distressing symptoms and on the primary role of the physician. These programs represent efforts to manage pain and other distressing symptoms with or without reference to their origin or their relationship to dying and death.

Humor and Fear of Death

It is useful to divide a discussion of humor and the fear of death into three sections—humor where certain death is imminent, humor where there is a high risk of death due to circumstances or occupation, and humor and the everyday fear of death that lurks somewhere at the back of each individual's mind, even when safe and healthy.

Humor in the Face of Imminent Death

Anthologists are fond of quoting humorous "last words" by someone whose illness is known to be fatal or who is about to be executed. Such humor may be seen as a display of courage and indifference, possibly one that a particular society expects, encourages, and admires, at a time when the fear of death is reinforced by its immediacy—or as simply whimsical by its inappropriateness.

King Charles II of England said to his courtiers when dying in 1685: "I am sorry, gentlemen for being such a time a-dying."

Voltaire, when asked on his deathbed to forswear Satan, said: "This is no time to make new enemies."

It is an even more marked phenomenon when professional humorists die. When Edward Gwenn, the English actor, was dying in 1959, someone said, "It must be hard." He replied, "It is but not as hard as farce."

Lytton Strachey, dying in 1932, said: "If this is dying, I don't think much of it."

Witty men manage witty endings, but the electric chair induces bad puns. They are funny mainly because of the circumstances, of the forced cheerfulness at a fearful time. Perhaps it is a bid for a cramped immortality in the reference books.

George Appel, about to be executed in the electric chair in New York in 1928, said: "You're about to see a baked appel."

James French, when about to be executed in the electric chair in Oklahoma in 1966, said: "How about this for a headline for tomorrow's papers? French fries!"

Mocking Others' Fear of Death

There is an even nastier side to this, the mocking humor that has been employed by others of the visible fear exhibited by an individual facing death, particularly if they belonged to another race or religion defined as "other." Sometimes it relates to a real event, sometimes it is just a joke. It may be tasteless, but it is a genuine form of humor and was experienced as such by those using it and receiving it, which is the only test. Humor is not necessarily good humored.

According to author Sebag Montefiore, at a dinner to celebrate the foundation of the *Cheka* (Soviet secret police) held just a few weeks after Grigory Zinoviev had been executed, Karl Pauker, Stalin's court jester, acted the scene of Zinoviev's pleadings and death. There was great merriment and much applause. Pauker was dragged back into the room by two others pretending to be guards. He mimicked Zinoviev's terrified cries of "For God's sake call Stalin." Pauker, who was a Jew himself, imitated Zinoviev raising his arms to the heavens and crying, "Hear oh Israel the Lord is our God, the Lord is one." Stalin enjoyed it so much that Pauker did it again. Stalin laughed so much he felt sick and gestured at Pauker to stop.

Fear of death may also take the form of jokes or humorous narratives about those whose fear of death has led them into cowardice or disorder in the face of danger. Mockery of the excessive fear displayed by others facing death is not only a facet of popular culture, but has been skillfully used by noted playwrights as diverse as William Shakespeare and Peter Schaffer and novelists such as Charles Dickens, Anatole France, and Jaroslav Hašek.

Humor in the Face of Danger of Death

A common form of humor associated with those whose tasks regularly expose them to the risk of death is a morbid one that makes light of death and its fears. It is well seen in the songs composed and sung by British soldiers in World War I when a million of them died, fighting in the trenches.

(Tune: Salvation Army hymn)
If you want the old Battalion
We know where they are
We know where they are.
They're hanging on the old barbed wire.
We've seen them.
We've seen them.
Hanging on the old barbed wire
The bells of hell go ting-a-ling-a-ling.
For you but not for me. . . .
O death, where is thy sting-a-ling-a-ling.
O grave thy victor-ee.
The bells of hell go ting-a-ling-a-ling.…

The tradition continued in World War II, notably in the Royal Air Force (RAF), a branch of service with a high casualty rate. These are songs about the death of comrades and friends, a death that may well be experienced by the singers tomorrow, something of which they were well aware. We do not know who composed them. Indeed they are a collective product certainly sung together, probably put together piecemeal. It is worth noting that they parody religious and sacred themes in a profane way. There are humorous songs, too, about death in other dangerous occupations, such as fishermen working out at sea. Singing them together may help group morale and solidarity in the face of a high risk of death.

It should also be kept in mind that in English-speaking countries there is a social expectation that humor will be used in the face of danger. Memoirs recall the joke that broke the tension, for it is seen as important enough to be recollected and preserved. It is seen as culturally appropriate and, in time, becomes part of an established tradition that, in turn, induces similar behavior. Sometimes the humor is given far greater importance and frequency in retrospect than it had in practice, partly because humor is pleasantly memorable and partly because such memories feed our self-respect and the respect of others.

There are also good studies of how humor is used in the face of danger and death to ensure reliability and cooperation under circumstances where an individual's giving way to an understandable fear or indeed to recklessness would endanger the lives of others. We can see this in accounts of the use of jokes and comic insults in the inducing groups, such as ironworkers or astronauts, to manage their fears and act as a coherent team in the face of danger.

Popular Humor and Distant Death Known Only From the Mass Media

During the last half of the 20th century, a new form of popular humor developed about fearful events resulting in death These were the waves of joke cycles about disasters, such as the loss of the American space shuttles Challenger and Columbia, the sinking of the British ferry Herald of Free Enterprise, the crashing of the Concorde in Paris, and the fatal fire on the oil rig Piper Alpha. There were also jokes about the sudden death of celebrities, from John F. Kennedy to that of his son John-John and from Mrs. Gandhi to Princess Diana. The jokes reflect the realities of modern societies in which sudden early death before the life cycle has been completed is rare and yet when it happens, it is the subject of intense attention by the broadcasters. They compete to provide pictures of disasters, and their reporters try to instill into their viewers and listeners the sense of fear of the sight of death they believe they ought to be conveyed. But viewers are sitting at home in comfort and safety while the anguished messages are sandwiched between trivial advertisements and quiz shows, which creates a great deal of incongruity and hence laughter.

What's the favorite drink at NASA?
Seven-Up with a splash.

Why did Mrs. Indira Gandhi change her deodorant?
Because her right guard was killing her.

What did the mortuary attendant sing as he packed Diana and her boyfriend into body bags?
Zippedy-Dodi, Zippedy-Di.

Such humor is not callous nor is it a form of coping, for the joke tellers have no direct experiences to respond to and overcome. Rather, it is mocking a fear of the face of death experienced by media professionals who are now trying to sell it to the public. It is quite different from the humor that accompanied an Irish or Newfoundland wake or Mexico's Day of the Dead. This is the humor of societies where death is more familiar. The form that humor takes in the face of the fear of death depends on the degree to which a society denies and hides death or accepts and embraces it. Even in the latter case, it is difficult to know the extent to which the humor of death is related to the fear of death rather than to grieve past deaths or the way the individual's death temporarily disrupts the social order. It is customary, indeed compulsory, to speak of death in a quiet, respectful, and solemn way. Humor is nearly always a transgression, even at times an inversion of social rules that demand certain attitudes and ways of speaking, and the case of death and the fear it inspires is one more instance of this.

A possible source of modern fears of death and their humor is the media-induced sense of foreboding about general risks due to modern technology, such as nuclear power stations, genetically modified crops, or new chemicals, even though these have generated very few deaths indeed. Sociologists have even spoken of the "risk society," the *Risikogesellschaft,* in which such fears are central to social and political life. Whether anyone other than a few activists is troubled in any immediate way by these fears may be doubted. Yet in the one case where there was a real risk, real precautions, and a real popular fear of death, there was again humor: This was the Chernobyl disaster when a socialist-built and operated nuclear power station spewed radioactivity into the atmosphere. In socialist Hungary, a country close to the Ukraine and Chernobyl and at that time a satellite of the Soviet Union, they joked:

What's the new shopping craze?
To save money, people are buying Kiev bread instead of fluorescent light bulbs.

What did the workers celebrate at the May Day parade in Budapest?
The radiant friendship between Hungary and the Soviet Union.

How was the May Day Parade in Kiev organized?

In rows. In the front row were the party activists, in the second were all the youth communist activists, in the third all the union activists, and finally all the radio activists.

Types of Fear of Death and Humor

The fear of death may be a fear of one's own death, fear of the death of a close relationship, or even simply fear of the sight of death. It may be a fear of the pain of dying or a fear of what happens after death. The former is less often a subject of humor (pain as such rarely is) and perhaps even less so in a society where the alleviation of pain through drugs, even to the point of inducing unconsciousness or accelerating death, has become usual. Rather, for unbelievers it is the fear of personal annihilation and for believers it is the fear of a bad reincarnation or the fear of the torments of hell or purgatory that are linked to humor. There are many forms of humor related to many different facets of the fear of death.

IMMORTALITY

Humankind's mortality and death generate reflections on immortality as a solution to the problem of death. In the following text, immortality will be analyzed in different types, the problem of immortality and personal identity/personhood will be explored, and arguments surrounding the value of immortality will be presented.

Types of Immortality

The immortality of humankind can be distinguished in two different types: (1) mundane immortality, where humans continue to exist forever without dying in the earthly world, and (2) transmundane immortality, where humans continue to exist forever in the earthly or transcendent world after dying. Transmundane immortality can be distinguished in personal, transpersonal, and impersonal immortality. Personal immortality implies that the person who existed before death continues to exist in some form after death. Transpersonal immortality implies that the person existing before death is transformed into another person after death. Impersonal immortality implies that the person existing before death is transformed into an impersonal existence after death that still in some relevant sense has a connection with the earthly person. This distinction is important to the question of the value of immortality and why immortal existence would be of comfort in the face of death, if indeed it is. It can be argued that if the problem with death is that *I* as a person dies, immortality would be a comfort to me to the extent *I* continue to exist in some relevant sense. However, what it is for *me* to exist in a relevant sense is open to a number of different interpretations.

Besides the different religious ideas around transpersonal or impersonal immortality, in terms of the migration of the soul into other people or creatures or by becoming part of the all-inclusive universe, we also find secular ideas about personal immortality that would not imply the continued existence of *me* in the normal sense. One concept related to Einstein's idea of time as a fourth dimension claims that we are immortal because every time segment of *me* continues to exist, forever, in the time dimension of our existence, and when we live our life we move consecutively through these different time segments. Hence, when I die, what continues to exist, forever or as long as time exists, is the former time segments of *me*.

Transmundane Personal Immortality

Within the perspective of a transmundane immortality, we find three basic types of personal immortal existence:

1. Humans continue to exist as nonbodily souls after death.
2. Humans' nonbodily souls continue to exist in new bodies after death.
3. Humans continue to exist as new unities of souls and bodies, where the soul is not a distinct entity separated from the body.

Transmundane personal immortality should confront two philosophical problems: the problem of personhood (i.e., what makes a human into a person) and the problem of personal identity (i.e., what makes a person at one time the same person at another time). When relating personhood or personal identity to only an earthly existence, death is seen as a radical change to a human's life that has to be dealt with.

Personhood and Personal Identity

Connecting personhood to a nonbodily soul that is unaffected by death and continues to exist after death will deal with both the problem of personhood and personal identity. This, however, presupposes a dualism or separation in humans between the soul and the body, giving rise to new philosophical problems. First, it has been questioned how a nonbodily soul could interact with a physical body. Second, important aspects of personhood, (i.e., how we experience the world and ourselves) seem intimately linked to us having a body to interact with the world through, and that our bodies are part of our personhood. Continued existence as a nonbodily person would then be either unimaginable or so radically different from our bodily existence that it would be difficult to claim we are the same person, which is a problem for personal identity.

Human's nonbodily soul continuing to exist in a new body would solve the problem of personhood to the extent it is a new physical body. If it were a different body (for example a nonphysical body), the problem of personhood would remain because it is difficult to imagine how such a body would give us access to the world. Keeping the nonbodily soul after death would only partly solve the problem of personal identity because the soul is only one aspect of the personhood in the combination of soul and body. It can be argued that receiving a radically new body (whether physical or not) will imply that the person before and after death is not identical. Moreover, the problem of interaction between soul and body will remain. The idea of humans continuing to exist as a new unity of body and soul after death would solve the problem of interaction but, on the other hand, emphasizes the problem of personal identity because it is a *new* unity of body and soul.

Mundane Personal Immortality

Mundane immortality implies that humans cannot die (necessary immortality). However, mundane immortality could also imply that humans can die, but, as a matter of fact, do not die (contingent immortality). Both of these interpretations should be distinguished from radical life extension, which the advances in biomedical research have raised as a real possibility, where human life is prolonged but we will be prone to death and will die eventually.

Necessary immortality would radically change the features of human existence in many ways, not only in the sense that human existence is prolonged into eternity. The fact that we are mortal and will eventually die and that we think of ourselves as mortal is taken to be intimately related to what it is to live as a human being. The vulnerability that makes us mortal will enable us to experience human emotions like suffering, which, in turn, is a precondition for empathy toward other people. If we were immortal, part of this vulnerability would have to be lacking, something that would change both our individual lives and social interaction with other humans. Likewise, it is argued that human beings arrange their life and have an attitude toward life that incorporates this knowledge that life is limited. This reflects how we relate to our human projects and also to essential features of human life, such as generational change.

Contingent immortality would solve the first problem of human vulnerability. However, it would still change the features of human life if life was not actually limited in time. Moreover, if we can die and still live forever, we need to live in an environment in which we do not encounter any risks that would jeopardize our lives. That is, in the world we presently live in, we will statistically die because we will eventually encounter one of the risks that will make us die. Such an environment would in itself be a radical change for human existence. A life extension would not imply such a radical change of human existence. This idea rests on the assumption that human aging could be slowed and the major deadly diseases could be cured, thus increasing the life span of humans. Even so, humans living in a world similar to the one we inhabit, and being vulnerable to death, would eventually die.

Problems of Mundane Immortality and Radical Life-Extension

The question of whether we have reason to pursue extended life, even into immortality, is related to the question of whether death is bad or not. If death is bad, as far as it robs us of future worthwhile life, extended life would be good until we arrive at the point where future life is no longer worth living. There is no principled reason why this would arrive when we presently die, and some have argued that this could give us reason to pursue continued life into eternity. A classical argument raised against this position is that if human life is extended far into the future, humans would eventually arrive at a point where life would become irrevocably tedious. That is, to preserve personal identity, the amount of change humans could go through is restricted. In order to avoid tediousness, humans would have to move through a series of different persons, not implying that a definite person is immortal. Here it is implied that such tediousness means that life is not worth living and humans would then be better off dead.

Several attempts have been made to counter this argument, focusing on different underlying assumptions. It can be argued that while humans' existence is more plastic and less static than assumed by the argument and with eternal existence, humans could find an infinite number of alternatives that could be explored and thereby avoid boredom. In regard to personal identity, it can be argued that we need not be identical at every point in time; it is enough that there is a continuity between the *me* at different consecutive times. In the same way we do not demand that we are identical when we are 20 years old and 80 years old, it is enough that we are relevantly identical today and tomorrow. It can also be argued that the memory of humankind is too restricted to encompass an eternal life, and hence would be forgetfully ignorant of the repetitious life we live. Likewise, the argument rests on a restricted view on what gives life meaning or value, focusing only on the subjective component. If life can have value regardless of how we feel about that life, even immortal life could be worth living. Moreover, even if true immortal life would result in meaningless life, perhaps life could be radically extended before this happens.

Now, even if immortality or radical life extension would benefit the individual person, it could constitute problems for society as a whole. These problems are of three different but related types:

1. Problems with overpopulation if people's lives would be prolonged and new people are born
2. Problems with creativity and development of society if older generations would not be replaced by newer generations
3. Problems with social justice if immortality would only be open to the few

A way to solve the problem of overpopulation would be to block the possibility to have children for people who are immortal. Of course, this could lead to problems of creativity and renewal. If trying to solve both of these problems by only allowing a few people to become immortal, then we face the problem of social justice.

In the end, the quest for immortality to avoid that *I* die, would seem to face us with philosophical problems implying that immortality in the real sense cannot be achieved without a radical change of who *I* am; a change that would not comfort *me* in the face of death. The more realistic quest for radical life extension is to confront the moral problems that will outweigh the benefits of prolonged life.

INFANTICIDE

Infanticide is the killing of an infant, a child under the age of one year. Although the perception of infanticide holds some cultural variation throughout the world, the English Infanticide Act (1938) is clear; infanticide is defined as the killing of a child within 12 months of birth by the mother of the child.

This perspective of English law is also found in the legislation of some of the states of Australia, such as New South Wales, Western Australia, Tasmania, and Victoria. In Canada, under the Criminal Code of Canada, Part VIII: Offences Against the Person and Reputation Section 233, "A female person commits infanticide when she causes the death of her newly born child." In Asian countries, infanticide is not always the result of action by the mother. Rather, the decision for the killing may well be communal, such as a decision of the village, extended family, or the husband. Very few Asian countries, such as China, have clearly stated legislation prohibiting infanticide and even those that do, such as India, have practical difficulties implementing the law. The United States has no specific infanticide legislation; rather, the killing of children is dealt within the wider context of homicide law. Offending mothers face potential execution, although in most instances convicted mothers are granted suspended sentences.

Many cultural and religious factors contribute to the practice of infanticide, and much has been written about the practice of infant killing within a cross-cultural context. Although the belief persists that some cultures, such as the Chinese, are more accepting of infanticide, it is much more likely that such perceptual differences and tolerant practice toward infanticide are attributed to the prevailing stressors of the time, including those due to traditional cultural mores, religious orientation, sexual inequality, economics, and differing or changing standards of individual rights. With improved education and a modern worldview, the modern Chinese are just as abhorrent of infanticide as any other culture. In the following discussion the reasons for infanticide are presented within a historical context and within the changing contemporary experience.

Infanticide in Historical Context

The practice of killing children can be traced to prehistoric times and religious literature, including the Bible, which provides many examples of infanticide. In ancient Babylonian and Chaldean civilizations, abnormal infants were thought to be the offspring of witches and animals and were left to die by the road. In what is perhaps the earliest practice of eugenics recorded, during the dominant period of the Greeks and Romans, and particularly among the Spartans, deformed or weak infants were readily killed. In the Biblical story, the child Moses may have been abandoned in the river as an act of attempted infanticide. Indeed the abandonment of Romulus and Remus at the fabled origin of Rome may also have been attempted infanticide. In ancient China, folklore describes the deadly struggles among the Emperor's concubines for his favor. Such struggles often were intricate conspiracies involving court officials and eunuchs plotting to kill the Emperor's offspring in an effort to manipulate the succession to the throne. Other stories tell of the kidnapping and killing of young infants in a quest for the elixir of immortality.

History reveals periods where child killing appears to be related to "religious" practice. Such sacrifices were offered to appease angry gods in exchange for a good harvest or in gratitude for victory in armed conflict. The Aztecs offered children in sacrifice to the Rain God Tlaloc. The Incas sacrificed the young in return for fertility. East African tribes sacrificed their firstborn for a bountiful harvest. The Bible, in 2 Kings 6:28, tells of the King of Israel agreeing to boil his son to provide food to relieve a famine resulting from a siege in Samaria by the King of Syria. This act is in many ways intertwined with the

notion that children are the property of their "household head," as found in the Roman doctrine of patria potestas. Taken to its extreme, a child's right to life lies in the hands of the household head, and in many ancient societies this paternal right is absolute. This paternal right is manifested in the decree of the king or emperor, the local chieftain, the village elder, the clan's elder, and, of course, the biological father. Even in modern times, this notion continues to dominate in some Asian and African communities where the child is expected to fulfill the wishes of their parents. In China, the ancient concept of "filial piety" proposed by Confucius embraces this concept, and children are expected to bow to the wishes of their parents. This Chinese version of patria potestas extends to modern times, where neighbors stand by watching a child be beaten to death by his or her parent for some perceived wrong the child committed.

With the development of the large urban communities and industrial economies, children and women ironically became even more dependent on the male provider and protector, and the practice of infanticide increased in the early phases of industrialization.

Over time and with the rise of Christianity and industrialization, a social climate emerged that caused unwed mothers to face both religious and social sanctions. The "Enlightenment" had not improved the plight of the unwed mother, but had added an extra layer of sanctions. **Unwanted newborns** were disposed of regularly. Abandonment, overlaying, and drowning became common methods used to kill infants. Overlaying is a situation where the young child dies of suffocation by the clothing and body of its mother while sharing the same bed. Such events were often reported as "accidents and tragic," but were suspected to be intentional suffocation by many doctors. Eventually the Catholic Church reacted, becoming the first institution to institute penalties by calling overlaying a sin. States reacted with the introduction of stiff penalties, and ideas relating to child advocacy spread; neighbors intervened thereby saving infants and children from death.

Legislating Against Infanticide

Early legislation introduced to punish infanticide was harsh; women found guilty of killing their newborn were often put to death. Sacking, a form of execution, was particularly barbaric. In sacking, the woman was placed into a sack that was tied and thrown into a river or sea. This practice spread everywhere and is frequently re-enacted in Chinese films and television dramas, although it appears to be used more as a punishment for adultery.

Russia was the first country to adopt a more humane attitude toward the problem of unwed mothers and infanticide. By 1888, all European countries except England had made legal distinctions between murder and infanticide by making infanticide punishable with more lenient penalties. Finally, in 1922 and later in 1938, England passed the Infanticide Act, which remains to this day. The 1938 law was improved and was the first time that the age of the child was extended to 12 months, which was an improvement on the 1922 act, which merely stated the "newborn." The introduction of the English law was perhaps a result of the frustration of the legal authorities of the day. Because of the frequency of unwed motherhood and the strong social taboos of the time, the reasons for the killing of an illegitimate child were not lost on the juries of the day. Frequently, juries refused to convict the mother despite the evidence of such an act of killing. Juries formed a view that the postnatal woman could not have formed the legally required mens rea (criminal intent). The authorities in England realized that the existing homicide laws were out of synch with the lay public, as it made no distinction between such "tragic" deaths and the other "heinous" crime of intentional killing. In a sense, infanticide legislation was a product of societal sympathy for women who were deemed to have been exploited and then abandoned by the child's father.

Another reason for the empathetic approach taken by juries was the nature of the evidence. In the 19th century, medical and forensic knowledge was in its infancy. The determination of live birth was by way of the "flotation test" method, which involved the removal of a lung or lung tissue from the dead infant and dropping this into a jar of water. If the tissue floated, it was deemed that the infant was born alive because there is air in the lungs that allowed the lung to remain afloat. This test was subsequently totally discredited but was nevertheless employed, and the results used as

evidence upon which countless numbers of mothers were sentenced to death.

Actus Reus and Mens Rea

The actus reus (guilty act) of killing of a child is clear and rarely a source of confusion. It is in the mens rea of the offender, namely the mother of the child, where many variations can be found. The English Infanticide Act (1938) provides the basis for discussion of the mens rea concept. The central premise of this piece of legislation is that " . . . the mind of the woman (mother), at the time of the act of killing, was imbalanced due to the effects of not having fully recovered from birth or by reason of the effects of lactation." In effect, the law provides a case for the offender (the mother) by deeming her to be mentally unsound and, therefore, incapable of forming criminal intent to kill. Thus, the perpetrator cannot be prosecuted to the fullest rigor of the law on homicide. In effect, the law on infanticide effectively limits the legal charge to manslaughter as opposed to murder. Furthermore, this legislation removes the need for the courts to deliberate the presence or absence of the mother's intent by presuming that she was mentally incapable of forming intent to kill. Supporters of the Infanticide Act argue that this is a sympathetic and humane piece of legislation that shows empathy for the many social and cultural taboos that may affect women, particularly those faced with an unwanted pregnancy. Opponents state that this legislation represents a death sentence for children who had the misfortune of being unwanted.

In modern society it is difficult to understand why a mother would kill her child; it is easier to conclude that she must be suffering from some kind of mental illness. The remedy for such an act is often the rendering of psychiatric care and rehabilitation. In contrast, fathers (or anyone other than the mother) involved with killing an infant will be charged with murder, with severe punishments if convicted.

In practice, the police, public prosecutors, and social workers effectively employ any evidence to support the assumption that the mother must have been mentally affected. One example is shaken baby syndrome, where a young baby is killed or suffers severe neurological damage as a result of violent shaking by an adult. One explanation for this act is attributed to the chronic stress and fatigue associated with child care, leading the caregiver to lose control and, during a period of intense frustration possibly triggered by incessant cries of the infant, violently shake the baby. Where this involves the mother, those sympathetic to her argue that the reason was her immaturity, emotional instability, and lack of support for a young, inexperienced mother. Others less sympathetic argue that it is a blatant act of violence intended to cause death or serious injury to a defenseless child.

Even in modern times, the crime of infanticide carries a certain amount of empathy if not social sympathy. Men thought to be irresponsible lovers are blamed for placing the vulnerable woman in such a desperate predicament. This applies equally in matrimony, where the husband may be blamed of his inadequate financial support and absent emotional assistance to his wife and children, such inadequacies being accepted as a "probable" cause of the mother's poor mental well-being, rendering her incapable of caring for her own child or killing her own child. When a dead child is found, an inquest is often held, but no formal charges, not even infanticide, are laid. The authorities prefer to use any possible suggestive evidence to label the child as a stillbirth.

Female Infanticide

A recent report by the United Nations highlights the epidemic of female infanticide. This epidemic is particularly prevalent in countries such as India, China, and Korea, but is found in many of the other Asian countries as well. In these countries, infanticide is a part of the cultural heritage of the past, in which a strong traditional view of male dominance continues to hold sway. Infanticide also is thought to be a product of a rapid improvement in economic status. The cultural ethos is that males are rightful heirs of not only family fortune, but also of the family's name. Females are looked upon as a burden upon the family's resources, as she will eventually be married and will then be expected to carry the name of her husband.

Many of the historically identified reasons for infanticides still prevail in the contemporary experience. In rural areas, where many of the people live in poverty, the "unwanted" female addition to

the family is resolved by killing the child. Scarce resources are saved for a male child. In countries such as China, where strict population control is exercised, the often stated "one child policy" (which began in 1979 and remains today) means that, for many families, the limited opportunity to have a child should not be "wasted" on a girl. The female child is deemed incapable of carrying on the family name and also not allowed to inherit the family land, for example. Hence, it is believed that many female newborns continue to be abandoned or killed shortly after birth.

Technology also indirectly plays a role in female infanticide. Given the nature of modern medical technologies, acts of female infanticides may be decreasing, but only because of options such as the early abortion of the female fetus. In urban India, for example, even without strict population control policies like those in China, the knowledge that the unborn fetus is female triggers anticipation and anxieties of required large dowries accompanying the marriage of a daughter, leading to the aborting of the female fetus or the killing of the newborn female if an abortion had not succeeded before the birth of the female child.

But nature has an innate way of dealing with the excesses of the human species. Female infanticide cannot be sustained or the human race will die. As it is, economists, politicians, and national leaders are beginning to highlight the potential biological and social consequences that sex selection, preference for a male child, and the subsequent imbalanced sex ratio that the strong desire for a male child can create. Indeed, this imbalance is already being witnessed in large Asian urban areas with a concomitant rise in deviant behaviors.

With education and an increased awareness of human rights and sexual equality, there is hope that infanticide will decrease in the future. Some evidence is available to support this contention and can be found in the increasing numbers of families that chose to have only one child regardless of the sex of the child. Other evidence points to existing monarchies around the world that appear willing to facilitate changes in ancient cultural rules and mores to allow for a female heir to continue the royal line.

Infant Mortality

Infant mortality is a subset measure of the construct morbidity, which itself is an estimation of the healthiness of a society. Characterized by variables that help to explain significant differences in infant death rates and incidence, part of the understanding of infant mortality is the construct of the death rate in a given population. As infant deaths under the age of 1 year has become relatively rare in societies that place major emphasis on maternal health, the infant death event assumes greater importance. The variables relating to infant mortality are discussed within the context of the general U.S. mortality rate.

Demographically the term *infant* refers to the child that is born alive and lives until he or she reaches the age of 1 year; that is, from birth through the 364th day of life. Some analysis also splits this time frame into the first 27 days (the neonatal period) and the last 337 days (the postneonatal period). Summative data for infant mortality based on the neonate and postneonate time frame

indicates that while the mortality rate has decreased since 1995 in both categories, mortality rates for neonates in 2004 and 2005 were 4.52 and 4.54 respectively per 1,000 live births compared to 4.9 in 1995. This rate means that 67% of all infant deaths occur during the neonate period. The leading cause of neonatal death is birth defects. Similarly, the rates for the postneonatal period decreased from 2.6 per 100 live births to 2.3 in 2004. The leading cause of postneonatal death is sudden infant death syndrome (SIDS). This last rate, 2.3, has been basically flat for several years.

Effect of Additional Live Births

When the Centers for Disease Control and Prevention (CDC) released the infant mortality data for the year 2002, it was noteworthy that for the first time since 1958, the mortality rate for infants had increased from 6.8 per 1,000 live births to 7.0. Subsequent analysis concluded that the major reason was an increase in the birth of very small or low-weight infants. Low weight at birth has been, and remains, one of the top three causes of infant mortality, and despite considerable progress being made in the care of very small infants, this condition remains a major predictor of infant death. The CDC indicates that the majority of babies born weighing less than 750 grams (1 pound, 10.5 ounces) will die before the end of the first year of life.

Infant Mortality Rates Over Time

Comprehensive data on infant mortality rates in the United States since 1915 are available. Cumulative analysis indicates that infant mortality has reduced by 93% since that time, while neonatal mortality has declined by 89%, and postneonatal mortality declined by 96%. The overall infant mortality rate in the United States for 2005 was 6.86. Based on data provided by the CDC, the infant mortality rates for the previous 10-year period are: 2004 (6.8); 2003 (6.9); 2002 (7.0); 2001 (6.9); 2000 (6.9); 1999 (7.1); 1998 (7.2); 1997 (7.2); 1996 (7.3); and 1995 (7.5).

However, there are significant differences observed between various racial, ethnic, and maternal age groups in the United States. Although these differences have always been significant, in more recent years the gap between black versus white infant mortality rates has widened. For the years 2002 to 2004, the data indicate the following infant mortality rates: black 13.5 per 1,000 live births; Native American 8.6 per 1,000 live births; white 5.7 per 1,000 live births; Hispanic 5.6 per 1,000 live births; and Asian American 4.8 per 1,000 live births. The racial/ethnic differences are still apparent when the age of the infant is considered. Neonatal mortality rates for black babies is 250% higher than for white or Hispanic babies, and postneonatal mortality rates for black babies are also 250% higher than white or Hispanic babies.

Further data indicate that women under the age of 20, or over 40, who give birth have the highest risk of losing their child during the baby's first year: under age 20, 10.1 per 1,000 live births; ages 20 to 29, 6.8 per 1,000 live births; ages 30 to 39, 5.8 per 1,000 live births; and age 40 and older, 8.6 per 1,000 live births.

Major Causes of Infant Mortality in the United States

Accounting for 68% of all infant deaths in 2005, the 10 leading causes of infant mortality in the United States were as follows:

1. Birth defects (congenital malformations and chromosomal abnormalities)
2. Low birth weight (disorders related to short gestation and low birth weight)
3. SIDS
4. Newborn affected by maternal complications of pregnancy
5. Newborn affected by complications of placenta, cord, and membranes
6. Accidents (unintentional injuries)
7. Respiratory Distress Syndrome (RDS) of newborn
8. Bacterial sepsis of newborn
9. Neonatal hemorrhage
10. Necrotizing enterocolitis of newborn

Over the last 25 years there has been little change in the top three causes of infant mortality, whereas the other top causes have frequently changed places. The mortality rate for birth

defects has decreased by 17% since 1996, which reflects major research efforts to treat defects, especially surgically, and to prevent them with education paradigms. Conversely, the death rate due to low birth weight has increased over the same period by 12%. The third highest cause of infant mortality, SIDS, has declined by 30% since 1996. The most likely reason for this change in mortality is based on the changed practice of positioning sleeping babies on their back. The rate for the fourth major cause, maternal complications of pregnancy, increased by 33% since 1996.

Impact of Public Health Measures on Infant Mortality

Research estimates that in 1900 the U.S. infant mortality rate was approximately 180 per 1,000 live births. Half a century later, the rate was 40 per 1,000 live births, after the use of antibiotics to treat many infectious diseases further reduced infant deaths. By the mid-1980s, the infant mortality rate was 10 per 1,000 live births. This dramatic change is associated with public health measures, notably water quality improvements including chlorination processes; the widespread use of vaccinations for polio, smallpox, and rubella; and sewage sanitation, the pasteurization of milk, and well baby clinics.

Infant mortality data offers an opportunity to consider the quality of life and general prosperity of a nation. The U.S. health care system spends more per capita than any other country, but it is not among the countries with the lowest rates of infant mortality. That distinction is given to a number of other nations, shown in Table 1 (pp. 602–603). Based on a 2007–2008 Human Development Report, these comparative data for the 1970 and 2005 period offer some important insights into the infant mortality phenomenon. One such insight is that, in general, infant mortality has significantly decreased throughout the world, or more specifically in those countries for which data are available. In some instances, such as the Scandinavian countries, Belgium, Japan, France, Spain, Italy, Greece, Korea, the Czech Republic, the United Arab Emirates, and Chile, for example, the decrease from 1970 to 2005 has been quite dramatic. These recent infant mortality rates show that a number of nations have lower infant mortality rates than the United States. These countries appear to share one important and common characteristic, universal/national health care systems that ensure the adequacy of prenatal care for all pregnant women, regardless of their ability to pay.

Access to Health Care

During the 20th century, major progress was achieved in the United States in reducing infant mortality, during both the neonatal and postneonatal periods. In spite of this achievement, the women of the United States still find their babies at higher risk than at least 20 other nations. Research conducted by the March of Dimes foundation indicates that nearly 4% of mothers receive no prenatal care and almost 11% of American mothers received inadequate prenatal care.

Informed Consent

Medical intervention and research trials often involve risk, and this risk can be substantial enough to include the death of the participant as one possibility. Even trials with medicines that are thought to have little potential for adverse consequences can lead to unexpected death because of the complex differences among people who are treated or who participate in clinical trials. This vulnerability is one of the more important reasons for the process of informed consent to be carried out with care, and improved through experience. Informed consent refers to an individual's act of acquiescing in an intervention or in research affecting the individual, without coercion and with full understanding of what is entailed by the intervention or research. The fundamental basis of the concept of informed consent is respect for people and respect for their autonomy—their right to self-determination. This concept has been particularly important in bioethics in the 20th and 21st centuries, and it undergirds the maxim that decisions about what is best for a person ought to be made by the one whose life is going to be affected.

The most important reason for the prominence of this concept in recent ethical thought is historical experience in which informed consent was not observed, and in which moral atrocities occurred. These historical events offer an important perspective from which to view the evolution of contemporary notions of informed consent. For example, the Nuremberg Code, which has provided a starting point for understanding the meaning and importance of informed consent, grew out of the trial of German physicians who conducted human experiments in Nazi concentration camps. All subsequent codes and systems of regulation related to informed consent derive in various ways from this code. The issue of informed consent was addressed and refined in several important subsequent documents, such as the Declaration of Helsinki adopted by the World Medical Association as a governing set of research ethics principles. This set of principles established the priority of human subjects' interest over those of science and society.

The U.S. Congress became increasingly concerned about informed consent during the early 1970s in part because of another historical event—the Tuskegee Syphilis Study. This involved poor black men who were not informed participants in the study and who were used as means to gain knowledge about the natural history of untreated syphilis. Though they were told about the fact that they had "bad blood," they were not told of the penicillin treatment effective against syphilis, a treatment that had become the standard treatment for the disease by 1947. As a result of the details of the Tuskegee study, the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research was formed. This led to the production of the Belmont Report in 1979, a report that built upon the principles expressed in the Nuremberg Code. This report embraces three principles that are now familiar and accepted as crucial for research involving human subjects, and which are vital to a robust notion of informed consent: respect for people, beneficence, and justice. For the purposes of understanding informed consent, the principle of respect for people is dominant and comprises two concepts: Individuals are to be treated as autonomous agents, and those individuals with less autonomy are entitled to protection. The latter concept is especially relevant in interventions and research involving children, though it is somewhat fluid in its definition because the autonomy of pediatric patients increases as they approach adulthood.

The statement in the Nuremberg Code that "the voluntary consent of human subjects is absolutely essential" has been interpreted as a legal capacity, a power of free choice based on knowledge and comprehension. But consent, which was once seen as a single event, has come to be understood as more of a process. The dominant theoretical framework for morally valid informed consent requires that four criteria be met: disclosure, understanding, voluntariness, and competence. Briefly, the information that must be disclosed includes (a) facts (such as risks, benefits and alternatives) that patients and providers believe relevant to the decision, (b) the recommendation of the professional, and (c) the purpose, nature, and limitations of consent. Understanding goes beyond disclosure because, while the elements disclosed can be objectively stated, true understanding involves many variables and it is more difficult to

assess. Establishing and documenting understanding remains a great challenge because information that has been disclosed but not understood contributes little to the ideal paradigm of informed consent. Voluntariness is another complex notion susceptible to misinterpretation, which means at a minimum that a decision has been made without constraints of coercion or manipulation. Finally, competence, which is conventionally understood as the ability to perform a task, has also become a complex concept whose definitions derive from law, psychiatry, and philosophy. The basis for a person's competence to make a particular decision relates to that person's ability to understand and think about the available choices and to use that understanding to make a decision.

Conceiving of informed consent in terms of the four elements of disclosure, understanding, voluntariness, and competence is useful when considering adults, but informed consent in pediatrics is complicated by the fact that three parties are involved (parent, child, and clinician/investigator) and the fact that the subject of research or treatment is the child. In pediatrics, autonomy does not take precedence. Instead the governing concepts are in "best interest of the child" and "avoidance of harm." The best interest notion is clearer in a purely clinical setting than in a research setting, where interventions are generally designed to contribute to general knowledge. Despite the difficulty of approximating truly informed consent in the setting of pediatrics and especially pediatric research, the obligation to advance pediatric medicine lends urgency to efforts to offer the closest possible approximation to informed consent out of respect for children as people.

In pediatrics, informed consent is better thought of as a combination of parental permission and, where appropriate, the more complex concept of the assent of the child. Many adolescents and some younger children possess the elements of competence. This is especially true perhaps of those who are exposed to long-term clinical trials and to the environment of a children's hospital for long periods of time. Younger children may not be developmentally capable of comprehending complex treatment regiments, but they do have some level of understanding that increases with age and experience. The notion of "assent," which complements the notion of "consent," must take into account these dynamic elements. Together, consent, permission giving, and assent constitute a set of rich ideas directed at preserving human dignity in the midst of vulnerability.

INHERITANCE

Assets accumulated over the life course that remain at death constitute a bulk estate, and the receipt of such a bulk estate is usually defined as an inheritance. Bulk estates are a major mechanism by which wealth is transferred. Because the distribution of wealth itself is highly skewed, so are bequests from estates. The greater the household wealth, the higher the likelihood of having received a bequest. At death, most individuals have little or nothing to bequeath beyond personal belongings and items of sentimental value. More broadly defined, inheritance is more than the transfer of bulk estates; it also refers to the total impact of initial social class placement at birth on future life outcomes. Inter vivos transfers or gifts are resources that are distributed among the living, typically from parents to children. Children of privileged classes are commonly the beneficiaries of a continuous flow of economic transfers that less privileged parents are unable to provide. These transfers are more important for a larger

proportion of the population than the transfers of bulk estates. Socioeconomic position substantially affects quality of life, and disparities in both are often transferred to future generations.

Patterns of inheritance are complex, and vary among societies as well as within a society. Inheritance patterns also vary with lineage systems and residence rules. Some inheritances are accidental; many are intentional. One important form of inheritance is the intergenerational transfer of bulk estates, the specific numbers and sizes of which are unknown. However, it is known that both the distribution and value of bequests are highly skewed, thus contributing to differential future life outcomes and economic advantages. In the following sections these issues are addressed.

Inheritance as the Intergenerational Transfer of Bulk Estates

The rules of inheritance have changed as other larger social, economic, and political structures have changed. What is transferred, to whom, how, and the amounts transferred have also varied historically.

Evolution of Inheritance From Hunter-Gatherers to the Present

Hunter-gatherer societies produced little or no surplus, and equal access to the simple productive technology and the environment resulted in egalitarian subsistence production. Because the accumulation of goods and property was difficult and not necessary, there was nothing to bequeath. With simple technologies that produced nothing to inherit, social stratification in the modern sense was largely absent in such societies.

Horticultural and Agrarian Societies

The first consequential form of inheritance occurred with the emergence of private property and the small-scale cultivation of gardens in horticultural societies. Despite intensive cultivation, small garden plots and simple tools limited food production but did permit small surpluses that were extracted from the less powerful producers by the more powerful, who claimed ownership of the land. This expropriation of surplus both reflected and resulted in increases in economic and political power, which were transmitted along kinship lines through mechanisms of inheritance. From these first systems of inheritance of status and power sprung an early form of social stratification.

With the advent of plows and the more complex technology for cultivation characteristic of agrarian societies, a larger food surplus was possible. Because children were considered economic assets due to their crucial roles in production, birth rates were relatively high. Landowner bequest of property was a significant mechanism for intergenerational transmission of privilege in agrarian societies. Property was typically passed to children of the deceased male, and his surviving wife received a maintenance income for the remainder of her life. Small family farms and businesses were often left to the eldest son, which lessened the problem of dissipating assets by spreading them too thinly among the usually large number of children. By keeping substantial inheritances in the hands of a few, social class inequality was reinforced.

Industrial and Post-Industrial Societies

The Industrial Revolution introduced technology that increased the quantity and rate of production. More efficient modes of production led to greater surplus production and, hence, the potential for greater accumulations over the lives of the producers. This brought more formal rules and practices governing the transfer of inherited properties and goods, and bequests were commonly written in wills and testaments. These rules were more complex than those of less advanced societies, and reflected an evolution of inheritance patterns that mirrored larger societal changes. Further, because the new modes of production involved an increasing use of machinery and less reliance on labor-intensive forms of production, the Industrial Age saw a distinct decline in the number of family farms. Fewer farms and small businesses remained to be inherited, so inheritances came to consist of money and other fungible goods produced by the liquidation of the decedent's property.

As modes of production changed, there were concomitant changes in what was inherited as well as in who was to inherit. Bequests came to be distributed among multiple heirs, but the equal dispersion of funds was easier because money is easier

to divide equally than farms or other forms of business property. Inheritances were also distributed to fewer offspring, which reflected the decline in birth rates compared to preindustrial societies. Other less fungible transfers, such as education, became a means through which opportunity and advantage were passed between generations. Educational institutions make admission decisions based on both merit and nonmerit attributes, and those who came to possess educational credentials, by whatever means, also came to have occupational and income advantages.

The advanced mode of production of modern industrial and postindustrial societies has led to vast surpluses and substantial economic inequalities. Although there is more for the privileged to inherit, social stratification has become less rigid.

Timing and Recipients of Inheritance

The timing of inheritance has also changed with societal evolution. Given the greater life spans found in industrial societies compared to those in less developed societies, individuals may live well into their 80s or 90s, with their children already middle aged before their parents die. The longer life cycle has meant a longer time from birth until receipt of inheritance. This, along with attempts to evade the taxation of bequests, has led to an increase in inter vivos transfers.

In industrial and postindustrial societies, by the time an individual dies, heirs are usually already established in their own careers, so an inheritance may not play the same role in the recipient's life as it would have in earlier societies. Given this, some individuals make bequests to their grandchildren, who might benefit more substantially than their adult children. Such generation-skipping trusts have become commonplace and typically occur when the deceased are confident that their own children are financially secure.

Other changes in family structure have complicated patterns of inheritance. As divorce rates rose in industrial societies during the 1960s and up to the early 1980s, the structure of the family changed. Different family structures led to more complex patterns of inheritance, as individuals divided estates among birth family members and stepfamily members.

Taxation of Inheritance

Inheriting an estate means accumulating assets other than wages and salaries. While vast wealth disparity is well documented in industrial society, there is a lack of systematic and comparable data on wealth transfers. In many societies, including the United States, only a very small proportion of estates are taxed. Estate taxes are essentially excise taxes on the privilege of transferring property upon death. The rate varies among societies but, typically, the larger the decedent's estate, the greater the tax liability. In addition to estate taxes, societies can have inheritance taxes, which are taxes levied on the privilege of receiving property from the deceased. Such taxes can vary considerably by state, as well as by the amount of property transferred, and the relationship of the heir to the decedent.

Typically, only very large estates are taxed; thus there is no systematic or complete accounting of the transfer of wealth across generations. Data for the United States indicate that wealthy parents pass on about half of the advantages associated with their wealth to their children.

Inheritance as Inter Vivos Transfers

Inheritance remains an important basis of intergenerational inequality because inheritance is more than the intergenerational transfer of bulk estates. Inheritance also refers to the total impact of initial social class placement at birth on future life outcomes. Children of privileged classes are commonly the beneficiaries of substantial and continuous flows of economic transfers. Parents seek to advance the futures of their children for a variety of reasons that include securing their own futures in the event that they become unable to take care of themselves or realizing vicarious prestige through the success of their children. With increasing overall life expectancy, grandparents have also become more actively involved in advancing the futures of grandchildren, both through inter vivos transfers and the provision of estates (including the use of generation-skipping trusts), thereby extending the potential for the transmission of privilege across multiple generations.

Advantages of Inheritance

There are several cumulative, nonmerit advantages of inheritance. Even minor initial advantages can

accumulate over the life course, reinforcing or extending existing inequalities across generations. These advantages are passed between generations in varying degrees.

The first of these advantages is that children inherit a standard of living and a quality of life from their parents. This includes basic necessities such as food, clothing, and shelter, but also extends to perquisites, amenities, and other sources of material well-being beyond subsistence. For the most privileged, this form of economic inheritance includes entertainment of various forms, toys, travel, vacations, enrichment camps, and private lessons, for example.

Second, from their parents children inherit cultural capital, or the knowledge and information needed to function as a member in good standing in society. This knowledge includes the ways of life of a group: lifestyles, consumption patterns, norms, values, beliefs, customs, and traditions. It includes, but is not limited to, etiquette, patterns of speech, demeanor, and comportment that are required for acceptance in higher social circles. This is a powerful but subtle means of transmitting social standards and social standing from one generation to the next.

The third of these advantages is that children inherit social capital from their parents. Social capital refers to social connections, and these networks provide access to power, information, and other resources. Children initially inherit a network of social relations from their parents. These connections can be important mechanisms of formal and informal social placement and advancement.

Fourth, the advantages of inheritance can be transmitted through inter vivos transfers. The parental infusion of capital to children can provide substantial advantages at critical junctures in the life course, such as going to college, getting married, buying a first home, and starting a business. These transfers are often substantial, and evidence suggests they are of equal or greater value than lump sum bequests.

These transfers are called transformative assets because of their capacity to lift a family beyond its own ability to generate assets. With the rise of corporations and the concomitant decline of family farms and businesses, inheritance increasingly takes on more fungible or liquid forms. Increasingly, a primary form of inter vivos transfer is payment for higher education, which in turn has the capacity to increase an individual's prospects for subsequent social mobility. In essence, these transfers represent parental investments in their children's future and future life chances.

Fifth, the advantages of inheritance may take the form of parental rescue or insulation from downward mobility. If society operated on strictly merit principles, then individuals who exhibit little merit would become downwardly mobile; however, parents often provide financial and other forms of support and intervention that prevent this. Adult children may seek parental assistance because of illness or injury, unemployment, divorce, or other setbacks. Parents may also provide intervention for adult children's personal problems in the form of legal assistance, counseling, or substance abuse rehabilitation. The full extent of these various forms of parental rescue is unknown, but the increasing number of so-called "boomerang" children or adult children who return to live at home with parents, often between jobs, marriages, or other setbacks offers indirect evidence that this form of inter vivos transfer is fairly common.

Sixth, in addition to financial assets, children inherit prospects for quality of health and life expectancy. There is overwhelming evidence of a wealth-health gradient in which the risks for illness, injury, and death are lower for higher socioeconomic groups. This pattern has multiple causes, beginning with prenatal care and extending through old age. Individuals from wealthier families have better diets, health care screening and prevention, intervention, and access to high quality health care. Childhood protection from exposure to disease and health risks can influence later quality of health and earning capacity, and are therefore forms of parental inheritance.

Finally, children may be the beneficiaries of bequests from parental estates. While only about 20% of U.S. households report receiving bequests, as familial wealth increases, the chances of receiving such bequests also increase. When bequests of bulk estates are made, they often involve substantial amounts, and are a major mechanism though which economic inequality is reproduced across generations.

Disadvantages of Inheritance

The most obvious disadvantage associated with inheritance is the familial conflict that results from

disinheritance or the contesting of a will. Furthermore, in societies that particularly value individual achievement and meritocracy, recipients of inheritance may experience a form of cognitive dissonance in which they feel guilty or unworthy of the privileges and advantages bestowed through inheritance. Inheritance or the prospect of inheritance can serve as a disincentive for individual achievement, bring unwelcome public scrutiny, jeopardize privacy, or even threaten one's security. On balance, however, the advantages of inheritance appear to outweigh the potential disadvantages.

Instrumental Grieving: Gender Differences

It is suggested that different socialization experiences or biological differences cause men and women to exhibit distinct patterns in the way they experience, express, and adapt to grief. It is further suggested that the male role inhibits grieving because it emphasizes the regulation of emotional expression while diminishing the supposed need to seek support from others. Women, on the other hand, are more receptive to accepting help and more willing to express emotions, both of which are seen as facilitating the grief process. And Alan Wolfelt posits that men's grief is naturally more complicated because they cannot express emotion or seek help. Despite such claims, the research in the field of thanatology clearly challenges these perceptions.

Research Perspectives

Therapists' Views

In one study conducted during the 1990s, the analysts evaluated the views of certified grief counselors and therapists as these pertain to gender differences in grief. Their sample did hold to the belief that men and women expressed grief differently. To wit, men were perceived as less likely to express strong emotions and more likely to use diversions such as work, play, sex, or alcohol as avoidance strategies in lieu of grieving. Therapists reported that men were more likely to respond cognitively, and to use anger as a primary mode of emotional expression. Women were perceived as more likely to express grief affectively and to seek support. The counselors in the sample also found differences in the expectations and support men and women experienced from others. Others expected men to get over their loss more quickly and be able to function more effectively. Women were seen as needing and receiving more emotional support, but others also viewed women as more of a social risk who would be more likely to break down in normal social situations. The result was that these therapists reported their women clients received more comfort-oriented support but fewer

opportunities for normal social activity than their male counterparts.

Despite these differences in the expression of grief and the support level they are likely to receive, the counselors in this project did not report differences in outcomes. In fact, the therapists surveyed saw different risks for each gender. In their view, men were more at risk for certain types of complicated grief reactions, while women were more prone to depression or chronic mourning.

Gender-Based Studies of Grief

The perspective of therapists, explicitly or implicitly, is grounded in much of the research that shows a difference in the ways men and women grieve. Summarizing the extant literature that addresses this issue, during the late 1990s Terry Martin and Kenneth J. Doka note the following:

- Research on widows and widowers has shown that widows and widowers face different problems in grief. For example, many widows report financial distress and note the emotional support provided by their spouse. Widowers were more likely to report disruptions of their familial and social networks. Widows were more likely to seek emotional support, while widowers found solace in exercise, work, religion, creative expressions, or more destructively in alcohol.
- Many of these same results are evident in the loss of a child. Mothers reported more emotional distress than fathers. Strategies in dealing with the loss differed by gender. Women tended to use more support-seeking and emotion-focused strategies, while men were more likely to intellectualize their grief and use more problem-focused strategies to adapt to the loss.
- Studies of the loss of a parent also showed that middle-age sons were less likely than daughters to experience a high intensity of grief and somatic manifestations, and more likely to utilize cognitive and active approaches in adapting to loss.
- Differences between genders seem less apparent in older cohorts. This may reflect the idea that individuals become more androgynous as they age.
- Differences in gender are also affected by other variables, such as social class, cohort, and cultural differences.
- The research on differences in outcome is quite mixed. Some studies have shown men to have better outcomes, others show women to do better, while still other studies show no significant difference or mixed results in outcome (i.e., men do better on some measures, women on other measures).

This research does have implications for counselors. Whether one evaluates this difference as resulting from gender orientation or as patterns influenced by gender, the results suggest that different responses to loss can affect relationships within the family when a loss to that family is experienced. Assisting individuals to identify and discuss the ways they deal with loss and helping families to address how these differences affect each other's grief are important outcomes.

Patterns of Grief

It is suggested that we should look beyond gender to understand different pattern or styles of grief. Martin and Doka propose that these patterns are related to gender but are not determined by them. They suggest that gender, culture, and initial temperament interact to produce a dominant pattern of grief. They view these patterns of grief as a continuum. Martin and Doka further acknowledge that such patterns are likely to change throughout an individual's development, often moving more toward the center of the continuum as an individual moves to late adulthood. Based upon the underlying concept of emotion regulation, three basic patterns of grief are presented.

Intuitive

Intuitive grievers experience, express, and adapt to grief on a very affective level. Intuitive grievers are likely to report the experience of grief as waves of affect or feeling. They are likely to strongly express these emotions as they grieve—shouting, crying, or displaying emotion in other ways. Intuitive grievers are also likely to be helped in ways that allow them to ventilate their emotions. Self-help and support groups, counseling, and expressive opportunities that allow them to ventilate feelings are likely to be a useful strategy.

Instrumental

Instrumental grievers are more likely to experience, express, and adapt to grief in more active and cognitive ways. Instrumental grievers will tend to experience grief as thoughts, for example, a flooding of memories or in physical or behavioral manifestations. They are likely to express grief in similar ways—doing something related to the loss, exercising, or talking about the loss. For example, in one case, a man whose daughter died in a car crash found great solace in repairing the fence his daughter had wrecked. "It was," he shared later, "the only part of the accident I could fix." Instrumental grievers are helped by strategies such as bibliotherapy or other interventions that make use of cognitive and active approaches.

Dissonant

Dissonant grievers are those who experience grief in one pattern but are inhibited in finding ways to express or adapt to grief that are compatible with their experience of grief. For example, a man might experience grief intuitively but feel constrained from expressing or adapting to grief in that way because he perceives it as inimical to his male role. Similarly, a woman might also experience grief in a more intuitive way but believe she has to repress that feeling in order to protect her family. Counseling with dissonant grievers involves helping to identify their inherent pattern, recognizing the barriers to effective expression and adaptation, and developing suitable interventive techniques. In Western culture, many males are likely to be found on the instrumental end of this continuum, while women are more likely to be found on the intuitive end. However, although gender influences the pattern of grief, that pattern is not determined by gender. It is also noteworthy that many individuals in the center of the continuum may show more blended patterns, utilizing a range of emotion and behavioral and cognitive strategies to adapt to loss.

Implications

The concept of grieving styles and patterns is part of a general trend in the field of grief studies that emphasizes the individual pathways of grief rather than seeing the process as a universal and predictable series of stages. This has implications for grief counseling and grief support. First, grief counselors should carefully assess the ways that individual clients have tended to experience, express, and adapt to grief. This careful assessment is the first step in designing interventions suited to their grieving styles that build on their historic strengths.

There has been discussion of the value of more androgynous approaches—that is, designing interventions that seek to move people toward more blended styles. For example, Henk Schut, a researcher in the Netherlands, found in one study that women seemed to benefit more from cognitive-based therapies, while men found more value in affectively based approaches. However, as Martin and Doka noted, Schut's research was based on gender. Therefore, there was no knowledge of grieving styles prior to their participation in the research. Moreover, Martin and Doka emphasized that crisis is often a poor time to teach new modes of adaptation and that except in situations where previous adaptations have been unsuccessful, people do well to use their historic strengths. Nonetheless, these discussions reaffirm both the importance of assessment as well as the need to intentionally and individually design interventions that are sensitive to an individual's style or pattern of grief.

Second, organizations such as hospices, hospitals, grief centers, or funeral homes that offer grief support need to recognize that multiple approaches are likely to meet the needs of a wider range of clients than one approach. Counseling and support groups, for example, often appeal to intuitive and more dissonant grievers. Educational offerings on grief, a grief lending library, access to web-based resources, and even memorials and other types of ritual events may widen the organization's ability to support people who grieve in more instrumental ways.

Culture and Gender

Any analytical discussion of gender differences in grief or evaluation of patterns of grief that are influenced by gender should consider cultural differences. Culture influences grief in a number of ways. First, each culture has norms that govern the ways grief is appropriately expressed. In some cultures these norms can differ between genders. In one study conducted during the 1970s, Paul Rosenblatt

and his associates found that in the 60 societies surveyed, 32 had no differences in the expectation of crying between men and women. In the remaining 28 societies, women were allowed more emotional expressiveness. Also, each culture defines relationships in different ways, influencing the level of attachment. These, too, may differ by gender.

Conclusion

The concept of grieving styles or patterns reminds researchers, academicians, and clinicians not to place too much emphasis on gender alone. Gender and socialization to gender roles in any given society certainly influence grieving styles, but gender alone does not determine the ways that people grieve. The adoption of any given grieving style is influenced by other variables, including culture, temperament, as well as socialization and developmental experiences.

Isolation

Isolation refers to the state of separation. It is an external, objective condition that can be measured and to some extent controlled. Dying is an isolating experience. In its most general meaning, isolation is separation or the absence of relatedness. Isolation is essential to understanding the nature of dying, for it is in dying that our relatedness to a surrounding world is undone. Because both isolation and dying causes one to withdraw from communication, the isolation of dying is difficult to understand. To illuminate its meaning, the relationship of isolation to dying is evaluated within the context of the following issues: identification of the isolative impact of dying, how such isolation is experienced, and how further understanding of the isolation of dying may be achieved.

Isolation of Dying

Isolation of dying refers to various conditions, the first of which is social isolation. Declining health, a decreasing social network, the loss of social roles, and loss of partner and family members often precede dying. Social isolation is exacerbated when one's family is distant and hospitals and nursing homes have restricted visiting hours. The second condition is emotional isolation. Overwhelmed by confused feelings pertaining to impending death, people experience difficulty expressing their feelings. Emotional isolation is exacerbated when inaccurate communication is offered by caregivers and loved ones who experience difficulty in confronting the dying. Third, the isolation of dying refers to existential isolation or being alone in facing death. Existential isolation may be exacerbated by dissociation from religious beliefs and by a lack of spiritual care. Depending on the type and duration of the illness, as well as on personal and health care circumstances, some ways of dying tend to be more isolating than others. However, dying not only isolates one from one's self and others but from life as well. Indeed, dying is a state of total isolation, making existential isolation unique to the isolation of dying.

Loneliness of Dying

Subjectively perceived and internally evaluated, isolation becomes an experience. Loneliness represents a negative aspect of isolation, the distress of being separated. When death is experienced in a negative way, the existential isolation of dying is

portrayed as existential loneliness. Existential loneliness refers to the terrifying experience of isolation that results from the awareness that one is a separate individual being. This fundamental separateness makes the experience of existential isolation an empty, timeless, and toneless quality. As dying eliminates all our relationships, existential loneliness of dying is the awareness of the absence of any other awareness, perception, or feeling.

Explication of the experience of existential loneliness of dying in terms of nonrelatedness makes this experience enigmatic. After all, it remains unclear how the absence of any relatedness may lead to an experience at all. The existential loneliness literature purports to solve this riddle mainly by means of a phenomenological theory of consciousness. Phenomenology claims that consciousness exists only by virtue of the fact that a subject is necessarily directed toward an object. Without this relationship, consciousness is nothing. In the case of dying, consciousness can no longer be directed to an object. As a consequence, consciousness becomes aware of its own nothingness. It is suggested that it is precisely this nothingness that is represented in the experience of existential loneliness and, together with that, in loneliness of dying. However, it is difficult to see how nothingness that results from the absence of relatedness can be explicated in positive terms. Therefore, it is claimed by some analysts that the existential loneliness of dying cannot be explicated other than by its own nothingness.

Solitude of Dying

Because isolation of dying cannot be further understood by a direct exploration of the experience itself, two other strategies are proposed for a more extended understanding of the isolation of dying. First, isolation of dying can be understood by recognizing one's own solitary nature. To do so, one has to withdraw into solitude—the positive experience of isolation. Through introspection and voluntary separation from others we confront our own finiteness. By doing so, we become aware that all the projects and plans we make are structured by our finitude. The awareness of finitude is thus a positive confirmation of life for it makes it possible to us to live our lives according to what we are: finite human beings. Most people, however, turn away from both solitude and a full awareness of being mortal. Because this avoidance may be explained as a self-protecting strategy, the claim that increased awareness of one's own finitude leads to a better understanding of isolation of dying seems to be without merit.

Second, the isolation of dying can be understood by exploring the philosophical presuppositions that underlie the conceptualization of existential isolation. As these presuppositions incorporate various anthropological claims concerning human's lonely nature, their explication brings to light subtle but important differences in understanding the experience of isolation. Elaboration of these differences in the context of dying illuminates which circumstances and interventions cause deterioration or amelioration of the experienced isolation. Questions as to what these circumstances and interventions are have yet to be the object of further empirical research.

Jewish Beliefs and Traditions

For the Jew, beliefs about life and death are firmly rooted in the world of the living. Judaism has no dogma concerning what happens to a person after death (such as heaven and hell). Rather, a Jew is taught to live life to its fullest and perform deeds of loving kindness for as many people as possible. Rewards and punishments for behavior occur in this world, but also affect our final status in the world to come. Life is so precious that saving a life is the highest ethic and demands the breaking of all other *Mitzvot* (commandments) in order to do so. Further, death is regarded as a natural part of being human. The story of Adam and Eve explains the introduction of death to the world. Adam and Eve were dismissed from the Garden of Eden to avoid becoming like the angels, living eternally yet childless by continually eating from the tree of life. Instead, human beings were meant to leave progeny and live for a limited time. Judaism, like other religions, focuses on coping with the reality that although human beings may wish to live forever, the body is mortal. A dominating theme in Judaism is that one continues to live on after death in the memories of one's children and grandchildren, which is reinforced with rituals and memorialization. Judaism must help its adherents recover from the trauma of death to return to the world of living despite the absence of a loved one. To do this, the mores of Jewish law cover three areas: (1) care and disposition of the remains, (2) acclimation of the mourner to a new life, and (3) keeping the deceased's memory alive. Within a Jewish religious and cultural framework, the mourner can depend on these traditions to treat the deceased with dignity, help ease the pain of bereavement, and memorialize loved ones. Rich in symbolism, ritual, and spirituality, the phases of Jewish mourning carefully bring the bereaved through the anguish of grief using the structure of ancient traditions and the support of the community.

Care and Disposition of the Remains

Jewish law defines the mourner as a parent, spouse, child, sibling, or half sibling. While extended family and friends certainly grieve, only the mourner is required to observe the following laws. Upon learning of a death, the mourner enters a period of *ahneenoot* (mourning, literally, being thrown into a world of chaos). All daily rituals are suspended and every effort is directed toward preparing for the funeral. The general rule is that burial should occur within 24 hours of death.

Jews consider the body, the sacred vessel of the soul, as created in the image of God; therefore, it is to be cared for with the utmost respect. The body is not to be left alone from death until burial. It is to be watched over by a *shomer* (guard), lest rodents or body snatchers molest it. Specially trained members of the community (the *Chevra Kadisha,* or Jewish Sacred Society) prepare the body by washing it with a solution of water, vinegar, and eggs. During this solemn ceremony known as *t'hara* (cleansing), the members of the

Chevra Kadisha recite prescribed benedictions and psalms and do not engage in trivial conversation.

The body is dressed in *tachrichim,* which are hand-sewn shrouds made of linen or muslin that are without pockets. These garments indicate that all people are identical, regardless of status, and that there is no need to carry anything to the next world. This tradition arose because at one time in Jewish history people would desert the body of their loved one when they could not afford the high cost of new garments and fancy caskets. Thus, in the 1st century C.E., Rabbi Gamliel made an official declaration that everyone would be buried in identical clothing and similar plain caskets.

There is no public viewing of the body. Because burial occurs quickly, the body is not embalmed. Tradition dictates that people are to be buried with their body intact; thus, an autopsy is not allowed except when required by law. The body is then placed in an *aron* (a plain wooden casket, see photo). No metal is to be used because metal brings to mind implements of war, adornment of a casket can be expensive, and metal deteriorates at a slower rate than the body itself. The use of flowers to mask the smell of a decaying body arose in cultures that delay the funeral for several days. Flowers are now used as a memorial and expression of condolence, but are not seen at a Jewish funeral. Instead, family and friends donate *tzedakah* (charity) to a fund or cause that was important to the deceased.

Funeral Service and Burial

The *l'vaya* (funeral service) consists of reading Psalm 23 and other psalms, a eulogy consisting of *hesped* (praise of the deceased) and *b'chi* (an expression of the family's grief). The service concludes with the reciting of the *El Malay Rachamin* (God Full of Mercy), a prayer asking God to bring the deceased person back under God's sheltering wings.

Kriah (a tear) is made in the mourner's clothing or on a ribbon attached to the clothing. This external symbol of inner grief signifies that a loved one has been torn from one's life. Kriah is performed on the left side for a parent and on the right for all other relationships. This rending of the mourner's garment gives an appropriate indication of bereavement without marking the body, which was an ancient pagan practice.

At the cemetery, the pallbearers make several stops on the way to the grave to show reluctance to perform this act. The body is then buried in the earth. Cremation is not a traditional form of disposing of the body and, in fact, is against Jewish law. In Israel today, due to the desert climate and scarcity of wood, caskets are not often used, and it

Plain pine casket—no metal used

is not unusual to bury the deceased directly in the ground. In an Orthodox burial, crockery is sometimes placed over the orifices so as to block the soul's return to the body. An observant Jew may be buried in a coffin with a bottom that slides out so that the body touches the earth. Some religious Jews make prior arrangements to be buried in Israel to be closer to the place of Judgment when the Messiah comes. For a burial outside of Israel, Israeli dirt is added to the coffin to provide a connection to the Holy Land and to be a guide at the time of resurrection (one of Judaism's many beliefs about life after death). The grave is filled in completely by those present to reinforce the reality of the death.

The service at the cemetery concludes with the recitation of the *Kaddish* prayer. The mourners leave the gravesite through a double line of friends and family as the following Hebrew words are spoken: *Ha-makom y'nachem etchem b'toch aveley Zion v'Yerushalyim* (May you be comforted among the mourners of Zion and Israel).

Acclimation to Life Without the Deceased

With the death of a loved one, chaos ensues. However, the continuation of life and living is *sine qua non* in Jewish thought. To bring order back to life, Judaism dictates *aveelut* (withdrawal from the community) for a 7-day period. After the funeral, the next weeklong phase of the mourner's life begins: *shiva,* meaning seven. The day of burial is the first day and the last day one needs observe for only 1 hour.

Upon returning home after the funeral, the mourner and everyone who was at the cemetery washes their hands ritually before entering, a custom that symbolically washes away the "evil spirits" and ritual impurities associated with death and the cemetery. Immediately, the mourners are commanded to partake of a *se-udat havra'ah,* a meal of recuperation or consolation. They begin by eating a hard-boiled egg, symbolic of ongoing life. A dairy meal is served because dairy is easy on the digestive system and this is often the first meal the mourners have eaten since the death. The community provides the se-udat havra'ah, a tradition that ensures that the mourner is not alone and reminds the bereaved that he or she must continue with life. During the shiva period, mourners are directed to sit upon low stools and remove leather shoes to reflect the humble feeling that they are experiencing. A tall candle that burns for 7 days is lit.

The first 3 days of shiva are the most intense and are the minimum number of days of mourning. Those who visit the bereaved during this period are instructed not to offer words of comfort, but only to sit with the mourners and wait for

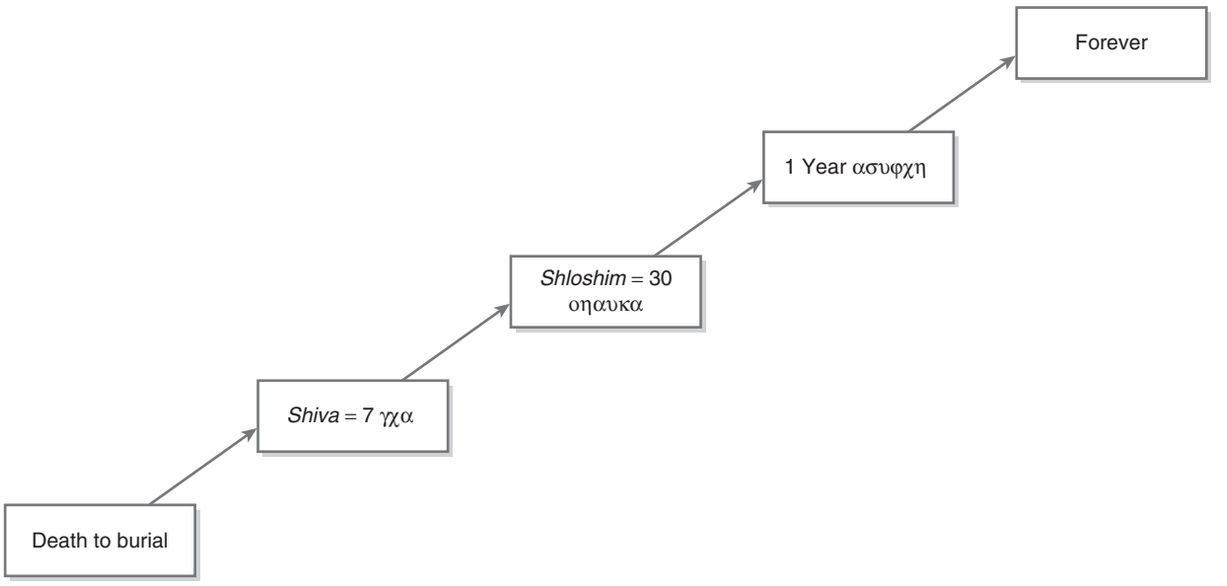

Figure 1 Timeline for Jewish Mourning

them to speak. Shiva is for one purpose only: to help the mourners explore the emotional catalog of regret, relief, guilt, anger, shame, self-pity, and remorse. During the shiva period, the mourners slowly move from withdrawal to socialization. In observant homes, a *minyan* (prayer quorum of 10 adults) will pray together 3 times a day to enable the bereaved to say requisite prayers without having to leave the house. In less observant homes the minyan usually meets only in the evening. These gatherings also provide a community of support, which the mourner can count on without having to ask. If one is a doctor and needed in the community, or a day laborer who is the sole provider for the family and it is a financial necessity, the mourner may return to work but must take time during the day to grieve.

During shiva mourners are exempt from all requirements of daily life and are restricted from its pleasures as well. They are not to bathe or shower for pleasure (they can if required due to body odor). They are not to cut their hair, shave, or put on freshly laundered clothes, for they should concentrate on their loss and not on their appearance. Mourners are not to engage in sexual activity, but can engage in other forms of intimacy. Mourners are not to study Torah, for this is a source of pleasure for many. Mirrors in the home are covered to prevent mourners from gazing on themselves and engaging in vanity.

Shloshim (literally, 30 days) is the second, less intense period of mourning. The counting begins from the date of death. During shloshim, mourners are not to attend weddings, bar or bat mitzvahs, or other joyous events with music. Mourners are not to get married during this period, nor are greetings to be extended to them, but they can extend greetings to others. Instead of praying at home, mourners are to join the minyan 3 times a day in the synagogue. When mourning for parents, one prays in the synagogue for 11 months and does not attend joyous events or listen to music for *yud-bet hodesh,* a 12-month period from the date of death. During this year one does not shave or cut one's hair, unless someone remarks about it being unkempt.

Keeping the Deceased's Memory Alive

In response to fears that loved ones will be forgotten, Judaism created *Yiskor,* a structure of remembrance. Yiskor is observed 4 times during the year: on Yom Kippur (the Day of Atonement) and the three festival holidays (Passover, *Shavuot,* the Feast of Weeks or Pentecost, and *Sukkot,* the Harvest Festival). The deceased is memorialized a fifth time during the year on the *yahrzeit,* the anniversary of the day of death. These traditions acknowledge that mourning goes on forever and the deceased are never really forgotten. On these five occasions the Kaddish prayer is recited by the children of the deceased and other mourners as previously defined. Written in ancient Aramaic, the Kaddish does not mention death at all but, rather, praises and thanks God for having lent our loved one to us. Because it is not unusual for the bereaved to have feelings of guilt, reciting Kaddish also gives people a sense that they can still affect the deceased in the world to come. By reciting Kaddish, the mourner tells God that the deceased is remembered for all of their good and worthy deeds. The observance of yiskor and yahrzeit is done in a minyan so that the bereaved realize that he or she is not alone in mourning. In addition, a contribution to charity is usually given in memory of the deceased on the yahrzeit.

As part of the system of remembrance, after a period of time the family and the community return to the cemetery to dedicate a *matzevah* (tombstone). In Israel the custom is to do this at the end of a month. In other countries it is usually between 11 and 12 months after the death (timing can vary depending on climate). Written on the matzevah is the person's name in both their native language and in Hebrew and the dates of birth and death. Sometimes an epitaph is included. Upon visiting the cemetery, rather than flowers, Jews leave a stone on the matzevah as a permanent marker that they were there. During the Ten Days of Repentance, between Rosh Hashanah and Yom Kippur, it is traditional to visit the cemetery and say a prayer at the graveside. It is not unusual for an additional memorial in the name of the deceased to be dedicated in a public place, a synagogue, or a community building, or for a philanthropic fund to be established in their memory. Another way of memorializing the deceased is to name a child after the person, not only to keep their memory alive, but also in hopes of passing on their best qualities to the next generation. Jews often acknowledge the death of a person when mentioning their name by

saying *alav ha-shalom* (may peace be upon him or her) or *zicharono livracha* (may his or her memory be for a blessing).

At times, life and death clash, such as when a death occurs within days of a wedding or immediately thereafter. In both cases, because living is the highest ethic for the Jew, life prevails and the celebration continues. The 7 days of marital bliss are observed first, then one observes shiva thereafter. Should other complications or questions arise, such as a delay in news of the death reaching the mourner, a rabbi should be consulted to determine the best way to observe the mourning period.

Changes to Traditions as Jews Encounter Other Cultures and Modernity

Wherever Jews have lived they have been influenced by the practices of the secular culture. For instance, Jews from Russia will gather before the open casket and wail and bawl openly. At times it almost seems that they want to throw themselves on the coffin as it is lowered into the ground. This is not traditional among American Jews. As Jews were assimilated, some of the more liberal adopted the customs of burying the deceased in dress clothes and metal caskets. As families have dispersed throughout the country or world, the burial may be delayed beyond the 24-hour period so essential mourners can be present. Also, with the rise in popularity of cremation, some Jews are choosing this less expensive manner of disposing of the body. Although the aforementioned traditions are the standard and guide, various modifications are observed depending on the mourner's culture and degree of Jewish observance.

JIHAD

Jihad is an Arabic word used principally by Muslims to connote spiritual struggle directed either to the internal cleansing of one's soul or toward external forces deemed to be a threat to the harmonizing of humankind with God's will. It is the latter interpretation that has likely led some non-Muslims to simplistically define jihad as "holy war," however for many (if not most) Muslims jihad is a complex idea not easily reduced to a simple recipe for action. For example, an internal struggle to purify one's soul also might call for externally directed actions in service to Allah's will, but such actions need not be aggressive, any more than the efforts of other proselytizing religions are necessarily aggressive. Nevertheless, scholars continue to search for consensus as to the true meaning of jihad in a debate that has been ongoing in the Muslim world for centuries and highlighted and intensified by recent terrorist events. Because it is essentially spiritual, jihad may be inextricably linked to both individual and collective conceptions of attitudes toward death and, as is well known, often leads to the deaths of *shaheed* (martyrs) and nonbelievers alike. There is disagreement among Muslims as to whether the Quran unequivocally forbids suicide or actually calls for martyrdom and/or the destruction of nonbelievers as the ultimate expression of Muslim faith. These debates aside, multiple social scientific explanations and analyses of jihad have been offered focusing on the various religious, economic, political, cultural, social, and psychological aspects of the phenomenon. Although most accounts are multidimensional, all tend to lead toward one or another discipline as a point of departure and may be

categorized accordingly. The categorization that follows is just one of many possibilities, as jihad remains a complex phenomenon.

Economically Centered Explanations

Analyses that focus on economic factors generally view jihad as a reaction to the modernizing and Westernizing influences of global capitalism. That is, jihad is understood as the reaction of a culture that perceives itself to be under threat from the blanketing effects of globalization. Capitalism is described as an economic system that has little regard for local traditions and noneconomic elements of social structure. Benjamin Barber, for example, characterizes jihad as a manifestation of a larger trend toward tribalism, that is, toward efforts to find an identity with a particular social or cultural group that might provide some defense against the destructive and homogenizing effects of global capitalism. Jihad has become the rallying cry for some Muslims who believe their values and traditions are being ground up in capitalism's blind pursuit of profit. Therefore they choose to respond to the juggernaut of global capitalism with an equally forceful and focused pursuit of Islamic traditions, albeit their own particular version of those traditions. Given that individual and collective identity are believed to be threatened with annihilation by this impersonal, secularizing, and foreign created system, killing of the just and the unjust alike is deemed unavoidable.

Politically Centered Explanations

Other efforts to explain and understand violent jihad take politics as the point of departure. The argument is that some Muslims are incensed by Western encroachments on the autonomy of Arab governments, particularly the occupation of Muslim lands by foreign elements. Whether the issue is the presence of U.S. troops in Saudi Arabia or Jews in Jerusalem, the fact that non-Muslims are thought to be defiling Muslim holy sites becomes a justification for violence. Indeed, many analysts have noted that al-Qaeda has repeatedly cited the presence of American forces in lands sacred to Muslims as reason for violent attacks against American targets. Of course, the focus on the political motivations of jihad does not preclude recognition of its economic, religious, and cultural dimensions, for these are often cited as interacting, contributing variables. Nevertheless, for some observers, the locus of power, especially as it relates to the control of land, is seen as the critical force behind the violence. Within this framework, violent jihad is understood to be driven primarily by a desire to restore political and territorial control rather than by the marginalizing effects of global capitalism.

Psychologically Centered Explanations

One popular argument regarding the motives behind *mujahidin* (those engaging in jihad) violence focuses on the vulnerability and naiveté of impressionable young suicide bombers enticed by the promise of heavenly bliss. In fact, inducements may include both the ethereal and the practical—the former including the fulfillment of sexual fantasies, perpetual reverence, and enhanced esteem for one's family, and the latter involving much needed financial support for loved ones left behind. Individuals willing to pay the ultimate price are designated martyrs, and martyrdom is defined as one of society's most valued social roles. Such psychologically centered explanations may apply to rich and poor alike, both the well-educated leaders of the September 11 hijackers and the impoverished teenager from the West Bank.

At the foundation of a psychologically centered argument is a personal frustration felt by some Muslims in the face of current Western dominance. Such arguments recognize the sense of frustration and humiliation that can be engendered by the economic and political imbalance between Muslim and non-Muslim countries, particularly given the past glories of Islamic civilization. When felt strongly, this perceived injustice can lead one to turn one's frustrations on symbols of Western power and influence in order to restore Islam to its rightful place in the world. A more nuanced examination of the psychological dynamics of terrorism, one that predates current concerns, centers on what many social scientists have identified as humankind's quintessential fear of death. Such theories presuppose that the human capacity to contemplate one's own mortality is the driving force behind much human behavior, including a penchant for warfare. These theories take many paths,

but one general line of argument is that we humans project our fear of death onto others whom we then kill as a means of controlling death and overcoming our inherent fear. Indeed, among the many insights of Robert J. Lifton into the connection between death and war is that the definition of an enemy is someone who must die so that we ourselves may overcome death. Thus, it could be argued that all who set out to kill an "enemy" are acting out of motives inherent to the human condition, whether in the name of jihad or of the state.

However, it should be noted that the definition of death in this context is something other than one's physical death. For many, mujahidin take their own life in furthering their cause. The pursuit of spiritual purification may indeed require personal sacrifice in order to bring about a larger collective purification that promises the end of death for all who believe. Psychological arguments notwithstanding, theories of jihad that center on this link between individual and collective struggles to overcome mortality often use religion as the starting point.

Religiously Centered Explanations

Jihad may be viewed as just one of a number of religiously motivated movements that see spiritual purity as a zero-sum-game in which the existence of other religious traditions can be a threat to one's own. Consequently, some adherents may feel compelled to diminish if not destroy those groups perceived as threatening to their own religious worldview. From this perspective, it is the underlying drive for spiritual purity pitted against external forces believed to be bent on compromising or destroying that purity that is responsible for violence. It matters little whether one's target is a doctor who performs abortions or an Arab politician believed to be too friendly with secularism. Such religiously motivated groups and individuals perceive themselves to be locked in a struggle with the forces of evil and are willing to use all necessary means to ensure the ultimate primacy of their religious doctrine and avoid spiritual annihilation for themselves and their coreligionists.

Given its currency in popular culture, a religiously centered explanation that deserves mentioning is one that attributes violent jihad to what some believe to be the inherently violent character of Islam. Support for this argument is said to be found in the historical record, particularly that of Islam's early conquest of the Middle East and its rapid spread to distant parts of Europe and Asia. It is suggested that the current incidence of Muslim terrorist violence is simply a modern manifestation of an innate quality of the religion. Such theorizing, however, seems to be found less frequently within the social sciences and, at best, simply moves the question of violence back to the origins of Islam and, at worst, makes simple work of what some consider to be a complex contemporary phenomenon.

Associating terrorism to the service of spiritual purification with humankind's anxious relationship with death, the sacrifice of self and others in service of a "higher" cause is neither a new phenomenon nor one unique to any particular religion or ideology. Some theorists observe that it has always been the business of warriors to lay their lives on the line. The fact that some willfully target innocents while others do not may open the door for debate over the morality of their actions, but it does not change the reality that historically humans have shown a willingness to sacrifice themselves and others in order to further a cause. To explain this willingness, some theorists have suggested that our species harbors a fear greater than physical death, and that fear, according to the sociologist Ernest Becker, is that life has no transcendent meaning; that all that we do and are is utterly without cosmic significance. Put simply, what humankind may fear more than all else is that life is without meaning or purpose, that there is ultimately no order in the universe and nothing to which we may anchor our existence. This prospect of chaos is something that we as self-aware animals cannot abide, so we create various defenses against mortality. Ideologies, religions, and belief systems are realities human beings generate to project order onto the potential chaos of the unknown and, having created a meaningful order, we will sometimes stop at nothing to preserve it. To do otherwise is to surrender to the possibility that life is utterly and totally insignificant.

Sociologist Peter Berger has argued that humans will engage in almost any behavior that is believed to ward off chaos, including self-destruction, if it is done in the name of some overarching meaningful order, or what he refers to as a nomos. In this

sense, when confronting death and sacrificing himself or herself, the suicide bomber establishes the significance of his or her particular version of Islam and ensures a meaningful place in the order of things for all cobelievers. Indeed, the mujahidin may well be convinced that all humankind will ultimately benefit from any actions that serve to harmonize humanity with the wishes of Allah. All are sacrificed to establish meaning and purpose for the human enterprise.

Given recent history, many have tried to come to some understanding of violent jihad and terrorist logic looking at various sociohistorical dimensions. Like the story about the blind clerics and the elephant, each perspective may capture only part of the phenomenon, but combining them—the economic, political, religious, cultural, and social psychological—can broaden the conversation and perhaps contribute to a resolution of one of the world's most intractable problems.

Kamikaze Pilots

At the end of World War II, as a last ditch effort the Japanese military instituted the *tokkōtai* (or kamikaze) operations, in which pilots were asked, as a one-way mission, to dive into American aircraft carriers. Their voices defy the prevalent stereotype of "crazy chauvinistic zealots":

> "It is easy to talk about death in the abstract, as the ancient philosophers discussed. But it is real death I fear, and I don't know if I can overcome the fear."
>
> "Even for a short life, there are many memories. For someone who had a good life, it is very difficult to part with it. But I reached a point of no return. I must plunge into an enemy vessel."
>
> "To be honest, I cannot say that the wish to die for the emperor is genuine, coming from my heart. However, it is decided for me that I die for the emperor. . . ."

These words from Hayashi Ichizō, a graduate of the Imperial University of Kyoto who died on April 12, 1945, succinctly portray the death imposed on the young men who died as kamikaze pilots. In their opinion, they did not commit suicide, and no Japanese believed they did either.

Toward the end of World War II, when an American invasion of the Japanese homeland seemed imminent, Ōnishi Takijirō, a navy vice-admiral, invented the tokkōtai (Special Attack Force) operation, which included airplanes, gliders, and submarine torpedoes, none of which was equipped with any means of returning to base. Ōnishi and those closest to him thought that the Japanese soul, which was believed to possess a unique strength to face death without hesitation, was the only means available for the Japanese to save their homeland, which was surrounded by American aircraft carriers whose sophisticated radar systems protected them from being destroyed by any other means. Of the approximately 4,000 tokkōtai pilots, about 3,000 were so-called teenage pilots, who were drawn from newly conscripted and enlisted soldiers and enrolled in a special pilot training program. Close to 1,000 were student soldiers, university students who the government graduated early in order to draft. Although exact figures are hard to find, the available data shows the majority of those who died in the tokkōtai operation were student soldiers who were quickly promoted to officers. Of the 632 army officers who perished, 71% (449 pilots) were student soldiers; and of the 769 navy officers who perished, 85% (655 pilots) were student soldiers.

Unfortunately, the teenage pilots left almost no written legacy, but the writings left behind by the student soldiers offer invaluable testimony to these young men's struggle to sustain their connections to the rest of humanity amid the wrenching conditions of war and to make meaning of a death they felt was decreed for them. These extraordinarily well-educated youth were reflective and cosmopolitan, able to read the classics as well as the philosophies

and literature from Germany, France, Russia, and elsewhere, sometimes in the original language. They drew on their knowledge of philosophy and world history to try to understand the situation in which they inadvertently, but inescapably, were placed. Many of the student soldiers were political liberals or even Marxists or other radicals.

Since the end of the 19th century, as Japan began to modernize, the Japanese government faced the fact that Western colonialism was encroaching into the Far East, with Japan being the only nation that was not colonized. The first task for the Meiji government was to build a strong military, for which they adopted the motto, "Thou shall fall like beautiful cherry blossoms after a short life." This motto was relentlessly disseminated through textbooks, school and popular songs, films, theatrical performances, and so forth. This was the darkest period in Japanese history for young men. From elementary school onward, they were told that their lives should be sacrificed for Japan *qua* emperor. The Tōjō government graduated university students early twice, and all graduates, other than those in education and the sciences, were drafted.

Those who were forced to "volunteer" to be kamikaze pilots repeatedly said they feared death, and many said that they would rather die soon, rather than wait in uncertainty. Because these soldiers were assigned to these missions, they really did not commit suicide. Some stated that the government murdered them. They were similar to those soldiers from any nation or society who were drafted and sent to battlefields where death was guaranteed.

These young pilots read thousands of books trying to find meaning and rationalize their death at such an early age. Most of them were not married, and while some had experienced only platonic love, others were intensely in love with women they had to leave behind. As their death approached, they wrote more and more poems, crying out for their mothers and lovers. Hayashi Tadao, a graduate of the Imperial University of Kyoto, wrote a poem the night before his death on July 27, 1945:

Dusk, that most beautiful moment…

With no pattern

Appear and disappear

Millions of images

Beloved people.

How unbearable to die in the sky.

Kasuga Takeo, who looked after the daily routines of the student soldiers at the Tsuchiura navy airbase, describes how the night before their final flight turned into mayhem. They drank cold sake—some broke hanging light bulbs with their swords, others threw their chairs through the windows, while others tore white tablecloths. While some shouted in rage, others wept aloud. They thought of their parents and lovers. Although they were supposedly ready to sacrifice their precious young lives the next morning for Imperial Japan and for the Emperor, they were torn beyond what words could express. Some put their heads on the table, some wrote their wills, and others danced in a frenzy while breaking flower vases. The next morning, they all took off wearing the rising sun headband. Kasuga wrote how this scene of utter desperation, which he saw with his own eyes, had hardly been reported. He added that they had gone through incredibly strenuous training, coupled with cruel and torturous corporal punishment as a daily routine, only to be sent off to their death.

Karoshi

Karoshi means "death from overwork." Although the direct cause of death may often be a heart attack or stroke, the concept of karoshi implicates mental and physical exhaustion from an excessive workload over a long period of time as the underlying cause of such fatal physical ailment. The phenomenon first received public recognition in Japan in the 1980s, during the period of rapid economic growth and an increased work demand on corporate employees. Similar phenomena are also reported in other industrialized nations, such as the United Kingdom and the United States.

Throughout the 20th century and particularly during the post–World War II era, Japanese corporations emphasized teamwork and employees' loyalty to the corporate collective as a means to increase efficiency and productivity. They developed a human resources strategy to nurture these values in their predominantly male core employees, including lifetime employment, or the practice of retaining their employees for the length of their career whenever possible, and seniority-based promotion, or the pay scale that depends on the length of service, instead of performance or qualification of individual workers. Corporate employers rewarded their loyal core employees with generous compensation, both tangible and intangible, and encouraged social activities among employees to build a sense of belonging. In turn, male core employees, who are often referred to as "salarymen," became highly dependent on their corporate employment, both financially and psychologically. In general, these strategies were highly successful, and Japanese corporations and the economy throughout the latter half of the 20th century greatly benefited from this system.

The emphasis on teamwork and loyalty has also had significant effects on the day-to-day work practice in Japanese corporations. Unpaid overtime—in which employees do not declare their overtime work and therefore perform additional duties without pay—has been a routine practice that workers often understood as necessary and obligatory at times of high work demand, even if their supervisors did not specifically ask. In addition, the majority of Japanese workers hesitate to leave work at the official closing time of 5 p.m. if anyone else in their team or section was staying behind. Finally, the line between work and leisure is often blurred, or even nonexistent, as many salarymen's social network is almost exclusively based in their world of work. Thus, after work social activities and weekend outings with coworkers, bosses, and/or clients cut further into already diminished personal time. As a popular 1980s television commercial portrayed, Japanese salarymen are expected to "work 24 hours a day" and be the most productive *kigyo senshi* (corporate warrior).

Within the context of this work environment, it is not at all surprising that karoshi became a major social issue in the 1980s, as Japan was entering the unprecedented *baburu* (or bubble) economic boom. During this period, Japan's economic machinery was literally in a frenzy, and there was, it seemed, always more money to be made, which meant for an ordinary salaryman, more work to be completed every day. Because of the deeply instilled ideology of corporate loyalty, many of these workers obliged without hesitation. It was not unusual for them to stay in the office until 11 p.m. or midnight, 6 to 7 days a week, and work 70 to 80 hours per week on a regular basis. If work hours in themselves seem inhumane, the pressure to meet tight deadlines and outdo ever-stiffening competition also exacerbated the level of stress that these workers experienced.

While exhaustion and even death of salarymen from excessive work demands were an increasingly familiar occurrence among Japanese workers and their families throughout the 1970s and the early 1980s, there was little public recognition of the linkage between overwork and sudden death. Families of karoshi victims were not entitled to receive Workers' Compensation benefits and were often forced to depend on the largesse of their deceased breadwinner's employer, who often paid out a substantial sum of money to the family. In return, families often refrained from airing their grievances in public arenas.

In the latter half of the 1980s, families of karoshi victims began to take their cases against the corporate employers and the Workers' Compensation Program to court, and this was when karoshi became a highly visible social problem. The Japanese Ministry of Labor, protective of corporate interests, was reluctant to acknowledge the legitimacy of karoshi claims, and the only

support system available to the victims' families came primarily from grassroots organizations, such as the National Defense Counsel for Victims of Karoshi, an organization of attorneys concerned with the legal rights of those impacted by overwork and death.

Legal decisions emanating from Japan's High Courts during the early 1990s established the connection between overwork and sudden death, prompting the Japanese government to make, albeit slowly, policy changes. While situations are improving, karoshi claims continue to be difficult to establish under the Ministry of Labor guidelines, and many families of karoshi victims, discouraged by a prolonged and burdensome process, do not file a claim for compensation.

The face of karoshi began to change in the 1990s, however, as the bubble economy abruptly ended and Japan entered a long period of recession, known as *Heisei Fukyo*. While the work demand appeared to ease up, different sources of stress began to affect corporate workers. Japanese corporations began radical restructuring and downsizing to survive in the global competition, and corporate paternalism eroded quickly. Layoffs caught many salarymen by surprise. They assumed that they had a stable job for the rest of their productive lives. Those who were able to hold on to their jobs discovered that their workplace turned into a place of severe competition where each individual worker is held responsible for establishing measurable results. Overworked, alienated, and stressed beyond their limit, Japanese workers in their midcareer increasingly began choosing death to escape the situation, and the suicide rates significantly increased during the late 1990s and early 2000s. Many of the suicide cases are thought to be *karojisatsu* (suicide triggered by excessive stress from work), a new subcategory of karoshi that reflects Japan's changing economic reality.

Kübler-Ross's Stages of Dying

Elisabeth Kübler (1926–2004) described herself as stubborn, opinionated, independent, and unconventional. As a youth growing up in Switzerland, she was determined to become a doctor despite a childhood experience of hospitalization in which she was isolated and separated from her family by what she viewed as an impersonal and uncaring system.

After qualifying as a physician and marrying a fellow medical student from America, Emanuel ("Manny") Ross, the couple moved to the United States. As a new doctor, Kübler-Ross accepted a residency in psychiatry because becoming pregnant disqualified her from one in pediatrics.

In the fall of 1965, Kübler-Ross was a faculty member at a University of Chicago hospital when four theological students asked her to help them understand death as the ultimate crisis in life. She offered to identify dying patients with whom to conduct interviews, but many of the other physicians at the hospital were critical of their new colleague. They were concerned about exploiting vulnerable patients and unwilling to grant access to their patients. Still, by early 1967, Kübler-Ross was leading an unorthodox but popular weekly seminar in which she would interview a patient behind one-way glass with subsequent discussion after the patient had left.

In 1969, an article in *Life* magazine and publication of what was to become an international best seller, *On Death and Dying,* led to worldwide fame and countless requests for Kübler-Ross to give

interviews, lectures, and seminars on subjects that soon became the focus of her professional life.

Kübler-Ross had views on many subjects, including the afterlife, spiritual guides, out-of-body experiences, and near-death experiences, but she is best known for her theory of the five stages of dying.

The Five Stages

The stage theory of dying arose from interviews that Kübler-Ross conducted with some 200 adult patients over a period of roughly 3 years. Each of the stages can be associated with a typical expression.

Stage	*Typical Expression*
1. Denial	"Not me!"
2. Anger	"Why me?"
3. Bargaining	"Yes me, but…"
4. Depression	
Reactive	Responding to past and present losses
Preparatory	Anticipating and responding to losses yet to come
5. Acceptance	Described as a stage "almost void of feelings"

Each stage of the theoretical model represents a typical human reaction:

1. Denial involves reactions to the shock of the diagnosis. It reflects unwillingness to acknowledge or outright rejection of the fact that one is dying. Denial is also a kind of protective barrier aimed at holding off the implications of terminal illness.
2. Anger arises when denial can no longer be sustained. It at least partially acknowledges that the individual is dying but also complains this is not fair or right. Anger is often projected toward care providers, God, or other perceived contributors to the illness.
3. Bargaining involves resignation combined with efforts to regain some degree of influence by focusing (realistically or unrealistically) on what might be done to postpone death or arrange for that outcome to occur in ways more acceptable to the individual in return for pledges of various types to God or the doctors (Kübler-Ross did not expect most individuals to keep these promises).
4. Depression focuses on the individual's sense of loss, either on past and present losses, or on future, anticipated losses, such as the expected loss of all love objects.
5. Acceptance is described as a reaction when the end may seem positive or there may not be enough strength to live. Different individuals may experience acceptance in different ways, ranging from looking forward to impending death as relief from suffering or an opening to the afterlife, on the one hand, to grudging acknowledgment of one's fate, on the other hand.

Kübler-Ross suggested that with adequate time and support dying people can or may work through each of these five stages. She emphasized that hope usually persists throughout, informing care providers of the importance of allowing dying people to sustain hope, whether or not the care provider agrees with the form hope takes. This important aspect of the theory has often been overlooked.

Appreciating the Goals of the Theory

Kübler-Ross wanted to tackle the depersonalization and dehumanization she found to be a critical aspect of the experiences of many dying people. She believed the attitudes of care providers and health care systems often contributed to the loneliness and isolation perceived by many dying people, as well as their sense of helplessness and hopelessness. She emphasized the importance of "taking the role of the other": to imagine oneself in the position of these patients, to try to understand their reactions rather than judging them, and to seek to learn from them.

Kübler-Ross variously described the five stages as reactions, defenses or defense mechanisms, coping mechanisms, and adaptations. She depicted her theory as a general model or categorization of experiences many individuals have when facing awareness of their own finality. According to Kübler-Ross, each stage can last for different periods of time in different individuals. Some stages may replace others, while others may exist at times

side by side. In other words, the five stages represent a typology of some prominent psychosocial reactions to experiences that may be associated with dying. Kübler-Ross also argued these types of reactions are not confined solely to dying people. Indeed, as important components of the human experience, these reactions may also be experienced by others who enter into the experiential world of those who are dying, including family members and care providers.

Kübler-Ross described the five stages in her theory in broad terms. For example, denial and acceptance are essentially presented as opposites on a continuum. Although the other three stages—anger, bargaining, and depression—may vary in intensity, character, and focus, they appear mainly as transitional reactions experienced in the process of moving from denial to acceptance. Denial and acceptance are each formulated in ways that allow them to apply to a spectrum of reactions: from a complete rejection of one's status as a seriously ill person to an unwillingness to admit one is dying or that death is more or less imminent, on one hand; and from acknowledgment, resignation, and acquiescence to welcoming death, on the other hand.

Denial is described as a healthy way for dying people to cope with their situation. Kübler-Ross wrote that almost all patients use at least partial denial, both during the initial confrontation with serious illness and also later on from time to time. Denial serves as a buffer against unexpected and shocking news, while enabling individuals to collect themselves and, perhaps with time, to mobilize other less radical defenses.

Evaluating the Stage Theory of Dying

The model proposed by Kübler-Ross helps normalize and humanize the experiences of dying people by demonstrating that dying is a human process, not merely a series of biological events. It drew attention to challenges encountered by dying people and to their needs as living human beings. The theory became readily accepted within the popular culture perhaps because it describes reactions to a difficult situation in ways people can easily understand. The model also allows others to contemplate their own reactions when interacting with a dying person. In addition, the theory argues against the view that only mentally deranged or suicidal people could truly accept their deaths. In all of this, Kübler-Ross was an early and important contributor to the death awareness movement. She also helped establish the atmosphere in which the modern hospice movement developed.

Still, there have been serious criticisms raised against this stage theory of dying. First, scientific research has not supported this model. Kübler-Ross herself offered nothing beyond the authority of her own clinical impressions and illustrations from selected examples to sustain her theory. She advanced no further evidence to support or confirm the efficacy of the model, although she continued to assume its reliability as obvious. Nevertheless, there has been no independent confirmation of the validity or reliability of the theory, and the limited empirical research that is available does not confirm this model.

Second, the five sets of psychosocial reactions at the heart of the theory can be criticized as overly broad in their formulation, potentially misleading in at least one instance, insufficient to reflect the full range of human reactions to death and dying, and inadequately grounded for the broad ways in which they have been used. The expansive way in which these five reactions are formulated has already been noted.

Kübler-Ross did not invent these five reaction patterns; her inspiration was to apply them individually to the human experiences of dying and facing death, and to link them together as part of a larger theoretical schema. Among its peers, the stage of depression seems curious as an element in a healthy, normative process of reacting to dying—unless it really means sadness—because clinical depression is a psychiatric diagnosis of illness. Moreover, we need not believe there are only five ways in which to react to dying and death. Finally, Kübler-Ross herself applied this theory to children and those who are bereaved in ways not warranted by its original origin in interviews with dying adults.

Third, the theory has been criticized for linking the five reaction patterns together as stages in a larger process. In part, Kübler-Ross seems to have agreed with this point because she argued for fluidity, give and take, the possibility of experiencing more than one of these reactions simultaneously, and an ability to jump around from one stage to

another. If so, this is not really a theory of stages, which would involve a linear progression and regression like steps on a ladder or calibrations on a thermometer. In short, the language of "stages" seems inappropriate for what are essentially clusters of different psychodynamic reactions to a particular type of life experience.

This last point is important because some have shifted the emphasis of the theory from description (this is how some people react to impending death) to prescription (this is how people should or ought to react to impending death). Thus, some practitioners may create the reality when they inform dying people they have already experienced one of the five stages and should now move on to another, while others complain about individuals who they view as "stuck" in the dying process. When coupled with the limits imposed by only five general categories of reaction to dying, this tends to suppress the individuality of dying people (and others) by coercing them into a rigid, pre-established framework in which they are expected to live out an agenda at the end of life that is imposed on them by others. This is particularly ironic because Kübler-Ross set out to argue that dying people are mistreated when they are objectified and dealt with in stereotypical ways. As a result, what seems to be widespread acclaim for this theory in the popular culture arena and in certain forms of professional education contrasts with sharp criticism from scholars and those practitioners who work with dying people.

Lessons From the Stage Theory of Dying

Three important lessons to learn from this stage theory of dying are implicit in the Preface to *On Death and Dying*. The first lesson is that those who cope with dying are living human beings who will react in their own individual ways to the death-related challenges that confront them and who may have unfinished needs they desire to address. The second lesson is that others cannot be effective providers of care unless they listen actively to those who cope with dying and work with them to identify their psychosocial processes and needs. The third lesson is that we all need to learn from those who are dying and coping with dying—to view them as our teachers—in order to come to know ourselves better as limited, vulnerable, finite, and mortal, but also as resilient, adaptable, interdependent, and worthy of love. Such characteristics can only enhance the human experience.

LAMENTATIONS

Lamentation is the ritual mourning of the dead through the collective rather than individual voicing and physical display of grief, usually over the corpse, prior to inhumation or cremation. The word *lamentation* is derived from Latin *lamenta*, which describes a wailing, weeping, or moaning. Synonyms include *dirge*, *threnody*, and *elegy*, but each term has its own oral and literary tradition. Mourning rituals, within the prescribed time between death and burial, vary according to religion. In the West, the evolution of ancient rites continues to impact contemporary expressions of lamentation.

The ritual of grieving over a corpse is of great antiquity and appears in the Epic of Gilgamesh, when the hero mourns for his companion Enkidu. In ancient Greece, the ritual expression and display of grief were both private and public acts. On the second day after death, the corpse was laid out (*prothesis*) for private mourning prior to the public ceremony accompanying the transportation of the corpse (*ekphora*) for burial or cremation at which lamentation dirges were sung. Lamentation is attested in Homeric epic: During the funerals of Patroklos and Hektor in the *Iliad,* both men and women engage in public lamentation that involves the ritual voicing of grief through dirges, the striking of breasts, the scratching of cheeks, and rolling in the dirt.

Later in Greek culture, however, only women and professional female mourners participated in public lamentation. The earliest depictions of lamentation (8th century B.C.E.) are found on large vases (amphorae or kraters) of the archaic geometric period that served as grave markers in the Dipylon Cemetery in Athens. Stylized representations of mourning scenes include the prothesis of the deceased surrounded by female mourners who lift their hands to their heads as a gesture of lamentation. The Choruses of Greek tragedy often incorporate threnodies in their odes.

The Old Testament book of Lamentations contains lamentations in verse that focus primarily on the destruction of Jerusalem and Solomon's Temple in 586 B.C.E. Although not a part of funerary ritual, the laments still hold religious relevance and are read aloud: Orthodox Jews mark the anniversary of the destructions of both Solomon's Temple and Herod's Temple by reading the verses on the 9th day of Ab. The verses are also read aloud at the Western Wall in the city of Jerusalem. As part of the Catholic liturgy, the verses are read aloud in the final 3 days of Holy Week.

In ancient Rome, funerary ritual was a blend of Greek and Etruscan practices. Early legislation forbade excessive expenditures or prolonged grieving through repeat burial ceremonies to curb aristocratic competition and to avoid extensive contact with corpses. Professional undertakers served as funeral directors who organized public expressions and displays of lamentation at wakes and funerals that were performed by female family members and professional female mourners. Since the middle Republican period (3rd to 2nd centuries

B.C.E.), dirges of lamentation and praise (*nenia*) were sung by a professional mourner to the sound of a flute. Gestures accompanied public lamentation and varied little from the archaic Greek period (8th to 6th centuries B.C.E.), attesting to the universality of a shared physical vocabulary of raised hands, the beating of breasts, and a disheveled and dirty appearance. Spontaneous expressions of grief and lamentation (sometimes accompanied by violent behavior such as the destruction or burning of public buildings and monuments) were often voiced by the urban mob in Rome to show sympathy for the death of a political figure such as Julius Caesar. The literary genre of epicede both elevated the expression of grief and consolation to survivors and extended the period of bereavement into a more private and meditative period of grieving.

The Christian influence on traditional Mediterranean expressions and displays of lamentation was profound and long lasting. The early Christian Church viewed death as a happy occasion because the soul would be reunited with Christ; therefore, Christians viewed contact with corpses less apprehensively than did pagans or Jews (due to baptism) and viewed the departure of the dead as a cause for celebration. Private and meditative mourning through hymns and prayer replaced the public lamentation rituals of pagans with their emphasis on wailing and the self-infliction of physical pain to reflect inner grief.

Mourning remains largely a private and relatively quiet activity (the uncontrollable grief of an individual, however, may always manifest itself at funerals) in the West regardless of religious denomination. Even in Hindu funeral ritual, there is no crying for the deceased during cremation, but grieving is permissible at home. Although the deceased may be remembered in prayer and narratives delivered by family and friends, quiet mourning accompanies the viewing of the deceased in funeral homes and at their burial at which a eulogy or a favorite song of the deceased often represents the grieving sentiments of survivors.

Language of Death

The language of death involves strategies of avoidance or consolation when naming death or speaking about a decedent; it is the use of euphemisms or linguistic tools to soften people's reactions to death and dying. The concept is not to be confounded with *language death*, which is a term used by linguists to describe the disappearance of languages as a result of colonialism, assimilation, government policy, or other social or natural forces. Language, the result of the social need for communication, was initially conceived to name objects from the near environment but has evolved into a complex system, capable of referring to abstract concepts and multiple meanings, including the semantic field of death. The language of death reflects the cultural attitudes toward this event. In modern societies it is used not merely to inform, represent, and reflect upon death and dying, but also to aid in epidemiological, medical, and legal discourses on decedents and their survivors.

Emergence of the Concept

Studies on Euphemisms

Questioning about death and beyond has been an ontological matter that goes back to the origins of mankind; however, there was little scientific concern about it up to the past century. As early as 1936, Louise Pound began reflecting upon American euphemisms for *dying, death,* and *burial,* but it is only more recently that scholars in the field of human sciences have begun researching how language is appropriated in communications about death and dying.

Subsequently, scholars point out that in the mid-19th century a shift in the conceptualization

of death occurred. Prior to the Romantic period, the language of death was replete with expressions such as *to pass over, to go home, to (be carried to) rest, to fall asleep*. These expressions were intended to help survivors cope with their loss, or rather the event of death itself. According to the anthropological point of view, death is a timeless taboo, the naming of which usually calls up superstition of contamination from the concept to the object. This is useful to explain the universal use of metaphors, euphemisms, and slang to represent *death, dying, the deceased,* and *burial*. The use of metaphor is pervasive, as shown in studies on primitive societies. Besides, in civilizations with written traditions, while literary works never really considered the moral interdiction, the language of death continued to flourish, and a rich semantic field developed around the typology of death.

Nowadays, the language of death is expressed through the vernacular, but also the religious, the medical, the legal, and other scientific terminologies (demography, sociology, etc.). Most of them have euphemistic ground: For example, *cemetery* comes from the Greek word for "dormitory," *euthanasia* from "good death," and *casualty* meant "accidental loss" up to the Crimean War. The study of etymology also shows that the use of metaphors has a long tradition in the reference to death and the technical concepts inherited from it. In some cases, the linguistic turns soften the approach to death, whereas in others they bring forth value interpretation (e.g., *suicide vs. autolysis, euthanasia vs. well dying*). Contemporary concern is to avoid social stigma and moral judgment; thus the language of death is contextually dependent.

Linguistic Taboo and the Cultural Paradoxes

In modern societies, scientific progress moves the dying from their homes to medical institutions with the consequence of excluding them from their familiar surroundings and daily conversations. Thus, death returned to being a linguistic taboo. Later, the industry of preprinted condolences developed stereotyped all-inclusive formulas to express personal messages of sorrow while mourning the dead.

In 1969, scholars began writing on the importance of finding a place for the dead among the living in order to fight over these attitudes of disinterest. In practice, since the late 1990s, *Vivre son deuil* (Living With Mourning), a European organization, has encouraged survivors to speak about their grief in order to free their phantasms and fears about the life beyond. Hope and consolation are gently encouraged.

Current Attitudes of Survivors

The language of death offers a way to think about and to discuss death that is reflective of the extant cultural attitudes that surround end-of-life processes, as well as representations of grief and mourning. Since the end of World War II, on both sides of the Atlantic, humanitarian organizations have been struggling to defend civil rights by using correct language with respect to death. According to the experience of volunteers, silence can be encouraged as a humble attitude of respect for the loss of the decedent's survivors and as a protection against stereotyped formulas. Thus, traditional and psychological models of bereavement highlight the emotional aspect in the process of recovery. Sometimes neglected in modern societies, rituals also reflect cultural and linguistic patterns about death.

Additionally, Ruth Menahem argued that language was a medium for impulsive representations to express themselves, so that unconscious desire might accede to the conscious mind. However, there is no language without desire, and the only desire that all humans accomplish is their wish to die. Thus the study of language is helpful. It is a means to understand human attitudes toward death.

Speaking of Death in a "Proper" Manner

In many cultures, the language of death is constantly revised and adapted to social realities. The medicalization of dying, in its conception of death more as a process than as an event, rendered the subject of death elusive and even obscene to the common man.

There exists a schism between the effort to humanize medical language and the scientific need to be more explicit and less ambiguous about death and grief. In the latter instance, common expressions are misleading, especially among children who remain confused in the hope that the "departed" may come back. Most adults in turn

consider that the way in which they are informed about the death of their beloved ones has a great impact on the entire process of mourning and recovering. Doctors and policemen are therefore trained to adopt an allusive approach to informing about death rather than a direct one. All in all, the word *death* evokes strong emotions, but it seldom allows a satisfactory alternative.

The language of death is crucial for professionals and volunteers who deal with grief, mourning, and bereavement. However, a rigid labeling of the steps involved after a loss induces the risk of "iatrogenic injury" (injury contracted inside the medical institution). An appropriate discourse on death can help survivors recover from their loss. Professional language itself is submitted to this social norm, especially with regard to critical terms such as *euthanasia, physician-assisted suicide,* and *murder.* Accordingly, it is recommended that physicians should use a specific form of language when speaking with peers and another, more vernacular form when addressing families. If guilt and social stigma are to be avoided, the use of appropriate words becomes a crucial aspect of medical management.

A Humanistic Approach

In modern societies, the professional and profane are no longer separate; thus, language generally suits the psychological needs of speakers. Rewording is required in order to adapt scientific terms to the reality of the human condition. The French thanatoanthropologist Louis-Vincent Thomas wrote about the important use of appropriate terminology when death by suicide is involved, noting that the general discourse about suicide is linguistically aggressive. Words constructed with the root *cide*, from the Latin *caedere* meaning to kill, are linked to the idea of interpersonal violence (*fratricide, genocide, homicide, matricide, parricide*) and therefore easily attached to sin and guilt. That is why the English language, through the Oregon Death with Dignity Act of 1994 and the California Compassionate Choices Act of 2007, offers such expressions as *aid in dying, choice in dying,* and *end-of-life choices* as preferred to *assisted suicide.* These linguistic turns are meant to protect the medical staff and patients either from accusation of unkindness or from stigma associated with the use of the word *suicide*.

Legal Responsibilities

For a long time, technical terms were employed alongside vernacular ones in the scholarly literature on the language of death. Euphemisms arose, particularly in the medical realm, but more concrete terms were needed for legal purposes. Current studies suggest that because legal decisions are influenced by clinical language, it may be necessary to more clearly designate the clinical process of death.

For instance, after the attacks of September 11, 2001, the New York City Office of Chief Medical Examiner considered that the deaths of people jumping from the World Trade Center towers should be recorded as homicides and not suicides. In 2005, a Gallup survey showed that 75% of the people interviewed were favorable to the "end-of-life" decision, but only 58% accepted the idea of "assisted suicide." In this context, causes of death as recorded in medical certificates have a determinant influence on decisions insurance companies make regarding payment of policies and sometimes on what sort of religious sermons are given at funerals.

Suicide: A Controversial Concept

The contemporary preoccupation with suicide as a major problem of public health, as well as the means to prevent it, led to the development of a language of suicide, which includes transparent terms that contain no subjective judgment. Suicide is still depicted as a sin, a crime, and as proof of alienation. The existing language surrounding suicide is therefore marked with social stigma or legal sanction even where legal institutions, insurance companies, and churches have reformed their attitudes toward this kind of death.

According to the French Ph.D. Pierre Satet, confusion may come, on one hand, from mass media reporting differently the death of a celebrity and that of a noncelebrity. Constrained by economic and commercial interests, newspapers give more space in their columns for the former. Paraphrases such as "to put an end to one's days" are therefore more likely to appear with reference to a film or rock star, for example, while the word *suicide* is more often used with reference to common people. On the other hand, there is little consensus among medical staff, who may use *suicide* and *autolysis*

interchangeably even though these words do not refer to the same clinical phenomenon. However, Satet thinks that the most inappropriate use is *recidivism* for repetitive suicide attempts: Coming from legal terminology, this word is defined in dictionaries as the commitment of a new crime once the person has already been condemned.

In this context, one of the aims of the regional programs of health is to try to change society's perception of suicide. Consequently, Satet proposes to replace the word *autolysis* by *suicide, recidivism* by *repetition, recidivist* by *primo-* or *multi-suicidant,* and so forth.

The general conviction is indeed, as the writer Albert Camus put it, that to name things improperly is to add to the misery of the world.

Last Judgment, The

The Last Judgment, or Day of Judgment, is a theological belief that refers to the last day of earth's history in which the faith and "faith enacted" of every person who has ever lived is reviewed by God. While all of the main world religions have this concept embedded in their religious belief systems to some degree, it is in the theological texts, statements of beliefs and liturgies of Christianity, Judaism, and Islam that this concept is most clearly delineated. Despite the differences in beliefs, outlooks, or conception, the unifying understanding is that this is the time when God, the initial creator being, completes the cycle of humanity's history by finalizing or doing away with the issue of sin and its linked consequence of death, and commences or creates a new earthly form of paradise.

Despite the large range of differences in theological perspectives, there are a number of similar concepts and understandings that underpin the various belief structures of the Last Judgment. While not inferring there is unity of belief among the commonalities of focus with regard to this area, the one persistent common denominator is the notion that death for believers is no longer a factor in their continuing existence. Thus, this entry uses the notion of death as a means to delineate the foundational elements that relate to the Last Judgment as a holistic uniting perspective.

Concepts of Language, Death, and Judgment

For the majority of the world's great religions, the texts that detail and describe the Last Judgment are couched in a genre and associated language use that is typically eschatological (deals with the times of the end) and in many cases apocalyptic (deals with God interceding directly into the affairs and time of humanity). The language use of these texts is one typified by symbols and metaphors as seen in the Christian books of Revelation and Daniel. While there are various forms of exegesis related to apocalyptic literature across the religious belief systems, it is generally accepted that despite the difficulty in understanding the precise meanings of these symbolic forms, when it comes to the associated meanings of death in these texts, the meaning and implications are much clearer. The overall

language use is intended to reveal the devastating effects that God has on unbelievers when He directly steps into the human world to execute final judgment. In a general sense, the Day of Judgment for believers represents a final and everlasting release from death, whereas for unbelievers it represents a total and eternal separation from God through a perpetual death or a life in hell, or Hades. An example of this release from death is found in the second chapter of the Christian book of Revelation in which believers are said to not suffer "the second death," which is a reference to being vindicated or redeemed in the Last Day Judgment. The sense of being separated from God, or suffering the "second death," is found in chapter 4 of the same text in the symbolic entrance of the Four Riders of the Apocalypse. Both of these motifs are also found as reoccurring themes in the last five chapters of Daniel, an apocalyptic and eschatological text (in the Old Testament Christian canon) held as the epitome of overcoming the curse of death and evil for both Jews and Christians.

A similar set of eschatological motifs are also found in the Qur'an. For Muslims, the Final Judgment involves each person being handed a "book of their deeds," which lists and details all of their thoughts, actions, and utterances (Qur'an 54.52–53). Using a similar metaphor as found in the Christian canon, if believers are given the list of deeds in their right hand, they lose the possibility of death forever and enter the gates of paradise. However, if handed over to their left, they forfeit a life of pleasure and suffer the "living-death" sentence and enter hell.

Concepts of Atonement, Death, and Judgment

As one of the key metaphoric threads that run through the religious texts of Islam, Christianity, and Judaism, and in particular the apocalyptic texts, is the concept of atonement. Literally meaning "at one with God," while prominent in Judaism and Christian thinking and belief structures, it is held within Islam as a ceremonial reminder of Mohammed's tripartite role of prophet, priest, and wandering leader through a series of rituals. The unifying narrative in all three religions that clearly highlights the Judeo-Christian tradition of needing an intercessory sacrifice, and reveals Islam's link to its ideals of priesthood, is the story in which God calls Abraham to sacrifice his only son, Isaac. However, in this narrative just as Abraham is about to kill his son God intercedes by providing a ram caught in a thicket. The Judeo-Christian belief structure believes this is a metaphor for humanity's need of priest-intercessor to act as a substitutionary death as the human condition alone falls short of the requirements to enter heaven. In Islam this intercessory death narrative is reiterated through the Feast of Sacrifice, held simultaneously across the Muslim world, which celebrates the Abrahamic atonement sacrifice as a symbol by which Mohammed celebrated the unifying conquest of this new religious faith over an older form. While there are obvious differences in perspectives among these religions, the atonement metaphor can also be seen to represent a restructuring of a new world and a new life in which death has been eliminated. This atonement process also entails the setting up of the universal sovereignty of God and the establishment of a reign under which God's enemies are finally destroyed and God's people are converted and gathered into a redeemed land or universe. Through the ending of death, the final kingdom of God is given life.

Another link to the atonement concept is the Judaic festival of Yom Kippur, a festival that symbolizes the ultimate death of sin. Held at the end of the Jewish year, it is also symbolic of the Last Judgment in that in the original sacrificial mode, the accumulated sins of the entire Jewish nation were figuratively placed onto a "scapegoat" representing Satan and then sent into the desert to die. Thus, sin was metaphorically killed forever, leading to the Last Judgment in which atonement would reach actuality. For many Christian denominations, this notion of Yom Kippur has a twofold application in that Christ became the scapegoat and through his own death he vicariously carried the sins of the world into nonexistence. At the end of days, or the Last Judgment, this sin burden will be placed on Satan, the instigator of this problem, who once and for all carries the sins he is ultimately responsible for into final oblivion, namely, the depths of Hades. Thus, death will no longer exist in God's universe.

It is at this point that one of the critical elements related to death, the concept of time, is also finished. Generally considered to be one of the key fears of all humanity, as each day brings the living

human one day closer to the ultimate fear, death itself, it is at the Last Judgment that eternity commences for those redeemed from the curse of sin. The concept of immortality ushered in by the completion of the Last Judgment is not only characterized by a rejoicing as the redeemed finally enter paradise, but the tyranny of time, which has a constant earthly focus of impending demise, is also considered by many religious texts to be a key facet of this happiness. Thus, not only are the saved made *at one with* God, but the three elemental facets of the universe—time, space, and matter—are also freed from the connection with death.

Concepts of Messiah, Death, and Judgment

One of the commonalities found in world religions and how they view the concept of the Last Judgment is the need for a messianic figure to return to the earth to either usher in the period of the Last Judgment or execute the actual judgment process. Notwithstanding the variations of belief in this regard between Qur'anic, Old Testament, and New Testament scholars, there are also a number of various understandings within each of these belief systems. However, in summarizing and synthesizing these variations, in each perspective the Last Judgment is typified by a resurrection of the dead to face judgment either for the deeds or faith. This resurrection typically takes place immediately before or with the simultaneous appearance of the Messiah. For Christians, the Second Coming of Jesus initiates this reappearing of the deceased in tandem with the complete destruction of the earth and, as stated previously, commences the Last Judgment. Islamic scholars also generally believe that the Last Judgment will be characterized by the death of all creatures, an earthly devastation process, and Second Coming of Christ. However, in Islamic eschatology the Second Coming of Jesus in itself precedes the coming of the true Messiah, the *Mahdi*, or the one who comforts, guides and protects. The Mahdi then unites all Islam and defeats the enemies of this now united force.

Critical Concepts of Death and Judgment

This discussion revolves around several key facets of current theological debate and investigation. The first is the notion of what actually happens at the point of death. The traditional Christian belief is that the living body has a separate and distinct "soul" component that departs at the point of death to enter into an initial judgment determining an ongoing existence in heaven or hell. However, new etymological Old Testament research now suggests that perhaps the original Hebrew word details the body as "being" a living soul. In concert with several verses of the Old Testament and a few key points of theology from the writings of the gospel author Paul, it would appear that alternate view of the death-soul relationship exists. This alternate theological point suggests that when death occurs, the body as an entire physical-spiritual entity dies and awaits a final resurrection.

Logic would then suggest that the believer is not fully redeemed until death is finally decreed to be eradicated by God at the Last Judgment. This is perhaps the actual meaning of *the second death* in that believers enter eternal life at the Last Judgment, and nonbelievers suffer eternal separation from God or actually die an "eternal death."

Another key theological aspect that is yet unresolved in Christianity is the concept of the millennium, or the period that is often determined to be 1,000 years of peace that occurs either before the coming of the Messiah or after his appearance. While this may appear to be a side issue, this focus has been recently recognized as a critical factor related to the notion of death in that questions are being asked as to what actually happens at death, and between death and the resurrection. There is also a growing theological perspective that aligns itself with the Islamic view that the millennial period occurs prior to the arrival of the messianic figurehead, and this period is a one of worldwide destruction and disasters. In regard to the Last Judgment, the death of an individual and the death of the world appear to be intertwined.

Last Will and Testament

A last will and testament is a document that describes how a person desires to have his or her property distributed after death, who that person wants to be in charge of settling his or her estate, and who he or she nominates to raise underage children. Usually this document is written by an attorney to ensure it meets the legal requirements of the state where the person lives. However, it can be handwritten or created using outlines in kits that can be purchased commercially. The document should be signed in the presence of witnesses who will not benefit from it and who can verify the signatures.

AARP (formerly known as the American Association of Retired Persons) researchers report that only 60% of Americans over the age of 50 have a will, and even fewer under that age have one. Most people do not like to think about tasks such as writing a will. However, having a plan for one's death, whether or not death is expected, can prevent many family-related problems. Making a will is one way to care for people who are important in one's life. When one's desires are specified and what may be perceived as apparent inequities are explained, there are likely to be fewer disputes and other types of problems after death. Having a will can also save money, and when life events bring about change, a will can be modified.

Today the term *will* is typically used whereas in the past, many people referred to this document as a "last will and testament." Technically, the testament refers to personal property, but today people seldom use this term.

Why a Person Should Have a Will

Anyone who is 18 years old or older and who has a "sound mind" can make a will. A will gives greater assurance that dependents will be taken care of and that property will be distributed as desired. A lawyer should help phrase it in the appropriate legal terms so that it will be read by the probate court as the person it is written for intended it to be interpreted.

A will can provide for equitable treatment of children. That does not mean each child necessarily gets exactly the same things. It is possible to provide for special needs and explain intentions in a will. Moreover, one can nominate a guardian for minor children in the will. Although the court must appoint the guardian, by creating a will parents can establish who they desire to raise their children.

A will can also be used to nominate the executor of the estate, or the person who will settle the specifics of the estate. Again, only the court can appoint the executor, but if the person nominated meets the state requirements and is willing to serve in this capacity, then the court will likely appoint the person nominated. Through a will, a person can specify that his or her personal representative serve without bond or surety. If bond is not required, then the administrative cost of settling an estate is considerably reduced.

A will should simplify the distribution of property and thus shorten the time required to settle an estate. If a person dies without a will, which is called dying intestate, then state law in effect at the time of death will specify how property will be distributed. Thus, everyone has a plan even if this plan does not represent the desire of the deceased. For example, state law often specifies that when a parent dies without having a will, the surviving parent will receive a third of the estate; the children will share the remainder. The surviving parent will have to regularly prove to the court that he or she is managing the minor children's assets appropriately. But a will can specify that the surviving spouse will receive the entire estate without requiring proof that financial decisions are made in the children's best interests. Finally, a will can provide for the full distribution of assets in case of simultaneous death of an entire family through a common event.

When a person without a spouse or children dies, state law might specify that the estate be split

equally among the deceased's siblings. The state's plan for assets will not direct any of them to a favorite charity or someone who was important in the life of the person who died but was not related by blood or marriage.

Major Components of a Will

There are three primary requirements: First, the provisions of the will must express testamentary intent (the person's intent to make a will) and the contents only become effective at the testator's (the person's) death. Second, the will must be in writing (no verbal wills are valid), dated, and properly signed by the testator (the person). Finally, the testator's signature must be witnessed by at least two, preferably three, competent witnesses. These should be people who will not benefit from the will and who are younger than the person so that they are likely to be available when needed. They must sign the will at the testator's specific request and should also sign the will in each other's presence. This will prevent the necessity of proving that their signatures are valid when the will is probated.

A will can be changed by a codicil, which is executed in the same manner in which a will is executed. It can remove, change, or add sections to the original will. Execution of a later will voids all previously made wills. Thus, a lawyer's help is recommended in writing a will so that it meets the state's legal requirements for transferring property.

Process of Creating a Will

Although the procedure is not complex, the creation of a will requires one to do the following:

- List all real and personal property, indicating how the property is owned. In the case of joint tenancy with right of survivorship, the property automatically goes to the other owner(s) when one dies and thus is not affected by a will.
- Indicate how the property should be distributed, especially property with large financial value. Instead of listing every item of property in the will itself, a person may chose to attach a list that specifies what happens with each item. Explanations are not required for these decisions but, in some cases, it is helpful to provide information about the property.
- Nominate an executor for the estate, the person who will settle the estate. Some states have specific requirements for this person, such as the requirement that the executor reside in the state where the estate is being settled. The will may designate the representative be compensated, either financially or with items.
- For those who have minor children it is important to nominate a guardian(s) who will assume the responsibility for raising the children should the parent die prior to the legal age by which adult is defined.
- Get a lawyer to draw up a will so that it is written in the legal terms that allow the probate court to ensure desires are fulfilled.
- Have two or three copies of the will made. Sign one copy of the will in the presence of at least two, preferably three, witnesses who are not named in the will and who will not benefit from it. They will also sign it. After the death of the person who writes a will, the court will ask them to verify the signature on the will and to avow that the person who signed it appeared to be mentally fit and was not forced to sign the will.
- Keep the will in a safe place. Many people place a signed copy in a bank safety deposit box, request their lawyer keep a copy, keep a copy at home, and perhaps give a copy to the person nominated as personal representative. In some states, bank safety deposit boxes are sealed at a person's death and their contents cannot be accessed until a personal representative is approved by the court to settle the estate. Thus, it is important to understand the applicable state's laws concerning this issue. A will should be placed where it will not be damaged or discarded. The will should be kept in a place where it can be readily found when needed.
- Periodically review the will to see if changes are needed. Over time situations change as people marry, divorce, or die, and as new family members are born. It is particularly important to have the will reviewed if one moves to another state. It is also important to recognize that the way that title is held on property takes precedence over a will.

The Standard Form

Standard forms for creating a will are available in bookstores and other readily available venues.

These may provide a format for a will and help one identify all the information that is needed in a valid will. State law has the most influence on the issues that are addressed by wills. Although an attorney will create a will based on the client's desires, most state legislatures reevaluate estate law on a regular basis. For this reason a will should be periodically checked by a lawyer to ensure the document is in conformity with state requirements.

Letter of Last Instructions

Placed in a sealed envelope marked "Letter of last instructions, to be opened after my death" and followed by a signature, the letter of last instructions is an important document. Although many people believe that information pertaining to burial and memorials is included in a will, it should instead be in a letter of last instructions that will be read immediately upon death. Whereas the will generally is read after burial or a memorial service is conducted, a letter of last instructions is appropriate for specifying requests for burial and memorials. Such letters may be very specific, including, for example, selections of music and readings, or the instructions may be of a more general nature.

Increasingly people are making plans with a funeral home, and such plans should be made readily available. Thus, including such information in the letter of last instructions will allow family and friends to proceed with the necessary arrangements following death. This letter can also direct the appropriate people to the location of the will and to those who have a copy of the will.

Legalities of Death

Laws change with the times; they attempt to catch up with technology, reconcile nondominant cultural beliefs and morals with the dominant paradigm, and find better ways to protect and control society. Laws, rules of conduct, ethics, religious beliefs, societal norms, cultural morality and expectations, community values, and personal meaning and attitudes all combine to work together to form a labyrinth of confusing and conflicting legalities. These rules and laws govern death in our lives from before conception to after death. Cultural beliefs, rules and laws intersect and modify, add, limit, protect, or confuse the issue at hand. There is no set rule, law, ethical position, or constant to assist in determining what the legalities of death are.

At the beginning of the 20th century, however, most people died at home, and the laws and rules of death were simpler and more attuned to the local cultures and customs. At the beginning of the 21st century, most people in North America die away from home, in hospitals and institutions. As living and dying have become much more complex in North American society, so have the laws and legalities of death.

Technology has surpassed our ability to develop legal rules to set standards governing death. It is difficult for anyone to die, in the normal course of events, without specific decisions being made to withhold or to withdraw medical treatment. Medical technology has trumped culture. The conflicting interests of specific cultures, family, community, and society at large—coupled with a general lack of knowledge of the laws relating to

death, and thus a lack of preparation for death—create a miasma around personal choice in death.

Technology allows babies, who in previous times would have died, to be born and to live long lives; technology can extend the *life* of a person for years beyond what the body alone could do. Definitions of death are no longer valid in the face of modern technology; a body does not have to live on its own. The law does not consistently inform as to who has the right to say when technology is to be released and to rely solely on the strength of the body to determine when death comes.

Definition of Death

The U.S. Federal Uniform Determination of Death Act provides two criteria for determining death: (1) irreversible cessation of circulatory and respiratory functions or (2) irreversible cessation of all functions of the entire brain including the brain stem. The ordinary definition of death is the permanent cessation of functioning of the organism as a whole. However, these definitions often do not provide the necessary explanation of death, and there exists still today legal, medical, ethical, moral, and religious debates over exactly when a person is dead. Sometimes the decision is made by the courts. Terri Schiavo, a married woman in Florida, who was in a persistent vegetative state and living on medical devices, was the subject of a court case, indeed a national debate, between the husband and the woman's parents, as to whether the medical devices should be shut down. The local court allowed the husband to make the decision to remove the medical devices that kept her breathing and her heart working and the woman died. Several states away and months later another woman was in a similar state. This time the parents of the woman and the husband agreed that the medical devices being used to keep their loved one alive were to be disconnected. The woman woke up and lives.

The "brain death" definition arose in the 1960s and 1970s as technology allowed the intensive care unit to become a surrogate for the brain stem to keep the heart and lungs functioning. For organ transplants, this definition of death, along with very advanced medical technology, allows time for the doctors to remove the organs for donation. In rare cases modern technology allows a fetus in a dead mother to proceed to term. If the brain is dead but the body is breathing and the heart beating, when do the doctors remove the functioning organs? Indeed, when is the body buried or cremated if cardiorespiratory functions are still active? Who will disconnect the medical devices?

When Does Life Begin?

The opposite end of the continuum brings even more legal complexities. The rule of law does not always control or satisfy the beliefs and rules of the various segments of society. The issue as to the moment life begins is argued vehemently by many and diverse groups. Some religions argue it begins at the moment of conception. The Supreme Court of the United States allows a woman to abort a child for many months after the point of conception. It is a contradiction in law and the rules of society. An abortion is permitted by law, yet in some states it is a crime to use illegal drugs while pregnant. If one kills a pregnant woman, the court may charge two murders. There is no one law or standard that declares when a forming fetus becomes a *life* and therefore has the right to the protection of the law. The law has much difficulty with the rights of a woman and the timing for the beginning of the rights of an unborn child. In this most contentious of debates, there is no satisfactory middle ground. The rules of secular law and religious belief can often collide with such a force, crushing any possible reasoned review of each individual case.

The Killing of Another

Both secular and religious laws prohibit the killing of another. The law makes certain exceptions: self-defense, defense of another, war, and the death penalty. Laws limit how each of these exceptions functions. Many jurisdictions do not allow the death penalty, and the rules of war must be obeyed to maintain the protection of the law. The use of deadly force in self-defense and in defense of another is strict and limited. The law recognizes degrees of culpability in the death of another, from negligence or wrongful death, to manslaughter, to the intentional killing of another. Penalties for wrongful killing range from civil monetary damages, to imprisonment, to death.

Wills, Trusts, and Probate

Wealth can be a burden at the end of life—for the person dealing with impending death as well as for the survivors—if arrangements were not previously made for a will or to avoid probate. The fear of death seems to prevent people from looking at these difficult end-of-life decisions and drawing up a will or an advance directive for health care. Wills and trusts can define how property is to be dealt with after death. The law will limit, in certain cases, the ability of the decedent to keep property from certain classes of people, such as a spouse. The rules of probate and estates are complex and as demanding on the courts as on the families. Inheritance is a creature of the statutes of the jurisdiction where the death occurs or where the matter is probated. Probate is the legal process by which the distribution of property and the protection of minor children are determined, whether through a will or by the statutes of the jurisdiction if there is no will. Advance planning can avoid the morass and expense of the probate court through the manner in which title is held to assets or by creating trusts. Whatever the situation is, the law of the jurisdiction controls the division and distribution of property. These rules are not consistent in all states or provinces. The laws of inheritance are often not consistent with the culture and customs of groups not part of the dominant society. This can create additional burdens on the courts and families. In a nonhomogeneous society the laws and statutes set down by the dominant culture will often clash with the beliefs and customs of nondominant cultures.

Advance Directives

Often the family and friends of the dying person sit helplessly at the bedside unable to navigate or control the vast medical system. Doctors make decisions that are often in conflict with the wishes of the family. A doctor's training is to protect and prolong life. Yet there comes a time to let go and allow the person to die as peacefully as possible. There are times when it is not in the best interests of the dying person to be resuscitated and placed on medical machines to prolong life. Often the family and the doctor or medical practitioner can come to agreement as to the form of care to be given. However, when the dying person can no longer speak for him- or herself, it becomes the task of the family and the medical personnel to decide how best to proceed. In the United States competent persons can make their own decisions as to health care at the end of life. Under the Patient Self-Determination Act of 1990, competent persons can control their medical treatment and even write an advance directive telling family and medical staff how they wish to be cared for when they can no longer make their own decisions. All hospitals are required to obtain such a document.

This is a sensitive subject in our death-phobic society. How, when, and under what circumstances this advance directive form is to be obtained are difficult issues for most people. It is a conversation that needs to take place within a family at a time when there is not a crisis.

Right to Die

In the United States it is a constitutional right to make one's own decision regarding medical care and to refuse medical care even if it will result in an earlier death. However, there is no correlative right to die. The U.S. Supreme Court refused to rule on the issue of assisted suicide, or euthanasia, and left it up to the individual states to decide how to deal with these issues. Only Oregon has a law allowing, under strict guidelines, a doctor to provide lethal drugs to end one's life. All other countries, save the Netherlands, have made assisted suicide or euthanasia a criminal offense. However, while assisted suicide is technically illegal in the Netherlands, doctors often assist patients in assisted suicide without any criminal prosecution. There are linguistic differences between the terms *assisted suicide* and *euthanasia*, wherein the former is usually thought of as having the consent of the dying patient, and the latter without such specific consent. Euthanasia under all circumstances is considered murder, even in cases of true compassion.

Disposal of the Body

While the laws in each jurisdiction are different regarding the handling of a body after death, generally a body must be buried in a cemetery or an authorized burial site. Cremations must be done by a licensed facility. In many jurisdictions the ashes of the deceased may be disposed of at sea

(not at the shoreline) or on private property with the consent of the property owner. Often a body may be kept at home for a certain period of time before the cremation or burial. Home funerals are difficult but there is a movement in some states, such as California, where the family can create their own funeral; the technicalities of the paperwork, however, often defeats the grieving family.

The legalities of death are confusing, vague, and inconsistent. Each jurisdiction forms its own set of laws and statutes. The customs of each culture and religion added to that mix often form a wall against understanding and resolution. One answer to chaos at the time of death is early planning and conversations with family members about how we wish to die. Completion of an advance directive and a will to direct the family and the courts can ease the burden of dealing with the legalities of death at the end of life.

Life Cycle and Death

Death is an integral and inevitable component of the life cycle and can occur at all developmental stages. Children and young adults may die, and older adults must die. Death at varying stages of the life cycle presents unique developmental and psychosocial challenges for the dying person and for his or her family. Medical and technological advances over the past century have changed the manner of death as well as the process of dying, leading to an increase in death anxiety and increased burdens on family caregivers. During an often prolonged dying process, the dying person and family members grieve multiple losses, including roles, hopes and dreams, material and emotional support. Finding meaning at the end of life can lead to lessened psychological distress for both the dying patient and for the patient's loved ones.

In 1900 the leading causes of death were accidents and infectious illnesses, which resulted in a relatively rapid dying process. Death most often occurred at home with all family members as active participants in caring for the deceased. In contrast, by 2001, 9 of the 10 leading causes of death were from chronic diseases with long deteriorating declines. The prolonged experience of dying in this century has given rise to changes in how care is delivered and who shoulders the burden of extended caregiving. Further, advanced technologies are prolonging the lives of children with congenital anomalies and chronic diseases. It is important to recognize that while the final stage of death may occur in a hospital, much of the prolonged dying process takes place at home. The meaning of the death and the nature of the loss, then, vary depending on the phase of the family life cycle.

The Family Life Cycle

Development, growth, and change are lifelong processes occurring in a sociocultural context. The family is the primary social vehicle for transmitting cultural worldviews and values. The death of a family member impacts the entire family as a functional unit, because all family members are interconnected and interdependent.

The awareness of the inevitability of death creates anxiety, as humans are wired for self-preservation. A shared cultural worldview that imbues life with order and predictability and provides rules and standards for behavior by which individuals attain a sense of value and self-worth alleviates the unconscious terror of annihilation. The family, as the primary mediator of culture,

organizes around the roles and rituals that support a worldview that death occurs at the end of a long, productive, meaningful life. How death is anticipated and experienced and mourned by the individual and the family is largely a function of whether it is consistent with or challenges this cultural worldview. In general, unanticipated and "unscheduled" deaths, deaths due to violence, deaths associated with multiple losses or other major stressful events, or deaths resulting in the loss of ongoing social support, result in less successful adaptation for surviving family members.

Death During Childhood

More than 50,000 children die in the United States each year. The U.S. infant mortality rate is higher than that of most Western European countries. The main causes of death during the first year of life are congenital abnormalities and sudden infant death syndrome. After the first year, the main cause is accidents, followed by cancer. A child's sudden death presents obviously different challenges for the family than does death following a long illness.

Approximately 25,000 children die each year from extended chronic illnesses. Another 500,000 children live with chronic, life-threatening illnesses. At the same time as they are dying, they are also growing and developing. Thus, to understand death during childhood, one must understand basic processes of child development: physical, cognitive, emotional, social, and spiritual. Cognitively, children's understanding of death depends on their developmental level. It is generally agreed that toddlers have little cognitive understanding of death. By middle childhood, most children have developed a mature understanding of death that integrates the concepts of irreversibility, nonfunctionality, universality, and causality.

Just as children develop more complex understandings of concepts as they get older, their psychosocial needs also change and are impacted by the dying process. The infant or toddler who is gravely ill, frequently hospitalized and separated from caregivers, and undergoing repeated painful medical procedures may be challenged to develop a sense of trust in their world. Preschoolers may find their need for independence and exploration limited by little or no energy, physical symptoms, and parental overprotection. School-age children may struggle with feelings of inferiority and inadequacy as their disease limits their interactions with peers and ability to engage in normal activities. The challenge for the family is clear: To promote healthy psychosocial development, parents must provide a continued presence and familiar routines and encourage the growing child to invest in age-appropriate activities to the extent their illness allows.

Children nearing the end of life are often aware of their impending demise and may grieve the loss of function, their inability to participate in play or school, and their imminent loss of family and friends. They may worry about how the family will cope after their death. While parents may wish to protect their children from the knowledge of their deaths, children will appreciate the opportunity for discussion in language they can understand. They may express their concerns indirectly, through symbolic or expressive interactions such as drawings, play, music, or rituals—and caregivers should be attuned to these important forms of communication. Even young children can be helped to find meaning and purpose in their short life and to receive reassurance that they will not be forgotten.

Indeed, the death of a child is one of the most stressful events in the family life cycle. An untimely, "unscheduled" death, it challenges the cultural worldview that children will outlive their parents, that the parents' role is to keep their children safe from harm, and that parents will live on through their children. The death of a child represents the loss of hopes and dreams for the future, and it challenges the belief in the orderliness and predictability of the universe. It often produces a crisis of meaning, as parents struggle to reconstruct a family narrative and find renewed purpose in the face of overwhelming grief. Prolonged grieving is common, and other important family roles (marital, parenting surviving children) are affected.

Surviving siblings often suffer a double loss: the loss of their sibling and the loss of support and emotional availability of their parents, who are coping with their own grief. A young sibling, experiencing typical rivalry or jealousy, may have wished for their sibling's death. Death can be described as a natural part of the life cycle, and the sibling should be reassured that their wishing for harm cannot make it happen. Children tend to

take euphemisms such as "passed away" or "gone to sleep" literally. Experts have thus found it to be more beneficial and less confusing to use words such as *death* or *dying* when explaining death to a child. The death of a sibling in childhood is a risk factor for later psychological difficulties. Much depends on the ability of parents to put their own grief aside to meet their surviving children's developmental needs.

Death in Adolescence and Young Adulthood

Motor vehicle accidents are the most common cause of death in adolescence, followed by homicide and suicide, but more than 3,000 teenagers die annually from chronic illnesses such as cancer, heart disease, metabolic disorders, and congenital abnormalities. Adolescents have a cognitive understanding of death equivalent to that of adults. Like adults, they are able to engage in spiritual and existential questions. Physically and psychosocially, many developmental changes occur in the years from age 11 to age 20.

Puberty may be delayed as a result of chronic illness, and illness and its management may cause disfiguring physical changes that are horrifying to a young person preoccupied with body image. The gradual shifting of attachment from parents to peers, and a developing sense of autonomy, may be delayed. The developmental push toward independence conflicts with the need for care during terminal illness. The terminally ill adolescent and his or her family may never celebrate the developmental milestones of a high school prom or graduation, a driver's license, or financial autonomy.

As adolescents deal with the sequential losses associated with terminal illness, they confront the meaning of their life and their curtailed future. Issues of transcendence and legacy may be prominent in their thinking. While minors are not considered competent to make medical decisions and decisions regarding end-of-life care, adolescents who have been undergoing medical procedures for long periods of time are often very knowledgeable regarding treatment, survival odds, and end-of-life options. Medical decisions may be the only manner in which terminally ill adolescents can assert independence and autonomy. There is an emerging consensus among pediatric health professionals, psychologists, and ethicists that adolescents have the functional capacity to make binding medical decisions, including the decision to discontinue life-sustaining treatment. These difficult decisions should, of course, be negotiated in the family context.

Parents anticipating the death of a terminally ill adolescent have the opportunity to express unconditional love and to complete unfinished business. Parents grieving an adolescent's sudden death, whether by accident or intentional violence, have no way to prepare for the massive disruption to life as they know it. While most bereaved parents feel guilty, the guilt is magnified for parents whose children have died by suicide or homicide. A search for meaning in the death may yield no good answers. For suddenly bereaved parents and siblings, grief is more likely to be traumatic and complicated, marked by anxiety and other mental health symptoms as well as sadness.

Young adults who receive a diagnosis of a terminal illness often face a long, protracted dying trajectory because, paradoxically, apart from the terminal illness, they are in otherwise good health, and illness complications like kidney failure or pneumonia are less likely to prove fatal. At the time of life when they are beginning a career and a family, they must prepare to die. Feeling cheated of the opportunity to see their children grow, young parents are faced with concerns of how to provide security for their family and how to leave a legacy for their children.

The death of a young parent and spouse has reverberations throughout the family. Multiple losses are likely to be experienced due to the loss of income and its effects. Like the death of a child, the death of a young adult is perceived as "off-time," a violation of the expectations of an orderly and just universe. Research shows that younger widows experience a more complicated grief than do older widows, for whom spousal death is expected. The grieving spouse must assume the role of both mother and father and must respond to his or her child's needs. Children may be angry at being abandoned by the dead parent. They may fear for their surviving parent's safety, for if the surviving parent dies, they wonder, "Who will take care of me?" Children may have to take on adult responsibilities if the surviving parent is unable to do so and may be loath to share their grief with their surviving parent, not wanting to distress the parent

further. Arguably the single most important factor in determining the child's adjustment to the death of a parent is how well the surviving parent is able to function, provide consistency and stability, and meet the child's developmental needs. Memories of the deceased parent often provide comfort to the bereaved child for years.

The death of a young adult also affects that adult's parents, whose relationship with their child has evolved from caregiving and total responsibility to a partnership and friendship with a unique individual. Parents continue their bonds with their dead adult children throughout the parents' life span.

Death in Middle Age

The main cause of death in middle age is sudden death due to stroke or heart attack. Overall, death rates in middle age have declined, largely due to progress in cancer treatment and prevention, and health promotion. While sudden deaths have the obvious advantage of preventing family members from experiencing or witnessing a long, painful decline and deterioration, no time is afforded to the family for shifting roles, learning new and needed skills, or anticipatory grieving. There is no opportunity to heal family rifts or make adequate financial preparations.

Families face multiple challenges when death follows long-term chronic illness. Families have had to reorganize to maintain "normal" family functioning during the long haul of the illness. As the illness progresses, families must continually adapt and roles must shift. Jobs may be lost as family members assume more of the caregiving burden, and the financial strains on the family are vast as savings are depleted. The dying adult must cope with the realization that long-held life goals and dreams may never be realized and will struggle to find new meaning and purpose in a shortened life span with diminished physical capacity. Bereaved middle-aged spouses often experience health impairment; men demonstrate greater impairment than women, possibly mediated by a greater loss of social support for widowers.

Death in Older Adulthood

The death of an older adult can represent, at the same time, the death of an individual, a spouse, a parent, and a grandparent in a complex web of family relationships across the life cycle.

Death in old age is a normative event. Nearly three fourths of all deaths in the United States are of people older than 65; one third of those are older than 85. Older adults have witnessed their friends and relatives die, and they are more accepting of their own inevitable death. They do not report declines in emotional well-being. The developmental task of older adulthood is to achieve a sense of integrity: that one's life has had meaning and value. Death is not fearsome for most older adults; rather, anxiety is centered on the dying process. Dying adults fear a loss of autonomy, and they fear burdening their family. They do not want to die alone, or in pain, or without dignity.

Death in old age usually occurs as a result of chronic conditions. There is likely to be a long period of caregiving at home resulting in tremendous financial, physical, and emotional strain on old and frail spouses and adult children. Bereavement often occurs as a transition from extended caregiving, and death may ease the burden and be seen as a relief. When familial resources are depleted, the end of life may occur in a nursing home or hospital, particularly when the patient has Alzheimer's disease or some other cognitive disability. In this case, death has come not too soon but too late.

The pattern of bereavement following spousal loss is varied. In general, older widowers have greater health and mental health risks than do widows. However, what is most striking is how resilient many older adults are following the death of their spouse. In one study, over half the bereaved spouses showed low levels of distress in response to the loss.

The grief of adult children following the death of their elderly parent tends to be attenuated, particularly if the parent died in a nursing home or had extended cognitive decline. However, if the adult child was actively involved in caregiving, there may be more emotional upset and symbolic connection to the deceased parent. Because the death of an elderly person is to be expected, there is often little social and cultural support for an adult child's extended bereavement. For young children, the death of a grandparent is often the first experience with loss. Not knowing how one is "supposed" to feel or behave, the children will take their emotional and behavioral cues from the

adults in their social environment. And the cycle of life, death, and bereavement continues.

Conclusion

The management of physical and psychological pain and suffering are salient issues for dying persons throughout the life cycle. Suffering can be eased when dying is viewed as part of the life experience. With palliative care, many patients can die at home, surrounded by loved ones. However, patients and families will need extended financial, material, and emotional support as they negotiate the inevitable role changes and transitions associated with a prolonged dying process. When death comes suddenly, it is the survivors who are faced with irreversible change and will need support. Much of this support can be provided by nonprofessional community members, but health and mental health providers have always had an important role in caring for people in transition. Nowhere is this more critical than in the transition from life to death, and from relative to bereaved.

Life Expectancy

Life expectancy for any given age may be defined as the average number of additional years of life persons of that age may expect to live, under the condition that the schedule of age-specific mortality rates prevails. Life expectancy is most frequently calculated and reported for persons at birth, that is, at age 0, but, as is shown in this entry, may be calculated for persons of any age. Information on the life expectancy for persons of a given age indicates how many years of life, on average, persons may expect to live if, during their lifetimes, they are subjected to the prevailing age-specific probabilities of dying.

Life Expectancy and the Life Table

Life expectancy is calculated via the life table, a mathematical table that presents the mortality experiences of a population. The life table dates to John Graunt (1620–1674). The life table starts with a population (a radix) of 100,000 at age 0; from each age to the next, the population is decremented according to age-specific mortality probabilities, until all members have died; the mortality schedule is fixed and does not change over the life of the population.

Table 1 is an abridged life table for U.S. females in the year of 2005, developed by the World Health Organization. Given the very different age-specific death rates and, therefore, age-specific probabilities of dying for females and males, life

tables are usually calculated separately for the two groups. Eight columns are shown in the table.

Column 1 refers to the age intervals of each group. The entries refer to the range of years between two birthdays. For example, the age group 5–9 refers to the 5-year interval between the 5th and the 10th birthdays.

Column 2 reports for each age group the age-specific death rates, designated as $_nM_x$. These are the only empirical data needed to build a life table.

Column 3 reports for each age group the probabilities of dying, designated as $_nq_x$. This is the most basic column of the life table; the probabilities are derived from the death rates in column 2. The column 3 data are the probabilities that persons who are alive at the beginning of an age interval will die during that age interval, before they reach the start of the next age interval.

Column 4 presents data on the number of people alive at the beginning of the age interval, designated as l_x. This column of data is calculated by subtracting the $_nd_x$ value (column 5) from the l_x value in the age interval immediately preceding the one being calculated.

Column 5 shows the number of people who die during a particular age interval, designated as $_nd_x$, and is determined by multiplying l_x by $_nq_x$.

Column 6 reports for each age interval the total number of years lived by all persons who enter that

age interval while in the age interval. The ${}_nL_x$ values are roughly given by the formula, ${}_nL_x = (l_x - \frac{1}{2}\,{}_nd_x)\,(n)$.

Column 7 reports the total number of years lived by the population in that age interval and in all subsequent age intervals, and is designated as T_x. To determine the values of T_x for each age interval, one sums the ${}_nL_x$ from the oldest age backward.

Column 8 presents the average number of years of life remaining at the beginning of the age interval, designated as e_x, and calculated by dividing column 7 by column 4. These are the life expectancy data.

Usually life expectancy for any given age, e_x, is larger than e_{x+n}, since e_{x+n} refers to additional life to be lived after the years $x + n$ have already been lived. However, Nathan Keyfitz and Wilhelm Flieger have found that in many countries (particularly developing countries and some developed countries), it turns out that e_1 is sometimes larger than e_0; this was the case in the United States as recently as the 1970s, when for females e_0 was 74.8 and e_1 was 75.2; life expectancy data for females in Mexico for the same year were 63.6 for e_0 and 66.9 for e_1. These patterns indicate a relatively higher infant mortality rate; they imply that if an infant is strong enough to survive the first year of life, then the average remaining lifetime on his or her first birthday is greater by more years than it was at the time of birth.

Life Expectancy and the Demographic and Epidemiological Transitions

Walter Scheidel reports that life expectancy at birth in ancient populations was in the range of 20 years to 30 years. In contrast, data from the Population Reference Bureau indicate that in 2007 the life expectancy at birth in the world was around 66 for males and 70 for females.

A major explanation for changes over time in mortality has its origins in demographic transition theory, which proposes four stages of mortality and fertility decline that occur in the process of societal modernization. The first stage is the preindustrialization era, with high birth and death rates along with stable growth. With the onset of industrialization and modernization, the society transitions to lower death rates, especially lower infant and maternal mortality, but maintains higher birthrates, so that rapid population growth is the result. The third stage is one of decreasing population growth due to lower birth and death rates, which lead then to the final stage of low and stable population growth.

Life expectancy changes may also be explained in terms of epidemiological transition theory. This theory focuses on the society-wide decline of infectious disease and the rise of chronic degenerative causes of death. According to epidemiological transition theory, as postulated by Abdel R. Omran, there are three stages. The first is the age of pestilence and famine in which the primary causes of mortality are influenza, pneumonia, smallpox, tuberculosis, and other related diseases, with high infant and childhood mortality and life expectancy averaging between 20 and 40 years. The second is the age of receding pandemics in which there is a decline in mortality due to improved sanitation, increases in standards of living and public health, resulting in a steady increase in life expectancy to around 30 to 50 years. The third stage is known as the era of degenerative and man-made diseases (heart disease, cancer, and stroke), in which mortality declines are due to medical advances in the prevention and treatment of infectious diseases. Richard G. Rogers and Robert Hackenberg have identified a fourth "hybristic stage," in which mortality is heavily influenced by individual behavior or lifestyle choices, and deaths are due to social pathologies such as accidents, alcoholism, suicide and homicide, as well as lifestyle issues such as smoking and diet.

Life Expectancy in the Contemporary World

Population Reference Bureau data indicate that in 2007 life expectation at birth in the world was 66 for males and 70 for females. In more-developed countries it was 73 and 80, and in less-developed countries (excluding China), 62 and 65. The highest life expectation at birth was in Japan (79 for males and 86 for females); the lowest was in Botswana (35 for males, 33 for females) and Swaziland (33 for males, 34 for females).

In general, the higher the country's level of economic development is, the higher its life expectation is for both males and females. The primary causes of death in more-developed countries are

heart disease and cancer, whereas in less-developed countries infant mortality and HIV are the leading causes of death. For example, Population Reference Bureau data for 2007 indicate that the infant mortality rate in Botswana was 56, in Lesotho 91, and in Swaziland 73, compared to less than 3 in Japan and Sweden. The percentage of people living with HIV between the ages of 15 and 49 in these countries is among the highest in the world. In 2007, the percentage in Botswana was 24.1, in Lesotho 23.2, and in Swaziland 25.9, whereas in Japan it was less than 0.1%.

Life Expectancy Differences by Sex

In more-developed countries, life expectancy at birth for females is approximately 5 to 7 years more than for males. This difference is attributed largely to biological and hormonal advantages that function as protective factors in women's health. However, this benefit is not always found for women in less-developed countries. For example, life expectancy in 2007 for males in Japan was 79 and 86 for females; in the United States it was 75 and 80, and in Western Europe, 77 and 83. In less-developed countries like Afghanistan, life expectancy is equal for both sexes: 42 years. In Botswana, life expectancy for women is in fact lower than for males (35 for males, 33 for females). Women in less-developed countries tend to have lower education and social status than males; these social disadvantages tend to obstruct the natural biological advantage that women have over men in life expectancy.

Life Expectancy Differences by Race and Minority Status

There are also life expectancy differences among racial and minority populations. In 2003, the life expectancy advantage for white females over black females in the United States was 4.4 years, and the advantage for white males over black males was 6.3 years. The racial differential in mortality in the United States has been studied and analyzed by medical and social scientists for many decades, but the differences have remained. A major reason for the racial differential is attributed to the socioeconomic consequences of lifelong poverty and experiences of racial discrimination, which limit the potential quantity and quality of health care available.

The Hispanic Paradox

Of particular interest in any analysis of majority–minority group differences in life expectancy is the consistent finding by Richard Rogers and his colleagues that Mexican Americans in the United States have an expectancy similar to, and sometimes higher than, Anglos (i.e., white non-Hispanics). Thus despite the fact that Mexican Americans and African Americans have higher rates of poverty and unemployment than do Anglos, and have also experienced more discrimination from the majority, Mexican Americans compared to Anglos are not disadvantaged with regard to life expectancy and other measures of longevity, but African Americans are. Several hypotheses have been offered to account for the Hispanic paradox and may be subsumed into three groups: data artifacts, migration effects, and cultural effects.

Life Expectancy in the Future

High levels of life expectation have been reached in this new century by many of the countries of the developed world. At issue is the likelihood that mortality rates will continue to fall, resulting in even higher levels of life expectation than those already attained. There are two positions: One argues for a limit and the other against.

An upper limit to human life expectancy is noted by James Fries, who predicted in 1980 that humans have a maximum potential life expectancy averaging about 85 years. Jay Olshansky and Bruce Carnes agree, noting also that all living organisms are subjected to a biological warranty period. If it is possible for humans to live to 100, people beyond age 80 should not be showing functional decline. But the data show substantial decline by age 80. Thus they contend that human life expectancy in the United States is not likely to exceed 90 years at any time in this century.

The major proponents on the other side, proclaiming the possibility of future and continued mortality declines, are James Carey and James Vaupel. They note that every time a maximum life expectancy number is published, it is soon surpassed. They also note that death rates in human and many nonhuman populations do not continue

to increase with increasing age, but there is a slowing or deceleration of mortality at the oldest ages.

Many of the developing countries still have high rates of infant mortality and general mortality. Infectious diseases remain a dominant cause of death in many of these countries. Modern medical and public health techniques will surely bring about further reductions in mortality from these causes, leading to declines in mortality in many countries.

Degenerative diseases are the major causes of death in the developed world. It is expected there will be future improvements in the treatment of these diseases in the next decades. However, only a basic breakthrough in the area of the physiological process of aging will increase substantially the length of time people in the developed world will live. Even the total elimination of a specific degenerative disease would not greatly increase life expectancy because, as Conrad Taeuber pointed out many years ago, if a cure is found for one degenerative disease, this will provide the opportunity for death to occur from another.

Life Insurance

The first reference to life insurance comes from the Middle Ages. Groups of the poor in Rome came together to bury members and help their surviving family. It became popular in England in the 1600s. In France, life insurance was forbidden by the Marine Ordinance of 1681 on the basis that human life could not be valued or traded. In 1787 the King's Council authorized the first life insurance company in France.

The first company in the United States was formed in 1735 to help the families of Presbyterian ministers in Philadelphia and New York. The first companies were mutual companies, owned by the policy members. Later companies were publicly owned stock companies. The United States still has a mixture of the two types of companies.

In the United States, life insurance became popular in the 1840s when companies started to aggressively market life insurance policies. Since people did not want to place a dollar value on loved ones' lives, policies were used for commercial interests. Policies were first used by creditors on the lives of people who owed them money in the Northeast and in the South on the lives of slaves. In addition, slaves' lives were also insured by fire insurance as property. Business still uses life insurance to protect against the loss of key personnel and to allow a partner to buy out the family of a deceased partner. By 1860 the industry was marketing policies to protect the family if the primary breadwinner died.

Due to lavish spending and lobbying in the late 1800s at the expense of policyholders, New York legislature formed the Armstrong committee and in 1907 enacted strict guidelines for the investment

and use of life insurance premiums. This legislation was later adopted in many other states. With the passage of the War Risk Insurance Act in 1914 the U.S. government started to offer *term* and disability insurance. In April 1917, it provided $4,500 term life insurance to active duty personnel and sold additional insurance to families who wanted more coverage. When the service men and women returned home this type of policy declined in favor of *whole life* insurance. By the time of the Great Depression over 120 million policies were in force, the equivalent of one for every man, woman, and child in the United States at that time.

Although life insurance has many uses in both business and family life, the main purpose of life insurance for families is to replace lost income to the family when a family member dies during his or working years. It is also used to cover final medical bills, funeral expenses, and estate taxes for families that do not have other assets to cover these expenses. Life insurance policies can be used to ensure that child support or spousal maintenance payments continue even if the spouse making the payments dies. In recent years, a new issue with life insurance, the viatical insurance payment, has been tapping into the death benefit by critically ill patients while they are still alive.

Parties to Life Insurance

The insured is the person on whose life the policy is based. When the insured dies, the death benefit or face value is paid. The owner is the person who pays the premiums and has access to the cash value. The premium is the amount due the insurance company to pay for the life insurance policy. The beneficiary is the person or entity (such as a charity) that will receive the death benefit when the insured dies. A contingent beneficiary is the person or entity that will receive the death benefit if the primary beneficiary dies before the insured. The insurer is the insurance company that collects the premiums and pays the death benefit.

Types of Life Insurance Policies

There are three basic types of life insurance: term, whole life, and universal life. Term insurance is basic life insurance. It pays a death benefit to the beneficiary if the insured dies within the term of the policy. The term can be between 1 and 30 years. There is no cash value to this type of policy. For most types of term insurance policies, the premiums will increase each year.

Annual renewable term is a term policy that is renewed each year. The insured will only need to visit the doctor the first year, as the policy has a guaranteed renewable clause so that it can be renewed without proof of insurability if the owner wants to keep the policy for another year. Level term is a term policy under which the premium stays the same for the term of the policy. The premium is figured by taking an average of the premiums over the life of the policy. Group term is a policy that is purchased through or provided by one's employer, organization, or other group. The group is the owner of the policy, and the employee or member is the insured. This is the most inexpensive way to purchase life insurance but the insured may lose the coverage if the insured leaves the employer or the organization. Convertible term is a term policy that can be switched to a whole life or universal life policy at a later date. Perhaps the owner can only afford term insurance at the moment but is worried about the rising costs in later years. When the policy is converted, the owner locks in the premium.

Whole life insurance pays the death benefit as long as the premiums are paid, although some policies end at age 99. The amount of the death benefit cannot be changed. The premium remains constant for the life of the policy. Unlike term insurance, whole life insurance has a cash value account, or the saving component. The earnings on this account accumulate income tax free. The owner only gets the cash value if the policy is surrendered. The beneficiary gets the death benefit when the insured dies.

With each premium payment, the amount left after paying for the death benefit and administrative costs is held in an account, which pays either a fixed or variable return. The types of return depend on the type of policy. *Fixed* means the owner has a guaranteed rate. The insurance company chooses how the money is invested, usually in highly rated bonds and mortgages, and the rate will be based on current rates when the policy is purchased. *Variable* means there is a low guaranteed rate and if the company's investments do better than expected they will add additional income to the account for that period.

For a fee the owner can borrow against the cash value. Any unpaid loans will de deducted from the cash value, if the policy is surrendered, or from the death benefit, if the insured dies.

Universal life insurance is similar to, but more flexible than, whole life. It allows the owner to raise or lower the amount of life insurance as family needs change. With some policies the owner can pay one large amount and then future premiums are paid for out of the cash value. With other policies, the owner may have a minimum that has to be paid and an upper limit, which is the maximum the owner may choose to pay. This allows the owner to vary the premium rather than taking out a loan, saving fees and interest charges. There is also a loan option available to the owner.

Policies can have a fixed rate of return on the cash value or a variable rate of return. In addition, some policies allow a choice of investments offered by the company. This type of policy does not have a guaranteed amount, and the owner accepts all the risk for the investment decisions.

There are two types of universal life insurance. The level option works like whole life insurance, with either the cash value or the death benefit being paid but not both. The increasing option allows the beneficiaries to receive both the cash value and the death benefit.

Life Insurance Needs

The amount of life insurance needed depends on the expenses to be covered when the insured dies, such as debt, money for children's college expenses, child care costs, living costs for a spouse or minor children, final medical bills, funeral expenses, and estate taxes. However, a major consideration in how much life insurance to purchase is how much the owner can afford. While fully funding expenses makes life easier for the survivors, the owner needs to be able to comfortably pay the premiums to keep the policy coverage in force so that the money is available when the insured dies.

It is important to review life insurance polices whenever life events such as births, deaths, marriage, and divorce occur. These events may influence the amount of coverage needed as well as the choice of beneficiaries and contingent beneficiaries.

Payout Options

There are many different options beneficiaries can choose to receive the death benefit. The simplest payout option is a lump sum that pays beneficiaries the death benefit of the policy in one payment. They receive the money income tax free.

With the interest-only option, the death benefit is invested with the insurance company. Beneficiaries only receive the earnings. At some later date the death benefit is paid to the beneficiaries or contingent beneficiaries. The income is taxable as to the beneficiaries.

The other type of payout is an annuity, or a series of payments. Part of the payment will be tax free as a return of the death benefit, and part will be earnings on the money remaining with the insurance company, which are taxable.

There are two types of annuities that pay benefits over the life of one or more beneficiaries. A life income annuity pays the payment for the life of one beneficiary. When that beneficiary dies, the payments stop. A joint and last survivor income annuity pays the same or lesser payment over the life of two or more beneficiaries. The amount of the payment will be less than with a life income annuity, as the insurance company will probably have to make the payments for a longer amount of time.

Some annuities only pay for a certain period of time or a specific amount. A period certain annuity pays the payment for a specific number of years. This option can also be combined with the life income option. A specific income annuity pays the beneficiaries a specified amount until the death benefit and any earnings have been paid out.

While the beneficiary receives the death benefit without paying any income tax, the owner's estate may have to include the death benefit or the cash value as an asset when figuring estate taxes. If the owner and the insured are the same person, the death benefit will be included in the owner's estate for estate tax purposes even if the beneficiary is someone else. If the owner and the insured are different people, then the cash value is included in the owner's estate for estate tax purposes if the owner dies before the insured.

Life Insurance Fraud

Insurance fraud occurs when individuals deceive an insurance company or agent to collect money that they are not entitled to, or when insurers or agents engage in deceptive practices that have negative effects for consumers. Life insurance is a contract between an individual (policy owner), and the insurer, who agrees to pay a sum of money upon the insured individual's death or other event, such as terminal or critical illness. In return, the policy owner agrees to pay a specific amount at regular intervals, called a *premium*, or in lump sums. The person designated to receive the proceeds from the life insurance policy is called the *beneficiary*. Life insurance policies are often set up to cover the policyholder's bills and death expenses. In the United States, the most common form of life insurance specifies a lump sum to be paid upon the death of the policy owner. This entry describes life insurance fraud, discusses fraud by individuals as well as by agents and insurers, and ends with information on factors related to life insurance fraud.

Life insurance policies require the beneficiary of a policy to provide due proof of death when making a death benefit claim in support of which the beneficiary must submit a certified copy of the deceased's death certificate. A complete signed copy of the insurer's claim form is also required. Proceeds from life insurance policies may be paid as a lump sum or as an annuity, in which the funds are paid over time in regularly recurring payments for a specified period. If the insured's death is suspicious and the policy payout is large, an investigation of the manner of death will be conducted prior to the claim being paid. When a policyholder disappears without a trace and there is no direct evidence of the manner or fact of the insured's death, the claim may not be honored because so many such claims are fraudulent. In such cases, courts frequently allow the use of circumstantial evidence where the age of the insured would be beyond human expectation, where the insured's health was seriously impaired upon his or her disappearance, where the insured was exposed to danger or peril, and where the insured's absence is unexplained and evidence shows that the insured's character and habits are inconsistent with voluntary absence for the period involved.

Insurance fraud represents a major criminal activity in the United States. Fraudulent life insurance claims, estimated as high as $9.6 billion each year in the United States alone, are cause for the high cost of insurance that is absorbed by the consumer. One study conducted during the late 1990s examined 349 life insurance companies which, at the time, represented more than 93% of the U.S. life insurance market. The study authors reported that urban areas have higher rates of life insurance fraud and fraudulent claims and these claims are greatest in those regions of the country where people appear to accept such fraud as a way of life, where the unemployment rate is high, and where the economy is less than robust. The extent of existing laws does not appear to be a factor in the prevalence of fraudulent life insurance claims. Income and the existence of fraud penalties and punitive damage laws were not found to be related to the suspected fraud reported for each state. This same study reported that of 7,596 contested life insurance claims, only 43 had fraud listed as the reason for a denial of the claim. However, the majority of other reasons cited can be interpreted as fraudulent.

Life insurance policies include incontestability clauses, limiting the time an insurer has to contest the validity of an insurance policy based on material misrepresentations made by the policyholder during the application process (Alonso, 2006).

States began to require that life insurance policies include these clauses in the early 1900s. Claims related to fraudulent misrepresentation fall within these terms, so a claim that a policy is not enforceable due to fraudulent misrepresentation must be made within that limited period. The legislation behind such clauses serves to protect beneficiaries from insurers who may refuse to honor policies, minimizing costly litigation.

Life Insurance Fraud by Consumers

Consumers commit two types of insurance fraud, namely, hard fraud and soft fraud. Hard life insurance fraud involves an individual or group faking a death to collect on the life insurance policy. Soft life insurance fraud involves the documentation of inaccurate information submitted to the insurance company on applications or other documents.

Individuals sometimes purchase life insurance for themselves and then fake their death to collect on the insurance proceeds. Most of these individuals travel to another country and support their death claim with fraudulent documents, but very few are successful because insurance companies generally investigate all foreign death claims. For example, claimants dug up a recently buried body and staged an accident, after which one of the individuals claimed the "accident victim" to be the policyholder. After burial, the beneficiary filed a life insurance claim. When such fraud is uncovered, criminal charges filed lead to prison sentences.

In some cases, individuals purchase life insurance policies for other individuals and then attempt to collect on the insurance proceeds upon claiming that individual to have died. In some cases, the person reported to have died has no idea that another is filing such a claim, whereas in other cases there is collaboration between individuals to defraud the insurance company. There have also been instances in which individuals purchased life insurance policies on a spouse or child, or even an animal, murdered that individual, and attempted to collect on the life insurance policy proceeds. In the early 1900s in England, there was a rash of child homicides committed for gain through life insurance fraud following a ruling that coroners could not inquire into the death of a child. The ruling was quickly rescinded, thereby allowing coroners to investigate all sudden, unexpected deaths.

Life insurance fraud also occurs as a result of suspicious or questionable actions by the applicant or policyholder, such as misrepresenting health status or applying at a suspicious time in relation to the insured's death. One type of fraud occurs when individuals with a life-threatening illness apply for a new life insurance policy without disclosing the truth about their health. Cases have also been documented in which individuals open life insurance policies on family members but have healthy individuals submit to the medical examination in place of the actual family member who is in poor health.

Another type of life insurance fraud occurs when individuals who are healthy indicate that they are terminally ill in order to viaticate a life insurance policy, receiving a viatical settlement, or a percentage of the face value of the contract. A viatical settlement is the discounted, predeath sale of an existing life insurance policy when the insured is known to have a terminal condition. Viatical settlement fraud occurs when misrepresentations are made on insurance policy applications, concealing the fact that the applicant has already been diagnosed with a terminal condition. Fraud also occurs when misrepresentations are made to viatical settlement investors by the viatical companies regarding the life expectancies of the insured or guaranteed high rates of return.

Life Insurance Fraud by Agents or Insurers

The elderly are often victimized by unscrupulous insurance agents who sell policies that do not actually exist. The victim pays the premiums based on the belief that a policy exists, but no money is paid upon their death, as the policy was fraudulent. An insurance agent can sell fake coverage from a nonexistent insurance company, or can sell fake coverage under the name of a legitimate company. The individuals who believe they are purchasing a life insurance policy may receive an official-looking policy or proof of coverage that is worthless.

Yet another form of life insurance fraud occurs when agents pocket the applicant's premiums rather than forwarding the fee to the insurer. Again, the applicant believes an insurance policy has been issued, but the policy is in fact not current and is, therefore, invalid. Finally, life insurance fraud occurs when insurance company insiders

embezzle company funds, leaving no or very little money to be paid out to policyholders.

Sliding, Churning, and Twisting

Many individuals are victimized by insurance agents who sell overly expensive or unnecessary coverage or may even be covered in an existing policy. Known as "sliding," this activity occurs when an agent sells extra coverage that was not requested, but the individual pays for the extra coverage without knowledge that the payment is based on a separate, unsolicited policy. Examples of such policies are motor club memberships, accidental death coverage, and guaranteed renewable life insurance.

"Churning" occurs when deceitful agents, with the purpose of receiving a commission, convince individuals to use the built-up value of their current whole life insurance policy to buy a "superior" policy even though the existing life insurance coverage is sufficient. The victims spend their built-up cash value and must start building the cash value associated with the new plan all over again.

"Twisting," which is similar to churning, occurs when an agent urges an individual to change policies prematurely without being forthright about the negative aspects of changing policies. Individuals with a preexisting illness or other medical condition, for example, may not have coverage under a new policy.

Factors Related to Life Insurance Fraud

A catastrophe often leads to a large number of fraudulent claims; life insurance claims are filed for people who are stated to have died in the catastrophe but are actually still alive. Following the attacks on the World Trade Center on September 11, 2001, and the tragedy of Hurricane Katrina on August 29, 2005, many individuals filed fraudulent life insurance policies, claiming that family members died during such tragedies. Some individuals who filed such fraudulent claims were sentenced to federal prison terms after investigations had revealed the individual stated to have died was actually alive.

At the end of 2007, the Federal Bureau of Investigation (FBI) was investigating 529 cases of financial crime, with 209 of those cases being related to insurance fraud. The FBI expects the number of fraudulent claims to increase after several recent natural catastrophes. Soldiers also are at risk of fraudulent life insurance policies, as deceptive salesman attempt to sell policies that contain restrictive clauses that limit the payment should a soldier be killed or injured in the line of duty.

Most insurance companies have strict policies to prevent fraud, but some companies pay suspicious claims too easily. Indicators of life insurance fraud by applicants, policyholders, or third party claimants are as follows: The death of the insured occurred shortly after the policy's inception; the claimant had several small policies, often requiring no physical exam; evidence is found of financial distress directly prior to death; recent changes in coverage were made, generally in increments not requiring physical exams; recent changes in beneficiaries were made; the insured was involved in an activity not considered customary for the individual when he or she died; the body of the stated insured is never found, or identification is incomplete due to the condition of the deceased; and the coverage amount does not coincide with the insured's income or estimated net worth.

Life Review

Life review refers to reminiscence in revisiting and evaluating one's life experiences, often at the end of life. Life review has been described as the relatively systematic reflection upon one's life and personal history. Like a story, life review encompasses an assessment of life's vicissitudes with all of its triumphs, successes, and failures, of life's twists and turns. The life review process is commonly used by professionals in conjunction with the dying elderly, but it is utilized in a range of settings. The concept has broad appeal because a specific therapeutic approach or discipline is not required.

For the dying, life review affords an opportunity to take the listener to where the dying person needs to go, to revisit the past. Often this means embarking on a series of painful experiences that did not turn out well. As reviewers have an opportunity to revisit and thereby reprocess part of life, they often develop new insights, allowing them to redefine if not accept a life event they must learn to integrate into whatever time they have remaining. It is through life review that individuals find that their life has meaning.

Developmentally life review facilitates the final psychosocial life stage, "integrity," as described by Erik Erikson, who proposed all individuals accept life as it is lived with no substitutions. In so doing, a person experiences integrity rather than despair.

A critical component of life review is the relationship established between the reviewer and the listener or any individual who commits to being interested in the reviewer and communicates that interest to increase interpersonal rapport. Life review occurs when trust is established in that relationship. It requires a secure environment and a caring relationship to facilitate the sharing of private thoughts and life events that are viewed in a negative context. Successful life review is based on acceptance without judgment. Although the listener may hear expressions that are difficult to accept or understand, and be exposed to issues that are contrary to their personal values, it is important the listener maintain a neutral posture lest the negative nature and feelings of the past event be reinforced in the speaker.

Intended to benefit the reviewer, the experience can also benefit family members. But life review is not intended to resolve family conflicts. It is also true that the reviewer may desire to share with someone outside the circle of family and friends. Described as the "stranger sitting on the airplane phenomenon," there is therapeutic value when the stranger leaves, taking all the secrets with him or her.

It is not uncommon for the review to be presented in a harsh manner. Thus, one skill important for the listener to develop is "reframing," allowing the reviewer to move to a new understanding of past events while evaluating the past in a balanced context.

A variation in life review is useful for enlarging the family's oral history. These methods include writing, audiotapes, and videotapes. Music, home videos, pictures, and treasured mementos also are useful for stimulating the telling of stories. They are natural connectors to a variety of times and places in their lives.

Life review is accomplished through formal and informal techniques in end-of-life care. Formal techniques include the "psychosocial history" to identify important life events, which can be transferred to a "psychosocial plan of care," a living document prominent in hospice care. An informal tool used for life review is known as "Reminiscence: Process and Outcomes." This is an effective tool that walks the listener through an overview of life review that is user friendly and demonstrates how life review can be broken down and simplified.

Some research findings suggest that life review is associated with reduced depression, improved memory, enhanced self-esteem, and improved ego integrity and social well-being. The potential benefits for developing life review skills will become more apparent as the baby boomers continue to age and are faced with the challenge of finding "integrity" rather than despair in their golden years.

Life Support Systems and Life-Extending Technologies

More than other technologies, life support systems and life-extending technologies symbolize the ethos of modern medicine to defy death or at least postpone it. Life support systems provide a partial or total substitution of major bodily organs and functions, while life extension technologies seek to increase one's maximum or average life span by improving and upgrading those functions.

Life Support Systems

Life support systems are therapeutic innovations—biochemical and technological—that substitute and support vital bodily functions such as respiratory and cardiac function, blood circulation, bodily temperature regulation, detoxification and filtering (i.e., replacement of kidney function), immunity function, nourishment and hydration, sometimes for long periods of time.

The Intensive Care Unit

The intensive care unit (ICU) is a highly specialized life-support environment coordinating the provision of constant monitoring and support of vital body functions. The purpose of ICU units is to "resuscitate" and maintain critically ill patients alive, not to cure the underlying disease. Even if organized efforts to resuscitate and ventilate people date from 1769 with the Society of Resuscitation of Drowned Persons, in England, the conception of the ICU as a life support environment was not realized until 1953 in Copenhagen. Regular life support technologies in the ICUs and emergency units are defibrillation for cardiopulmonary resuscitation (CPR), mechanical ventilation, heart/lung bypass, dialysis, intravenous drips, vasopressures (e.g., adrenaline) and antibiotics, bodily temperature control, and intubation for total parenteral and enteral hydration and nutrition.

CPR consists in the restoration of breathing and heart function. CPR as first aid is a simple "mouth-to-mouth respiration" technique to supply air to the lungs, and rhythmic chest compressions to maintain circulation and the oxygen supply to the brain and other vital organs until more advanced life support such as defibrillation can be provided. In defibrillation a low electrical shock is delivered to the heart with an automated external defibrillator until the normal sinus rhythm of the heart is restored. Advanced cardiopulmonary resuscitation in addition to defibrillation includes mechanical ventilation (assisted breathing), anti-arrhythmic drugs, vasopressures (drugs to stimulate circulation such as adrenaline) and postresuscitation care.

Mechanical ventilation—that is, the substitution of respiratory function by a ventilator, an external device pumping air and oxygen in and out of the lung—provides the most emblematic image of life support. A first breakthrough in assisted ventilation was the iron lung—an airtight coffin-like box that enclosed the body of the patient keeping the head outside and rhythmically pressured and

de-pressured the chest forcing air into the nose and lungs. The iron lung was devised to rescue victims of the polio epidemic of 1920s (poliomyelitis was a viral infection that destroyed nerve substance and led to temporary or permanent paralysis—including respiratory paralysis and ultimately death).

Another major turn took place during the next polio epidemic in 1952, when Danish anesthesiologist Bjorn Ibsen discovered the principle of the modern ventilator as a better alternative to the iron lung. The air was to be supplied via *intubation:* a tube (endotracheal tube) placed in the airway passage (mouth or nose) or directly into the trachea through a small surgical incision.

Pacemakers, Implantable Cardioverter-Defibrillators, Left Ventricular Assist Devices, Artificial Hearts

Pacemakers and implantable cardioverter defibrillators (implantable medical devices developed to correct cardiac rhythm disturbances) and ventricular assist devices are mechanical blood pumps that replace part or the entirety of the heart's function and are utilized to bridge heart function during heart transplants. The total artificial heart is an implantable mechanical device still under development but being used to alleviate and increase the short-term survival of patients with end-stage heart failure (e.g., patients waiting for a heart transplant).

Dialysis

Dialysis is the process of removing salts and impurities from the blood, a process normally performed by the kidneys. If the kidney fails to perform this function, the result will be death within a few days. Dialysis is carried out as *peritoneal dialysis* (via the intestine) or as *hemodialysis* (via a shunt or in the arm), and during several hours blood is taken, filtered, and returned to the patient's body. Dialysis is the only alternative to kidney transplantation in managing acute renal failure (e.g., resulting from poisoning) or chronic renal failure (e.g., resulting from hypertension or diabetes).

Life-Sustaining Antibiotic Therapy

Antibiotics are first-line tools in the control of life-threatening systemic bacterial infections in emergency services, such as acute bacterial meningitis, pneumonia, septic shock, tuberculosis, or secondary infections in HIV/AIDS. Recent studies suggest that known antibiotics may not be highly effective in the future due to the spread of super-resistant bacteria.

Enteral and total parenteral nutritional support and hydration are used for patients unable (or unwilling) to swallow or digest food or fluids taken by mouth; these patients risk dehydration, malnutrition, and eventually death. The two methods of providing artificial nourishment and fluids are enteral nutrition, in which a nutritional "formula" is delivered trough a feeding tube into the nose, mouth, or surgical opening into the digestive tract, and total parenteral nutrition, in which nutrients are supplied intravenously via a catheter directly into the bloodstream.

Ethical, Social, and Legal Issues in Life Support

The availability and utilization of life support seems to sustain the notion that if we have the technological means to "save lives," we are duty-bound to utilize them. Life support has truly saved lives to an extraordinary extent, yet these technologies bring about the unexpected side effects of prolonged lives (in many cases, with serious impairments and disabilities), and prolonged death processes. Such side effects have garnered mass media attention and public debates about the right of patients to refuse life support, the sanctity of life, and the medical obligation to save lives. Cases such as Nancy Cruzan, Karen Quinlan, and Terri Schiavo in the United States are indicative of these controversies. Other issues raised by the success of life support interventions are elevated costs to health care systems. In the United States in particular, where thousands of people are uninsured, the cost of life support technologies are debated.

Life-Extending Technologies

While life support focuses on salvaging life and sustaining vital functions in crisis situations, life-extending technologies aim to minimize and even cancel the detrimental impact of the environment on human cells and tissues, reducing the rate of aging at the cellular level. Some of the same technologies used for life support are also used for life

extension: dialysis, organ transplantation, insertion of pacemakers, implantable cardioverter-defibrillators, left ventricular assist devices, continuous chemical and antibiotic therapy, and nutritional support. In addition there are a variety of "therapies" and practices relating to healthier lifestyles, including exercise, diet and nutrition, as well as the use of a wide range of medicines and medical therapies. These therapies include:

Caloric Restriction

Several animal studies indicate that a 40% caloric restriction extends the life span almost by 50%, lowering free radicals and oxidation damage. However, even a milder caloric restriction of 20% will activate *sirtuin,* a protein responsible for neutralizing aging. Sirtuin is also activated by *resveratrol* (found in grape seeds and red wine) and by exercise.

Bodily Exercise

For some decades there has been growing awareness of the value of regular physical activity for good health and longevity. A variety of guidelines, programs, and styles have been developed. Particularly noteworthy is the engagements of older persons in exercise, both aerobic and brain exercise. There is evidence of substantial preventive value in exercise against the primary and secondary prevention of cardiovascular disease, cancer, diabetes, rheumatism, and neurological disease, for example.

Supplements and Antioxidants

Supplements and antioxidants such as vitamins, minerals, enzymes and other substances can be understood as marketed technologies directed at preventing aging.

As we age, our brains age too, conveying an increased risk of neurological diseases such as Alzheimer's disease. Aspirin, B and E vitamins, the extract of the plant ginkgo biloba, green tea, and coffee seem to prevent "brain aging" by reducing inflammation and oxidative stress in brain tissue. Vitamin-like substances like omega-3, phosphatidylserine, carnitine, lycopene, cinnamon, turmeric, red pepper, lutein in green vegetables, and quercetin in onions and garlic are also recommended for a life extension diet.

Antioxidants also play an important role. Most of the oxygen we inhale is transformed into energy by the mitochondria (mitochondria are body cells responsible for the generation of energy and essential components of metabolism), but some it turns into oxidants damaging the cells. Common antioxidants are vitamins A, C, and E; selenium; and melatonin (a hormone produced by the pituitary gland). Enzymes such as glutathione, coenzyme Q10, alpha-lipoic acid, and superoxide dismutase also protect the cells from damage from free radicals.

Hormone Replacement Therapy

Several hormones decline with age. For example, low levels of DHEA (dehydroepiandrosterone sulfate; a hormone produced by the adrenal glands), human growth hormone, and testosterone correlate with degenerative diseases and autoimmune disorders. Whereas some studies have shown that steroid replacements improve several functions in elderly patients, others have yielded contradictory findings and complex side effects.

Biotechnological Approaches to Life Extension

Biotechnological interventions focus on the replacement of damaged organs and, alternatively, on replacements at cellular and DNA level.

One proposed solution to aging is the replacement of damaged organs with natural clones, or artificial organs manufactured in some durable material. Yet, organ replacement cannot be an optimal solution to aging, as the key to restore aging is to operate at molecular level, replacing and repairing damaged cells with therapeutic cloning, nanotechnology, or by modifying the genetic program to prevent the aging process. *Therapeutic cloning* uses stem cells to replace damaged cells. Stem cells are undifferentiated cells that have the potential to become any type of cell in the body and that produce telomerase, an enzyme that rejuvenates the cell extending the number of times it can divide, almost indefinitely. These cells can be grown, genetically modified, and then implanted in the body to replenish older cells. *Gene therapy* consists in the manipulation of genes associated with aging. Gene therapy research has managed to significantly extend the life span in worms and mice. *Nanotechnology* aims at building minuscule robots to go into the cell and

reverse age-related damages, a promising but still theoretical strategy.

Ethical, Social, and Legal Issues of Life Extension

Human life expectancy has increased twofold in the past century, due to better social, biomedical, sanitary, and dietary conditions, and as a result of decline in infant mortality. The maximum human life span, however, has not increased at the same rate. Few individuals live to be 100 years (although there many individuals older than 100 years in Japan, and this population is expanding at more than 5% per year).

Aging is no longer defined as a natural decay, but rather as a failure in the mechanisms of maintenance and repair at a biochemical level. After a certain number of replications, the process of cell division declines and finally ceases. The accumulation of molecular damage in the cells triggers diseases associated with aging, such as atherosclerosis, cardiovascular diseases, dementia, and cancers, among others.

While interventions in lifestyle and nutrition generally aim at increasing life expectancy, radical life extension proposes to develop biotechnological interventions to revert cellular damage, increasing the maximum life span to 130 years or more. Proponents of this perspective even foresee an indefinite postponement of aging.

The radical life-extension program has raised much debate around the possible consequences of living really long lives. Opponents to these attempts argue that radical life extension is unnatural and to a sense immoral; that extreme long lives would lead to overpopulation and that life extension would probably become a prerogative of wealthy elites. Proponents argue that diseases too are natural, and that this does not make them good. Moreover, preventing the onset of age-related diseases by intervening in the basic process of aging is the best way to improve the quality of human life. Many of these debates are highly speculative and theoretical. But, for the first time, research in radical life extension, by intervening in the senescence process, makes the possibility of postponing death a realistic and extraordinary prospect.

Literary Depictions of Death

Although death is a prominent theme in literature from the most ancient times to the present, it has always been depicted in connection with other themes. Scholars of the past century noticed that death was the source of most myths. In fact, symbolic or imaginative representations of death are found in some form in every culture, first as a revelation, then as a sacred tradition and finally as an exemplary model. Thus, the theme of death goes hand in hand with the evolution of literature, both in oral and written practices, and including all genres and species.

In the history of collective attitudes about death, it was thought that death representations were

mirrored by the extant societies and the successive epochs. Yet, figures of death may be totally contextualized; they spring from our own imagination. Consequently, death is difficult to define as an object; we can only conceive it as metaphor, allegory, dislocation, allusion, or play on words. This entry briefly reviews the historical background of the literary depictions of death. It then focuses on how literature helps us understand death as a human experience and as a pretext for writing. Finally, it examines modern approaches to death in the field of literary criticism.

How Common Understanding of Death Affected Literature

Ancient literature focused on the cult of the dead through epic poems, songs, and tragic plays. Medieval life, and thus its literature, was driven by war with death depicted either as a vision of horror or of heroism, depending on authors' goal to condemn or to praise war as a means to write history. In Dante Alighieri's *Divine Comedy,* the Arabian motif of the trip into the other world becomes central. It is filtered through Christian ideals as an allegory of the different states of mind that a person can experience. Thus, Inferno stands for evil and vice; Paradise is the image of good and virtue, and Purgatory is the transition between the two by means of repentance and expiation.

The Renaissance period, with William Shakespeare as the most representative figure, revived tragic stories of Greek antiquity and refurbished them in a way that put together love and death, bringing the tragic to paroxysm. French classicism continued the tradition of what scholars called "the theater of great passions," although with a sense of property and civil responsibility. The legendary characters such as Medea, Phaedra, and Iphigenia were no longer marionettes in the gods' hands, but victims of their own passions.

Seventeenth-century English Puritanism considered death by imagining the life beyond. John Milton's *Paradise Lost* is a transcription of the biblical myth as an allegory of the puritans' struggle against absolutism and aristocracy. However, after the publication of the *Encyclopédie* in France in the 18th century, the preoccupation with life after death was condemned as a form of putting down life on earth.

At the same time in England, the black novel was born, with its terrifying, gothic depictions of haunted castles, which have since inspired modern thrillers. Obsession with death was already a preromantic theme with the so-called poets of the dark, to whom the effusion of the mourning and the attraction of the tomb were constant sources of meditation. Cemetery wandering, vampirism, melancholia, and predilection with suicide were preferred literary themes during the 19th-century periods of Romanticism, Parnassianism, and Symbolism, which were followed by existential questioning upon "le mal du siècle" during the 20th century. The shocking experiences of the past century marked literature with grave accents of pessimism and nihilism. Themes of collective death (plague, genocide) and suicide promoted the idea of the absurdity of life and the belief that human destiny was mere chance.

Later Influences on Literature

Literary themes tend to follow the realities of the epoch. For Victorian writers during the Industrial Revolution, the theme of child death was very prominent, involving Christian strategies of consolation. Medical progress also impacted literature—in naturalist theory, the onset of death was no longer a punishment, but a consequence of the progressive disintegration of the organism.

Eventually, the theme of the apocalypse, or end of the world, gained in popularity. Thus, science fiction explored the territories of the imaginary through the depiction of cosmic dangers, biological disasters, or man-made disasters such as widespread nuclear war. Whether these literary trends inherit from the biblical myth of the apocalypse or announce the ecological movement, anxiety grew with the representation of nothingness. Scholars said that the theme of the end of the world is as old as the fear of dying. However, literature has always managed to surprise contemporaries as did J. B. Cousin de Grainville's tale of the last man on earth. He imagined the possibility of the human species becoming sterile around the same time Malthusian theory emerged. In de Grainville's novel, to prevent mankind repeating the same wars and horrors, Omégare chooses not to go and meet the last woman on earth.

Death as a Human Experience

Both poets and writers have been inspired to write about death. Writing about the death of others implies a testimonial function of literature while the reference to the self is merely fantasy and imagination. However, scholars figured out that writing of the death of others means mastering the fears and anxiety related to the death of self.

The Other's Death

The literature that developed around the other's death attempted to explain the causes of death through crime, war, natural disasters, and, very late in the 19th century, organic decomposition. The accent was on the survivors and their mourning, bereavement, and grief, either in a psychological dimension or in a ritual one. Literature praising the dead emerges from the ritual, but it has also the mental function of the duty that the living have to the dead. What comes after death is not found in science, allowing fiction free rein. Literature about life after death embraces motifs such as the trip into the other world (*Gilgamesh,* Dante, Milton), the dead speaking (François Villon), ghosts and vampirism (Bram Stoker), resurrection (the Bible), nirvana (Mircea Eliade), and the quest for immortality (Celtic legends of the Saint Grail). They all express human attitudes toward the mystery of death: fascination, fear, pity, sorrow, and denial. Concepts of death ranged from the means of access to another world or state (from substance to essence), to the irremediable end. For instance, in the symbolist theater (Maurice Maeterlinck), nothing happens but the tense waiting for the fatal force of death: The characters are paralyzed with fear and ramble in vague foreboding and mysterious impulsiveness.

The Death of the Self

The death of the self is not always feared but sometimes is desired. Indian literature portrays self-sacrifice as a conscious effort to transgress the human limitations in order to proceed to holiness or nirvana (*Upanishad*). Indeed, many social attitudes pertaining to suicide were influenced by the writings of the great thinkers and philosophers. Suicide was officially condemned by Cicero, Plato, and Aristotle, though in reality such self-destructive behavior was tolerated. Seneca's letters on death and suicide would remain for centuries a reference for the defenders of absolute liberty.

However, it is with the *Sturm und Drang* and the romantic dolorism movements that life began to imitate literature. Overwhelmed by an unsatisfying present, authors turned to the past, contemplating the graves and ruins; they were attracted by death as it delivered the spirit from the bodily prison, from an existence of suffering and a world of injustice. Thus, the cemetery became a favorite landscape. Disgusted with life, figures like young Werther in Germany (Johann Wolfgang Goethe) and René in France (René de Chateaubriand) became obsessed with the feeling of death, an obsession that was emblematic of the times and, concomitantly, held great influence upon the literature of the period.

In contrast, suicides such as that of Emma Bovary in Gustave Flaubert's naturalist novel, of Kiriloff in Fodor Mikahaïlovitch Dostoyevsky's realist novel, or of Jessie Cates in Marsha Norman's modern drama represent a different constitution. These suicides are sobering in presentation and professional literary critics of the time underlined their simplicity and veracity in opposition to the romantic suicide with its artificial hatred projected toward the world.

The Parnassians displayed an inner, grave, meditative attitude in their poetry, with a central place for the figure of death. Characterized by pessimism and Buddhist nihilism, the Parnassians considered pain inseparable from existence; aspiring to the nothingness of death seemed the only remedy. Charles Baudelaire excelled in depicting the history of a thrilling spiritual drama, a lifelong moral crisis that only found consolation in the temptation of a delivering death.

After World Wars I and II, suicide was increasingly apparent in both literature and reality. The absurdity of life depicted by existentialists has been interpreted as an attitude of avoidance, of dismissal in the face of the harshness of life. Some writers, however, such as Emil Cioran used expiatory literature as an alternative to the self-destruction impulse.

Eros and Thanatos

When analyzing literary depictions of death, scholars render special consideration to the theme of love, or the aspect of the oedipal complex. In *L'Amour et l'Occident,* Denis de Rougemont

developed the idea that since *Tristan and Isolde,* it has been impossible for writers to conceive of the theme of love without its concomitant relationship to death being considered. For instance, throughout the works of Marguerite Duras, there is a constant theme that partners *Eros* and *Thanatos;* the feminine character is only strengthened by the passion that violently pushes her lovers to suicide.

Historically, suicide has often been a form of blackmail as a strategy to regain love, for many thought that life without love is similar to death. The tragedies of the era depict the suicide of young people, victims of cunning schemes to disrupt their loving relationship. Again, in the sentimental and the romantic novel, death is the consequence of a broken heart as witnessed in *Clarissa* by Samuel Richardson, *Julie, or The New Heloise* by Jean-Jacques Rousseau, *The Young Werther's Sufferings* by Goethe, *Poor Lisa* by Nikolay Karamzin, and *Last Letters of Jacopo Ortis* by Ugo Foscolo.

Death as a Pretext for Writing

In general, grief and mourning are represented to assist in identifying fiction from history. However, this technique is not useful when applied to early literary works, because knowledge of those times is based solely on these same writings. Such tautology is not consistent with the emerging scientific ethos.

The Origins of Literature

The most ancient written literature are texts connected to the cult of dead (*The Book of the Dead, The Texts of the Sarcophagus, The Texts of the Pyramids,* Egypt, ca. 3300 B.C.E.). Based on popular verses, some incantation-like songs of sorrow evoke moments from the life of the departed while others try to prevent an enemy's spirit from returning to disturb the community (South America). The Sumero-Babylonian *Gilgamesh,* 28th century B.C.E., the earliest known literary work, contains the embryonic seed of mourning, death anxiety, and the quest for eternal life, or the secrets of the life beyond. A few centuries later, other writings were imbued with skepticism and profound pessimism in reaction to the official system of belief in life after death (*Conversation of a disappointed with his soul,* Egypt, 22nd century B.C.E.) or expressed the vanity of life (the Egyptian *Song of the Harpist,* the Hebraic *Ecclesiastes*). Indian and Greek funerals and religious hymns circulated in oral form until they were included in anthologies (*Rig Veda,* 1200–500 B.C.E.) or epics (*The Iliad,* 9th century B.C.E.). Thus, the motif of death such as mourning, bereavement and grief, life after death, and funerals are already present in literature. These themes developed throughout the centuries, in turn giving birth to other themes such as vampirism as a modern imagining of the life beyond.

Families Decline

Depictions of death have served well to explain the decline of the structure of the family. From the Indian epic (*Mahabharatta*) and Greek "theater of great passions" to German medieval literature (*Nibelungenlied*), Shakespearean tragedy (*Romeo and Juliet*) and French naturalist novels (*Thérèse Raquin* by Emile Zola), authors relied upon criminal impulses to cause the death of family members.

As a prototype of this genre, Eschol, Sophocles, and Euripides depicted intrafamily murders, with the underlying meanings ranging from the work of gods to human responsibility. In these works, the characters undergo the most violent, passionate, and tragic situations: A daughter is sent to death by her own father; a wife willingly sacrifices herself to save her husband; a mother kills the children of her son's murderer; a seduced and abandoned woman kisses her children good-bye before putting them to death; or a sister breaks the law in order to accomplish a funeral ritual.

With Shakespeare (*Hamlet, Macbeth, Othello*), the accent is placed at the level of the moral consciousness so that the murderer was no more than a victim. While French classicism, and later existentialism, also returned to the antique virtues of purity, the same mythic material of the past emerged with a sense of property and civil responsibility (Pierre Corneille, Jean Racine, Jean Anouilh, Jean-Paul Sartre).

Death Literature as an Entertaining Personality Cult

Personality cults developed and spread with the expansion of civilization during the Renaissance period, transforming the figurative representation of great persons as well as the manner in which

their lives were narrated. New literary forms and genres reconsidered the relationship between life and death. For these writers, literature was, and it remains, a way of being remembered (a postself) after death. Thus, the written text serves as a monument as well as a funeral tomb. Three centuries later, the French writer Alexandre Dumas commemorated his friend Nodier by writing a novel that, despite its expressed intent, turned out to be a pretext for Dumas to write his own eulogy.

Fascination of Death

Presenting the other as a viewpoint of the dead can help writers (or readers) assuage their fears and help master their fantasies about death. Through *belles lettres,* or savant discourse, literature examines the fascination of death through the representation of gladiators, martyrs, executions, or assisted suicides. However, recent literature takes a different track, no longer seeing this mysterious attraction as curiosity, but rather as thrill and charm. In the past century, as writers found that people had difficulty accepting tragic representations, death came to be portrayed as a humorous character (Terry Pratchett) or a cartoon illustration (Neil Gaiman).

Accordingly, in 1988, a group of multicultural collectors, in an attempt to lessen the dramatic representation of death in the Western world, gathered stories of celebration of the dead, including funerals and rituals, and especially plays, carnivals, and other happy festivals. The work was published in France; it led to the conclusion that the idea of death could be sublimed, transformed and transferred through sensations provided by language. Indeed, poetry and other forms of literature are ways of immortalizing the dead and death itself.

During this same period, Ruth Menahem argued that the need to write is inseparable from the wish to die. Language is a medium for impulsive representations to express oneself, so that the unconscious desire may accede to the conscious mind. Thus, the goal is to study the way in which fantasies of death are put into writing.

The Latter 20th Century: Critical Studies and Literary Depictions of Death

Literature reflects contemporary societies' understanding of death, whether the framework is religious, humanist, part of nature, or the disruption of life. Historically, the theme of death was within the purview of the metaphysicians and necromantics. During the latter portion of the 20th century, however, much interest was generated within a number of academic disciplines and practitioner-oriented professions, including history, psychology, anthropology, sociology, and medicine. It is within this context that literary critics provide increasing attention to literary depictions of death. Examples can be drawn for the work of Paul Barber who, in 1988, distinguished between the vampire of folklore and the vampire of fiction. He eventually investigated burial practices and finally considered death between folklore and reality. During the 1990s, Daniel E. Collins wrote of the treatment of death in Russian medieval literature. He identified six recurrent motifs in the description of the Muscovite monks' last hours (presentiment of death, last rites, transfer of power, convocation and admonition, obedience and the testament, parting forgiveness and blessings).

Collecting stories from the oral traditions around the world was also a major preoccupation of the 1990s, meaning to balance the silence that resulted from the institutionalization of the dying in modern societies. If some literary collectors put the accent on the festivities attached to the event of death, it is mainly to replace death among the living, as it was in ancient times.

Finally, the religious influence upon the literary works of the West was recognized by Allan T. Smith in 2006. Laurence Lerner focused on the Christian strategies of consolation with reference to child deaths depicted during the 19th century, while some feminist scholars gathered poems skillfully written by bereaved parents during the 17th and the 18th centuries.

Living a Legacy

The lives we lead are in themselves a legacy—mostly for good but sometimes not—although we may give little thought to what that legacy might contain. The immensely wealthy are able to leave a living legacy in the form of charitable foundations named after individuals or families who are thought to be inspirational, such as Ford, Fulbright, or Rockefeller. Such structured benevolence serves as a guiding light, be it through a devotion to art, education, medicine, or environmental protection.

A living legacy for most of us will be memories for family and friends and, for a few, an impression made on a larger stage. Some find it hard to contemplate their own demise but for those who can, thinking about the legacy they wish to leave enables them to generate a list of what they want to achieve and prioritize competing claims on their time and energy. Some goals are externally directed—for example, popular lists of 100 places to visit (or eat) before you die (a form of tourist and restaurant promotion)—in pursuit of new experiences. Others are more inclined toward a reflective lifestyle, mindfully appreciating and living the moment.

A positive awareness of the inevitability of death can intensify our appreciation of life. It encourages us to be more open with family members and to challenge the taboos that surround the subject, thus increasing the likelihood of achieving a "good" death, one without regrets. However, for many the reality is a sense of anxiety and denial about their own demise. Death anxiety stems from three possible sources: past-related regrets, future-related regrets, and the meaningfulness of death. Regrets are mostly caused by unfinished business usually concerning (a) relationships and reconciliation with loved ones, mostly apologies and forgiveness issues in intimate relationships, and not having the opportunity or ability to express love; (b) completion of key life tasks such as witnessing the marriages of children or attending the graduation ceremonies of grandchildren; (c) personal challenges or commitments like running a marathon, writing a book, making a dress, or helping to build a school for AIDS orphans; and (d) failing to fulfill personal promises to family and friends, for example, giving up smoking, repaying a debt, or writing a letter of introduction.

Creating a Shared Legacy

Although these issues affect all of us, they may be felt more intensely by those from collectivist cultures—for example, Chinese, Latino, and Jewish—where family relationships and individual identity are closely interwoven and where individual achievements are frequently perceived as family achievements. A satisfying and meaningful life with gratifying relationships, opportunity to finish unfinished business, and adequate closure leads to a peaceful departure from this world.

The ways that individuals share their lives and create legacies for others vary. Writing an autobiography is a popular form of sharing one's life. Family members may also produce their own written recollections of the departed, usually focusing on their strengths, talents, and virtues. Poems, artwork, portraits, and songs may also be used to promote the collective memory of individuals or communities. Those left behind often turn to religion and spiritual comfort in a search for the meaning of loss. In a survey of emotional responses to the September 11, 2001, terrorist attacks in the United States, 90% of respondents reported turning to religion as a direct consequence. It is the unexpected death that often causes the most distress, especially when it involves people who have much of their lives left to lead. But this can also create opportunities for a tangible and life-saving legacy—organ donation. In some ways this is the ultimate act of altruism, as many such donations are made to unrelated people. Not everyone is

comfortable with this kind of legacy but for those who are it creates the feeling that death was not entirely in vain and consoles the bereaved with the sense that their loved one still has a living presence on this earth.

Living legacies can be ambiguous or even negative. Service men and women who die in battle are heroes within their own countries because they gave everything for a righteous cause. The same people are war criminals to the invaded nation(s). Japanese soldiers who survived defeat were expected to kill themselves. It was the only honorable action left to them. Unsurprisingly they despised as cowards allied troops who allowed themselves to be captured. Many of those allied troops had been brought up to believe that suicide was a coward's escape. One faith's religious fanatics are another faith's holy martyrs who die with honor and fame in this life and gain Elysium in the next. In China suicide was traditionally the last resort of those desperate to make their voices heard. Government officials whose policy recommendations were rejected by the emperor would not infrequently kill themselves as a means to demonstrate their dedication to the well-being of the empire as well as the justness of their policies; a piece of advice is more important than one's own life. Following this example, suicide is still used by Chinese people to make their voice heard, to highlight unfair treatment or undeserved blame. In some eastern cultures, remarriage by widows was (and to some extend still is) unacceptable. In China, widows who died without remarrying were commemorated through a memorial plaque in the ancestor hall, a singular honor. In India the position was more extreme; widows were expected to burn alive on the funeral pyres of their husbands, a practice known as *suttee* and now illegal but still practiced in some rural areas of India. Such living legacies represent oppressive traditions for women and that rob them of choice and freedom.

Clinical Aspects of the Concept

The concept of living legacies has a clinical application in preparing people for the end of their life in a way that can be colorful and diverse. Discussion of one's life legacy can generate a sense of coherence, integrity, purpose, and meaning; enhance connectedness; affirm self; and address the aftermath of trauma. Individuals can be helped through a discussion that shares life wisdom, by visiting favorite places and retelling stories about the past that can be passed to the next generation.

Removing risk factors and strengthening protective factors by awakening the reasons for living has become a key focus in prevention intervention. People do not kill themselves when there are reasons to live. A life review can introduce the concept of living a life that is fulfilled, during which missions are accomplished and many fond memories are created.

Life review as an anticipatory mourning intervention is useful for tapping into a person's "unfinished business" and facilitating a "good" death. Life review can bring the best of the past into a functional relation with the present so as to strengthen positive support. When past good memories are reviewed, one can share lessons of living, inspire and encourage others, and affirm the values and meanings of relationships. Structured life reviews also are effective in helping depressed older adults in the reduction of depressive symptoms and enhancement of their satisfaction with life.

Constructive reappraisal of past events can lead to improvements in self-esteem, personal meaning, a sense of purpose, and a decline in hopelessness. Integrative expression of past events not only can enhance memory and cognitive functioning, it can also facilitate recall of past coping strategies and enhance coping by normalizing the distress and adversities in life.

Discussions about the legacies of our lives help us to deal with death, dying, loss, and bereavement as well as their impact on the ultimate reasons for living. Not only do they provide chances for us to process the meaning of death and integrate it into reality, they also help us to imbue our lives with appreciation and meaning. Without death, there is no life; without love, there is no grief. Grief over the loss and death of loved ones demonstrates the existence of intense love. Joan Berzoff has cited many examples of living a legacy in her book and articles. In particular she has focused on how bereavement experiences can be transformed into new meanings and sense of self for individuals. The tendency to medicalize or pathologize grief may not be in the best interest of bereaved persons' recovery and transformation through pain.

The Role of Cultural and Religious Beliefs and Practices

Benevolent practices based on patience, humility, wisdom, knowledge, courtesy, courage, love, justice, temperance, and transcendence are values in action. According to Buddhist teaching, values such as compassion, altruistic behavior, unselfish love, forgiveness, and loving kindness are keys to happiness. The bondage of hatred, anger, and jealousy, as well as thoughts of retaliation and revenge can become mental toxins that poison individuals' physical and mental well-being. Conversely, compassion is the best medicine for anger and rage through altruistic actions to eliminate the suffering of other people. By involvement in acts of compassion and loving kindness, individuals' hearts can be cleansed and their souls can be freed. That is why relationship reconciliation is a crucial pathway to dying in peace.

Highly respected religious and political leaders are shared role models in the provision of a living legacy. The father of independent India, Mohandas Gandhi, is dearly remembered by the world for his leadership of the nonviolent resistance movement against colonial rule and international domination. He used the hunger strike as a form of passive resistance, almost killing himself in the process. Such devotion to peaceful political action through self-sacrifice has given Gandhi a unique page in human history. Mother Teresa is still one of the most respected spiritual leaders. She promoted simplicity, love, and unconditional compassion, especially to the dying and those considered by others to be human rubbish on the streets of Calcutta. Successful business leaders such as Bill Gates and retired politicians such as former U.S. Vice President Al Gore have shifted the mission of their lives. Gates has refocused his energies on giving away the fortune he amassed, and Gore now devotes his public life to raising international consciousness about the imminent and long-term dangers of global warming. These are new missions and directions that these inspirational leaders now believe to be the most important parts of their lives and intend to devote their futures to achieving. They are certainly living legacies for the rest of the world. They encourage us to know what we want to achieve and contribute to humankind in a lifetime, albeit in more humble ways.

The human legacy could be one of gracious and full living, leaving a legacy of love for others. Reflection back on life with its attendant challenges and difficulties should bring satisfaction along with personal endurance and humility. Remembering how we overcame adversity should help us to recognize our strengths and persistence. More importantly, revisiting our past should enable us to identify priorities in life. The accumulation of much life wisdom that can be shared with the younger generations as a living legacy can enhance a sense of altruism, benevolence, and transcendence. Preparing for such a legacy can foster an appreciation of life, as well as courage to face adversities with perseverance.

Living Wills and Advance Directives

The medical profession in the United States has experienced a shift in ethics and values over the past 3 decades, from a position of paternalism to an emphasis on patient autonomy. As such, individuals are becoming increasingly involved in their medical care, especially with regard to decision making near the end of life. The desire to "control" the circumstances surrounding one's death has become the norm in the majority culture of the

United States, and several practices have evolved to help ensure that this is accomplished. Advance directives and advance care planning are two such concepts that are discussed in this entry.

Terminology

Near the end of life, patients and their families face a number of difficult decisions, such as whether to start or continue a given medical treatment. Advance directives are written documents that state an individual's wishes under specific conditions and in the event that he or she is no longer legally competent to make a decision. There are two general types of advance directives: durable power of attorney and living wills. A durable power of attorney (also known as a "health care proxy") designates an individual who will make decisions for the dying person when he or she is no longer competent to do so. A living will is a document that specifies in writing what kinds of treatment are and/or are not wanted by the individual under specific conditions.

In addition, there are two types of directives that are specific to certain treatment interventions: the do not resuscitate (DNR) order and the do not hospitalize (DNH) order. The DNR indicates that no resuscitation measures (typically cardiopulmonary resuscitation [CPR]) should be undertaken if the patient goes into cardiac or respiratory arrest. The DNH order states that the person or the responsible party (relative or legal guardian) does not want the person to be hospitalized. DNH orders are typically issued when an individual's pain management, comfort care, and current treatment needs can be met either at the person's home or in a nursing home. This does not mean that the patient can never be hospitalized, but simply that before the decision to hospitalize is made, a discussion needs to occur between the competent patient or patient's family/guardian (if the patient is incompetent) and the attending physician to determine if hospitalization is what is best for the patient.

History of Advance Directives

Although competent adults in the United States have long held the right to refuse life-sustaining medical treatment, individuals who were incompetent at the time a treatment decision was required, and their loved ones, had no option but to follow the decisions of the medical team. Marilyn Webb discussed several significant events that occurred between the late 1960s and the early 1990s and brought the concept of advanced directives to the attention of the public. This concept was introduced in 1967 when Luis Kutner, an attorney and member of the Euthanasia Society of America, proposed the first model of a living will. That same year, the Euthanasia Society began to distribute these model documents out to the public. In 1968 and again in 1973, Dr. Walter F. Sackett introduced a bill allowing patients to express their future desires regarding life-sustaining medical treatment to the Florida state legislature. However, the bill was defeated both times. In 1974, Barry Keene proposed a bill aimed at legalizing living wills called the Natural Death Act, but this too was defeated. It was not until the famous New Jersey Supreme Court ruling in the case of Karen Ann Quinlan in 1976 that proposals for advance directives were able to gain ground.

The events leading up to this case occurred in 1975, when the 21-year-old Quinlan went into a persistent vegetative state (PVS) after having accidentally ingested a potentially lethal combination of prescription medication and alcohol. At the time of her discovery, Karen had been unconscious and deprived of oxygen for at least 15 minutes, yet the medical staff used aggressive CPR in an attempt to revive her. All possible life-saving measures were taken to bring Karen out of the PVS, to no avail. After several months with no change, her medical doctors agreed that the chances were less than 1% that Karen would ever come out of the PVS. Her body had begun to shrivel and curl up into itself, and she would have frequent periods of involuntarily reflexes, such as grimacing, screaming, and crying. The doctors insisted Karen could not feel any pain, but it was very difficult for her family to watch her experience such suffering. After several months, Karen's family requested that her mechanical ventilator be removed so that she could die in peace. Karen's doctor initially agreed with Quinlan's family, but later recanted, stating it violated his moral values and contradicted established medical practice. This refusal began a long court battle for the Quinlan family who fought for the right to act as their daughter's legal guardian (because she was an adult at the time of her accident), and the right

to withdraw the life-sustaining treatment she was receiving. On March 31, 1976, 2 weeks shy of a year since Karen had gone into a PVS, the New Jersey Supreme Court ruled that Joe Quinlan, Karen's father, would be her legal guardian and would be entitled to make medical treatment decisions on her behalf.

According to Webb, 3 months after the Quinlan ruling, Barry Keene proposed his bill once again, which, this time, was successful. With the passing of the Natural Death Act, California became the first state to legalize one type of advance directive, the living will. By 1977, 42 states had made similar proposals, with seven of them passing. In 1983, California made yet another significant step forward and enacted the Durable Power of Attorney for Health Care law, becoming the first state to recognize this type of advance directive. Finally, by 1992, all 50 states had legalized some type of advance directive. Despite the legalization of living wills and durable power of attorney, incidence rates of completed advanced directives remain very low.

In 1983, another famous case brought public attention to how laws regarding an individual's right to die can vary by state. Nancy Cruzan was a 25-year-old woman who went into PVS after a serious car accident. She had been fed through a feeding tube inserted into her stomach for 4 years before her family asked the rehabilitation center to remove her feeding tube. When the center refused, fearing they would be committing murder, the Cruzans took their daughter's case to court. The Missouri courts, however, were initially reluctant to rule in favor of the Cruzans, stating that clear and convincing evidence of what Nancy would have wanted must be presented before a ruling could be made. Three years later, the U.S. Supreme Court heard the case and ruled that the guardians of incompetent patients could ask that treatment be withheld or withdrawn but that states could determine the level of evidence needed to allow such a decision to be acted upon. Eventually, the Cruzans were able to have Nancy's feeding tube removed after three of her friends testified that, prior to her accident, she had specifically told them that she never would have wanted to remain alive in a persistent vegetative state.

During the Cruzan case, Senator John Danforth proposed the Patient Self-Determination Act (PSDA). Implemented in 1991, the PSDA was seen at the time as a large step toward increasing the utilization of advanced directives. The PSDA requires hospitals, medical centers, and nursing homes that receive federal funds (primarily referring to Medicare and Medicaid) to inform all patients, upon admittance to the hospital, of their right to make their end-of-life wishes known in the form of an advanced directive. The goal of this act was to increase public awareness and completion of advance directives. Despite good intentions, the number of individuals completing advance directives has not increased significantly since the inception of the PSDA. Current estimates place the incidence rate of completed advance directives for the general U.S. population somewhere between 15% and 25%.

When Individuals Do Not Have Advance Directives

In general, there are three types of laws that may come into effect when individuals are not competent to make their own decisions: laws regarding (1) living wills, (2) durable power of attorney, or (3) family consent (a.k.a. surrogacy or succession laws). States may have any one or a combination of these three laws in place. Laws regarding living wills and durable power of attorney vary by state but typically set forth guidelines for which advance directives are recognized, when the advanced directive may be applied (e.g., only when the person has been diagnosed with a terminal illness), who is eligible to make decisions for the individual, and how the decision regarding care is made.

Surrogacy or succession laws typically come into play when no written instructions have been set forth by the patient. When this occurs, a family member hierarchy is employed to determine who is eligible to make the end-of-life decisions for the patient. Possible hierarchies differ by state, but one example for an older adult might be spouse, adult children, next closest adult relative, friend of family, and medical professional. Surrogacy or succession laws can be helpful not only when there are no written instructions, but also when more than one medical treatment may meet the criteria set by a patient's advanced directive and the medical doctor wants to know which alternative should be used. Surrogacy or succession laws are also used

when the patient's advanced directive is not entirely clear and needs to be clarified by someone who may know the patient's wishes.

Debate on the Utility of Advance Directives

As research on advance directives continues to accumulate, a number of questions have emerged in the literature, such as to what degree advance directives are utilized and followed, and whether they help to ease the burden experienced by family members. Some research has suggested that families of patients who have an advanced directive feel more involved in the decision-making process and more educated about what to expect near the end of their loved one's life. Studies have found that individuals who are more likely to have an advance directive tend to be older, white, more educated, less likely to have family who can make decisions for them, and more likely to be of higher socioeconomic status and at a higher level of cognitive functioning. Although not discussed in detail in this entry, as Jung Kwak and William Haley have noted, there are significant cultural differences in perceptions and use of advance directives.

Given this research, scholars and the public at large have continuously debated the utility of advance directives. Arguments for and against differ based on the advance directive in question, with some individuals being more in favor of one type over another. Proponents of living wills, for example, argue that this advanced directive offers the individual the most control over the circumstances surrounding his or her death and the most autonomy near the end of life. Opponents argue that it is impossible to predict every scenario that one may face and to provide treatment preferences for every possible end-of-life situation. Furthermore, they point out that individuals change their minds constantly throughout their lives as they gain more life experience. Thus, an individual's living will would have to be routinely updated at least every year to take these changes into consideration.

On the other hand, proponents of the durable power of attorney approach argue that unlike the living will, the designated decision maker can make a decision regarding the specific situation the patient is facing. Opponents, however, point out that the designated proxy may not follow the patient's wishes. For example, a daughter who holds her mother's durable power of attorney may be well aware that her mother never wanted to be put on a feeding tube, but may request that one be inserted because of her personal values or her difficulty accepting the terminality of her mother's condition. Another stated weakness of the durable power of attorney is that the designated proxy may be unaware of the patient's wishes in a given situation and thus may not be able to make an informed decision regarding medical treatment.

Some general problems with advance directives in addition to those already mentioned also exist. First, only a small percentage of the general population has an advance directive in place. Second, legal policies regarding advance directives vary by state. For example, in some states advanced directives apply only when an individual is terminally ill (typically defined as having less than 6 months to live) and do not cover situations where the patient is in a PVS and therefore can "live" in this condition for years. A third problem that expands on this is that many individuals do not fully understand the treatments they specify in their advanced directives. Research has consistently shown that many individuals do not understand how CPR works, what the survival rate of receiving CPR is, and the damage that can be caused to the body in the process. Studies have found that individuals often change their living wills after receiving this information. A final problem is that medical professionals are not routinely involved or consulted in the construction of advance directives. Research has shown that patients fill out advance directives primarily with their lawyer or family and rarely include their physician. This only adds to the problem of misinterpretation of what medical treatments entail and what purpose advance directives serve.

One possible solution to this debate has been the idea of "advance care planning." This approach emphasizes continued discussion between a patient and his or her health care provider that aims to clarify the patient's values and wishes regarding end-of-life care in general, as opposed to the patient stating what he or she would want done in every specific situation possible. This approach can also help incorporate individuals' shifting opinions as they age and transition through different life stages, as well as ensure that the physician is continuously involved in the planning process. Research has even suggested incorporating a

"values history" as part of the routine medical history that is taken in hospital settings, especially for elderly patients. A values history can assess personal values about quality of life, autonomy, family relations/burden, physical comfort and pain management, and treatment philosophy, to name a few. Understanding individuals' life values is important because such values are often associated with the likelihood of completing an advanced directive, as well as a patient's preferences for life-sustaining treatment such as CPR. For example, individuals who value quality of life over a desire to live as long as possible may be less likely to want extensive life-sustaining treatments near the end of life. This approach may even help the patient better understand his or her preferences regarding end-of-life care.

Conclusion

During the 20th century, several court cases and statutes have helped pave the way for incompetent individuals to exert some control over the circumstances surrounding their death. Yet, in spite of reforms that recognize the legal status of advance directives, debate surrounding the utility of these documents remains. At present, only a small proportion of the U.S. population has an advance directive in place, and states differ in their regulations regarding these documents. However, new approaches, such advance care planning, are evolving to address some of the limitations inherent in current advance directive practices. Although much research has been conducted on the utility of advance directives, the results are often mixed or incomplete. More research is needed to determine the approach to end-of-life care and decision making that will best address individuals' diverse preferences and needs near the end of life.

Loved One, The

The Loved One: An Anglo-American Tragedy (1948) is a satirical novel by the English novelist Evelyn Waugh (1903–1966) and is regarded by many critics as one of the best fictional works of the past century. The novel's unabashedly comic treatment of the subject of death and funeral customs was widely accepted by a postwar audience and paved the way for even more adventurous treatments of these themes in literature. *The Loved One* inspired critical examinations of the funeral industry and southern California's famous Forest Lawn Memorial Park in particular. The novel was also a progenitor of the "black humor" of the 1960s, evident in the 1965 film version of the novel.

Background and Summary

During a 1947 visit to California, Waugh made several visits to Glendale's Forest Lawn cemetery, which made an indelible impression. Once back in England, he immediately began work on a satirical novel based on American funeral customs. The novella's principal character is the young English poet Dennis Barlow, a typically bemused and passive Waugh anti-hero. Barlow is lodging in Los Angeles with the elderly expatriate screenwriter Sir Francis Hinsley. After being fired by the studio, Sir Francis commits suicide, leaving Dennis to deal with his remains. He visits the fabled Whispering Glades cemetery and meets the lovely cosmetician Aimée Thanatogenos (her first name comes from the evangelist Aimee Semple McPherson—a resident of Forest Lawn—and her surname means "born of death" in Greek), who introduces him to the various services that the mortuary can provide his "loved one."

Dennis becomes infatuated with Aimée, who seems more "decadent" and therefore more interesting than common American girls. Aimée and Dennis meet in a corner of Whispering Glades, where the girl tells him about how she became a cosmetician and about her love for transforming corpses. His rival is the expert embalmer Mr. Joyboy, known for his ability to put peaceful smiles on faces stiffened by rigor mortis. Dennis, meanwhile, toils away at the ovens of a pet cemetery, the Happier Hunting Ground, where he disposes of animal corpses while writing poetry. Joyboy offers Aimée a chance to become the first female embalmer at the cemetery and takes her home to meet his mother.

Aimée is torn between her admiration for Joyboy's professional skills and her love for Dennis's poetic nature and writes to a newspaper "advice-to-the-lovelorn" columnist, who is in reality the cigar-chewing Mr. Slump. Barlow pitches woo, but the romance comes to a sudden end when Aimée accompanies Mr. Joyboy to his mother's parrot's funeral and finds Dennis at the pet cemetery. She immediately decides to become engaged to the embalmer, and she and Dennis have a final meeting in which he expresses his cynicism about the funeral trade. Mr. Joyboy, on the other hand, proves to be more attached to his mother and her bird than his fiancée, leaving her in a state of agitation. After the advice columnist advises her to take a leap, she decides instead to return to Whispering Glades and commit suicide by taking cyanide and injecting herself with the embalming needle. Worried by the possible damage to his reputation arising from her death, Joyboy agrees to turn Aimée's corpse over for disposal in the animal crematorium, while Dennis cynically accepts hush money from both Joyboy and the expatriates, who pay him to take the next plane back to England.

Analysis and Significance

The Loved One was published in book form first in the United States and later in Britain; despite Waugh's wariness about its reception, both critics and the general public in both countries accepted the more gruesome aspects of the book. Perhaps the horrors of the war had prepared them for such subjects. While so-called dark humor involving the pointless or absurd deaths of characters is characteristic of many British novels of the interwar period (including Waugh's) and has been described as a coping mechanism for dealing with modern life, there are few precedents—Robert Louis Stevenson's *The Wrong Box* is one—for Waugh's relentless use of corpses, embalming, cremation, suicide, and other "black" subjects for comic effect.

Waugh's satire focuses on several targets, including the excesses of postwar American culture, the narcissism of the English expatriates in California, and the phoniness of Hollywood. These all derive from the author's evident disgust with American culture. But the prime object of his satire is the funeral industry, the modern metropolises of death, and their attempts to deny death and the dissolution of the body. For a full understanding of the novel, it is necessary to understand that Waugh had converted to Catholicism in 1928 and that his spiritual outlook informs all of his subsequent fiction. Beginning with *Vile Bodies* (1930), Waugh's novels tend to contrast the materialism of modern life with a worldview founded on the Catholic faith, tradition, and political conservatism. The very notion of "vile bodies," with its biblical allusion to the inevitable corruption of the flesh, suggests the religious underpinnings of Waugh's social satire.

Waugh's most pointed satirical thrusts are reserved for the meretricious physical environment of Whispering Glades. Waugh's own library, now

at the University of Texas at Austin, contains a view book with fulsome descriptions of Forest Lawn's glades, lakes, and parks such as "Slumberland" and "Dawn of Tomorrow." He hardly needed to embellish these at all to achieve a comic effect, and indeed his fictional memorial park is nearly a carbon copy of the real thing. Significantly, Whispering Glades is nestled next to Hollywood, the capital of illusion and artifice. Most of the statues in the park are replicas of well-known classical sculpture and historical figures, yet they exploit the past for commercial gain rather than pay homage to it. History and popular culture absurdly rub shoulders. Throughout the park, superficiality and artifice are the order of the day, reflecting the nightmarish vision of Dr. Wilbur Kenworthy, the "Dreamer," who is based very closely on the real founder of Forest Lawn, Dr. Hubert Eaton, known as the "Builder." Like Eaton, Kenworthy (who does not actually appear in the book) has sanitized death by placing his cemetery in the midst of a pleasant park-like atmosphere, with fountains, tall trees, and statuary. Moreover, Kenworthy, like Eaton, was an innovator in locating his funeral home in the cemetery itself and employing a host of marketing schemes to persuade vulnerable relatives that their "loved ones" required more expensive caskets and arrangements. Waugh also satirizes Eaton's euphemistically named "pre-need planning," an innovation designed to sell overpriced funeral packages to the living.

The novel continually moves back and forth between the sordid realities of death—for example, Sir Francis's hanged body with its lolling black tongue—and the hygienic embalming room and antiseptic viewing rooms of Whispering Glades. Aimee's cosmetology and Mr. Joyboy's efforts to resculpt the gruesome expressions on dead faces are attempts to cover over the horror of death and result in an "obscene travesty." Callous and venal though he is, Mr. Schultz, the cynical owner of the Happier Hunting Ground pet cemetery, at least acknowledges the actuality of death and is not interested in covering over the stench of death with the cloying aroma of disinfectant.

Influence

A decade and a half after its publication, Waugh's novel had a major influence on Jessica Mitford's celebrated investigative book *The American Way of Death* (1963), later revised as *The American Way of Death Revisited* (1989). Mitford was a member of the well-known English clan closely associated with Waugh (her sister Nancy was one of his most faithful correspondents and the dedicatee of *The Loved One*). It was Waugh who surely inspired Mitford's coolly ironic descriptions of Forest Lawn, its phony classical statuary, its canned music, sanitized parlors, and the contrasts between the venality of its "funeral directors" (i.e., morticians) and their smarmy empathy for the bereaved. One of the principal themes shared by both books is the use of euphemistic language to cover up the unpleasant realities of death and loss. Nancy Mitford (1996, p. 458) wrote to Waugh that Jessica's book was in effect "a factual *Loved One*." The exposé was widely reviewed, became a best seller, and made the author an instant celebrity. Waugh himself gave *The American Way of Death* a generally favorable notice, praising its humor, but referred to the lack of "a plainly stated attitude to death."

In 1965, *The Loved One* became a feature film directed by Tony Richardson and starring Robert Morse as Dennis Barlow and Anjanette Comer as Aimée. The screenplay by Terry Southern (with contributions by Christopher Isherwood) pushed the envelope of what was acceptable in a Hollywood film and was advertised as "the motion picture with something to offend everyone," although it now seems rather tame. Eschewing Waugh's dry, spare wit, Southern's adaptation put more emphasis on sexual innuendo, the macabre, and the dark side of the funeral industry. He added several elements not in the original novel, including a grotesque eating scene at Mrs. Joyboy's house and an unctuous casket salesman played by Liberace. A new plot line, involving Dr. Kenworthy's brother and corpses being rocketed into outer space, reflects the intersection of death and the space age. Richardson's direction stressed broad physical comedy and encouraged overplaying (not that Jonathan Winters, with a memorable role as Dr. Kenworthy, the sinister "Dreamer" behind Whispering Glades, needed any encouragement). The result was a movie that was unsatisfactory to most devotees of the book, although it achieved minor cult status and has been re-released on DVD. It also inspired an episode of the BBC (British Broadcasting Corporation) series *Dr. Who*.

In regard to its black humor and treatment of death, the film should be paired with Southern's nearly contemporaneous *Dr. Strangelove* (1964). Both movies attempted to shock moviegoers—*The Loved One*, with its violation of various taboos concerning death and funeral customs, and *Dr. Strangelove,* with its attack on the folly of "mutually assured destruction." The latter features an apocalyptic ending with an accidental nuclear holocaust set ironically against the World War II tune "We'll Meet Again." Both films reflect an increasing acceptance of what would be known as "black humor" or "black comedy," which features ostensibly serious subjects not formerly associated with humor, such as cremation or mass nuclear annihilation. Significantly, Bruce J. Friedman's seminal anthology *Black Humor* appeared in 1965, the same year as the filmed version of *The Loved One*. Both films and black humor in general are recognizable as responses to traumatic events of the early 1960s, including the Cuban Missile Crisis and the Kennedy assassination, which made the unthinkable suddenly thinkable. Black humor can also be regarded as a pushing from a Freudian perspective. Black humor provides a way for the subconscious to deal with the prospect of its own annihilation, which became a very real prospect in this era.

Waugh's small satiric masterpiece remains remarkably fresh and relevant today, a useful antidote for the persistent mortician-speak of "preneed planning" and "loved ones" that may still be found in advertising for funeral homes and cemeteries, including Forest Lawn's web pages. The novel retains its ability to startle and usefully reminds one that death *can* be a laughing matter.

Lynching and Vigilante Justice

Lynching, also referred to as lynch law and Lynch's law, is the illegal execution by a mob of a person suspected of a crime or some other prohibited behavior. Lynching is today a felony in the United States. A separate felony category is second degree lynching (an attempted execution by a mob where the victim survives). The method of execution most frequently associated with lynching is hanging, but that has not always been the case. The law now includes any mob action that could result in death.

Origins of the Concepts

The concept of lynching appears to have started as a reference to executions ordered by Charles Lynch in 1780. Lynch was a militia officer in America's War of Independence and a justice of the peace. He joined with other officers to try men suspected of disloyalty to the new American nation in an unofficial court of their own creation. Executions were ordered and carried out, along with whipping, seizure of property, forced loyalty oaths, and service in the military for those who were not executed. The victims of these summary executions were Tories who maintained loyalty to England. The actions of Lynch and his companions were legitimized when the Virginia General Assembly later approved their actions in 1782. It was these executions that forever linked the name Lynch and the term *lynching* to the concept of vigilante justice.

The term *lynching* originated in the eastern part of the United States. The term *vigilante* originated in the U.S. Southwest. The word *vigilante* comes

from the Latin *vigilans,* meaning "to watch." In Spanish and Portuguese the term *vigilante* means a "watchman." Unlike someone who commits a lynching, a vigilante is not necessarily a criminal. Vigilante conduct is officially disapproved because of its potential to yield to criminal behavior by the vigilante. Neither "lynch justice" nor "vigilante justice" is held by any recognized authority to be either legal or just.

Political Reaction to the Term *Lynching*

Although it originally had no racial component, the term *lynching* has come to describe crimes against African Americans. The special connection between lynching and race began in reference to the murders of both blacks and of abolitionists in the 1830s. In St. Louis in 1836, Elijah Lovejoy published an account of the lynching of an African American man. He also reported on the trial and acquittal of the killers. His report so angered opponents to abolition that his press was destroyed by a white mob. When Lovejoy secured a new press, it was also destroyed and Lovejoy was shot and killed. The motivating factor in both deaths was opposition to freedom for blacks.

After the Civil War, the Ku Klux Klan began widespread use of lynching and the threat of lynching to try to maintain white supremacy in the post–Civil War South. According to statistics from the Tuskegee Institute, 1886 was the first year in which the number of African Americans lynched exceeded that of whites (although blacks comprised a far smaller percentage of the overall population).

One of the first investigations into lynching was carried out by the editor of a Memphis newspaper, Ida Wells. In 1884 she discovered that during one period 728 black men and women had been lynched by white mobs. Of these deaths, two thirds were for small offenses such as public drunkenness or shoplifting. Lynch law was changing, now being applied based on the race of the alleged offender. When, in March 1892, three African American businessmen were lynched in Memphis, Wells published a condemnation of the murderers and referred to them as lynchers. In response to her article, a white mob destroyed her printing press. At that time the leaders of the mob stated they intended that Wells would share the earlier fate of Elijah Lovejoy, but she was away from Memphis on a trip when the attack occurred.

Continued threats on her life made it necessary for her to relocate and she took a position with the newspaper, *New York Age*. There she continued her campaign against lynching and its legal counterpart, Jim Crow laws (legislation passed to prevent blacks from exercising their rights, especially the right to vote).

One of the earliest black politicians to speak out against lynching was George Henry White, the last former slave to serve in Congress and, at that time, the only African American in the House of Representatives. In January 1901, Congressman White proposed the first bill to make lynching a federal crime. He argued that any person participating in, or acting as an accessory to, a lynching should be convicted of treason. White pointed out that lynching was being used by white mobs in the South to subjugate African Americans. He showed that 87 of the people lynched in 1899 were African Americans (80% of all lynchings). In spite of White's efforts and evidence, the bill was defeated.

Extent of the Crime

The exact number of lynching victims may never be known. There is disagreement among sources. However, the most commonly cited figures of numbers of people killed by lynching come from the Archives of Tuskegee Institute. The institute was founded in 1881 with Booker T. Washington as its first teacher. From its founding, the institute, now part of Tuskegee University in Tuskegee, Alabama, compiled data on lynchings based on newspaper accounts and letters from across the United States. The figures from the Tuskegee Institute shown in the tables are telling; of the 4,743 lynching deaths unofficially recorded for the period 1886 through 1964 and shown in the Tuskegee Institute archives, 73% victims were black.

The NAACP Fight Against Lynching

Almost 2 decades after Congressman White's bill was defeated, the fight for antilynching legislation was picked up by the National Association for the Advancement of Colored People (NAACP). The NAACP fought a long campaign against lynching

and tried to educate Americans and others about the nature of this practice. In 1919, the NAACP published *Thirty Years of Lynching in the United States: 1889–1918*, and it placed paid advertisements in newspapers across the United States to present facts about lynching.

A decline in lynching occurred during World War I, but in the year after the war ended, more than 70 blacks were lynched. Ten black soldiers, several still in their army uniforms, were among those murdered. Some had served in the most highly decorated unit in the American Expeditionary Force in World War I. In the postwar years of 1919 to 1922, 239 blacks were lynched by white mobs. More were killed by individual acts of violence and in lynchings that were never recorded. Not one white person was punished for these hundreds of crimes.

Some whites were also lynched during these years, for example, the leaders of trade unions, including Frank Little and Wesley Everest, two members of the Industrial Workers of the World. These killings might be seen as examples of vigilante justice, since they were used by those who were watching out for dangers to the United States at home and abroad. However, they can be seen as lynching because they mirrored in many ways the executions ordered by Charles Lynch to punish "enemies" of his country.

"Strange Fruit"

The jazz song "Strange Fruit" has come to be considered an anthem of the antilynching movement. In 1937, a New York schoolteacher saw a photograph of the lynching of Thomas Shipp and Abram

Smith. The teacher, Abel Meeropol, later said that the photograph haunted him and that it inspired him to write the poem "Strange Fruit." Meeropol, using a pen name, Lewis Allan, published the poem in the *New York Teacher.*

After seeing Billie Holiday perform in New York, Meeropol showed her his poem. Holiday liked it and turned it into the song "Strange Fruit." The record was popular in 1939, but the song was denounced by *Time* magazine as "a prime piece of musical propaganda" for the NAACP. But the original photograph of the lynching of Shipp and Smith, along with the poem and song that the picture inspired, played a role in creating greater opposition to lynching in the United States.

The Michael Donald Case: NAACP Versus the Klan

In 1981 Josephus Andersonan, an African American, was brought to trial in Mobile, Alabama, charged with the murder of a white policeman. The jury could not agree on a verdict. Some members of the Ku Klux Klan believed that this was because some members of the jury were African Americans. At a meeting held after the trial, Bennie Hays, an official of the Klan in Alabama, is said to have declared that if a black man can get away with killing a white man, a white man ought to be able to get away with killing a black man.

On March 21, Henry Hays, son of the Klan official, and James Knowles decided they would exact justice themselves for the failure of the courts to convict the murderer of a policeman. The pair drove around Mobile and saw a young black man, Michael Donald, walking home. They forced 19-year-old Donald into their car, drove him to the next county, and lynched him. After a brief investigation, the local police announced that Donald had been murdered as a result of a disagreement over drugs. Donald's mother, Beulah Mae Donald, knew her son had never been involved with illegal drugs and decided to fight for justice. She contacted Jesse Jackson, who came to Mobile and led a march to protest the police investigation, which appeared either haphazard or, at worst, part of a conspiracy.

Agent James Bodman of the Federal Bureau of Investigation was able to persuade James Knowles to confess to the killing of Michael Donald. In June 1983, Knowles was found guilty of violating Donald's civil rights and was sentenced to life imprisonment. Six months later, when Henry Hays was tried for murder, Knowles appeared as the chief prosecution witness. Hays was found guilty and sentenced to death.

The Southern Poverty Law Center convinced Beulah Mae Donald that her case could destroy the Ku Klux Klan in Alabama. Her civil suit against the United Klans of America reached the court in February 1987. The all-white jury found the Klan responsible for the lynching of Michael Donald and ordered it to pay $7 million. This caused the Klan to surrender its national headquarters in Tuscaloosa County, Alabama. When Henry Hays was executed in June 1997, it was the first time a white man had been executed for a crime against an African American since 1913.

Reinterpretation of Lynching

The term *lynching* had taken on a new meaning, almost exclusively racial, by the beginning of the 21st century. It was seen by some as any unjust accusation or attack against an African American. In October 1991, at his confirmation hearings, Supreme Court nominee Clarence Thomas was questioned about his alleged sexual harassment of a staff member of his office. It appeared that he might not secure Senate confirmation of his appointment to the Supreme Court. In a passionate statement, Thomas referred to the attacks on his character by the predominantly white Senate committee as an example of a "high tech lynching." The passion aroused by that statement helped to hasten his confirmation.

In January 2008, for using the term *lynching*, sports reporter Kelly Tilghman was suspended from her position for 2 weeks. In speaking about the dominance of a minority golfer, she said that young players wanted to "lynch him in a back alley." At the time, in calling for her to be censured, one civil rights activist said that the term *lynch* was offensive to all blacks. His comments, limiting the term to blacks, demonstrate that the meaning and application of a word can change over time, for social or political reasons.

Vigilante Justice

Vigilante justice in the southwestern United States was most often applied by a posse who pursued

suspected wrongdoers and, after catching them, handed out their own justice. The scene has become part of American culture through novels, films, and television. The men who formed the posse were often sworn in, with authority much like that claimed by Charles Lynch. They watched for threats to citizens, their property, and the law. However, when they abandoned their charge to bring the accused lawbreakers back for trial and carried out their own sentence and executed prisoners, they crossed a line by breaking the law themselves.

Vigilantes, unlike the mobs who lynched those said to have violated some rule of behavior, at least appeared to have the trappings of a court. There was often some form of hearing where the accused offered a defense. During the California Gold Rush of 1849, an increase in crime and violence in San Francisco led to the creation of a vigilance committee. The committee consisted of 600 local volunteers, chiefly prominent citizens. In 1851, the committee hanged 4 men, had 1 whipped, and deported 20 others. However, they also found over 40 not guilty and released them after their "trial." This committee was disbanded after a year because there had been a major decline in violence and crime. The remoteness of mining camps put their residents outside of any official legal authority. To try to prevent chaos, communities often established a vigilance committee and gave this group the combined roles of jury, judge, and executioner. When law enforcement officers arrived, vigilance committees were typically abandoned.

An example of modern vigilantes who offer security and keep watch for lawbreakers can be seen in the "Guardian Angels." This organization was founded in New York City by Curtis Sliwa in 1979. The Guardian Angels now have chapters in cities throughout the United States and abroad. However, in spite of the positive record of the Guardian Angels, there remains in vigilantism the potential to cross the line and to become judges and executioners.

There are those today who defend vigilantes and their role. Indeed, some analysts argue there may be a role again for community vigilantes. Such a case may have been the death in 1980 of a town bully who was shot to death as he sat in his truck in Skidmore, Missouri. The victim seemed to be the modern embodiment of the desperados that vigilance committees were intended to apprehend in the Old West. He had been accused of molesting young girls, rustling livestock, stealing grain, and burglarizing farmhouses. These alleged crimes took place in four states, but the accused escaped conviction by intimidating witnesses and even law enforcement officers.

The entire town of Skidmore lived in fear. Whoever crossed the town bully risked receiving intimidating phone calls, night visits, even death threats. The people believed that the bully might well be above the law. The murder was never solved and may have been a case of the town carrying out modern vigilante justice.

The Minuteman Project

A more recent vigilante group is the Minuteman Project. The Minuteman Project was started April 2005 by private citizens to "watch" the U.S.–Mexico border. Their intent was to report on and to lessen the flow of illegal immigrants into the United States. The founder of the group named it for the Massachusetts militiamen who fought in the American Revolution. The members describe themselves as "a citizens' Neighborhood Watch on our border." They have attracted attention to the issue of illegal immigration. The Minutemen also have aroused strong emotions among opponents and supporters.

Opponents have said the Minutemen associate with neo-Nazis and skinheads, but no actual link has been proven. The Mexican and U.S. presidents have expressed their distrust for vigilante group actions on the U.S.–Mexico border. But the worst problem known to have been caused by Minutemen was the accidental tripping of sensors along the American side of the U.S.–Mexico border.

Supporters have praised the work of the Minutemen. The governor of California, Arnold Schwarzenegger, said he welcomed minuteman patrols on the California–Mexico border. Supporters applaud their efforts to help the border patrol and feel their protests are merely legitimate expression protected by their right to freedom of expression. Opponents protest the actions and protests staged by the Minutemen. These mixed reactions illustrate the mixed feelings found among Americans who believe that official channels may

not be effective in keeping watch over U.S. borders in these difficult times.

Make-A-Wish Foundation

The Make-A-Wish Foundation is one of several foundations that grants wishes to children with life-threatening conditions. It is a nonprofit organization that brightens the lives of gravely ill children by fulfilling their wishes to go, be, meet, or have whatever they have wished for. The largest wish-granting organization in the world, the foundation has helped over 148,000 children by funding vacations, career explorations, celebrity interactions, and gifts, among other wishes. Founded in 1980, it operates 69 chapters in the United States and its territories and runs a global affiliate called Make-A-Wish International.

The foundation is an outgrowth of the Chris Greicius Make-A-Wish Memorial, the fund established in memory of a terminally ill boy who received his wish to become a police officer after being named an honorary member of the Arizona Department of Public Safety. Greicius's mother, Linda Bergendahl-Pauling, and two police officers who were active in this initial wish granting effort, Frank Shankwitz and Scott Stahl, along with Kathy McMorris and Allan Schmidt, cofounded the Memorial and spearheaded its transformation into the foundation.

When granting wishes, the foundation uses a four-step process. First, the candidate is referred by a medical professional, parent, or legal guardian, or is self-nominated. Candidates must be between the ages of 2 and a half and 18 years old in order to be eligible for a wish. Second, the severity of the child's condition is assessed to determine if it is sufficiently life threatening. Potential wish children must have a degenerative, progressive, or malignant medical condition but it need not be terminal. Third, one of the foundation's 25,000 volunteers is deployed to assist the child in developing a wish. These volunteers help wish children search their imaginations for something that will bring them happiness. Finally, the child's wish is implemented. Though many wish children are "terminal" or "dying," the foundation does not use these words in its interactions and actively de-emphasizes the mention of illness and clinical treatments.

The philosophy of the foundation is to better the human experience by bringing strength, hope, and joy to wish children, their families, and their supporters. It enacts this philosophy by providing wish children and their families with a temporary retreat from the harsh realities of serious illness and by involving donors, communities, volunteers, and sponsors in these life-changing efforts.

Funding, Supporters, and Operations

Make-A-Wish covers all expenses associated with the granting of a wish, including those tied to family member participation. With more than 78% of every donated dollar devoted to wish granting, the majority of the foundation's incoming funds are directly applied to these altruistic expenditures. This proportion of charitable pass-through is above the threshold set by the Council of Better Business Bureaus' Wise Giving Alliance, indicating

that the foundation exceeds this watchdog organization's program service standards. On average, a wish costs $6,450 and is granted without regard to socioeconomic status, race, or gender. These funds are often devoted to one of the following wishes: visiting a Disney theme park (41.5%), traveling (19.3%), going on a shopping spree (10.9%), receiving a new computer/electronics (8.7%), and interacting with a celebrity (6.1%). Make-A-Wish estimates that it grants a wish every 41 minutes.

The foundation's first wish child was Frank Salazar, a 7-year-old with dreams of becoming a firefighter. Prior to his death, the foundation arranged for Salazar to become an honorary member of Phoenix Arizona's Fire Department and organized his visit to its firehouse. Media attention surrounding this wish prompted community and corporate involvement in the foundation's efforts. As a result, Salazar gained a hot air balloon ride and a trip to the Disneyland theme park; the foundation won public recognition and the advocacy of the Walt Disney Company.

Disney has remained one of the foundation's primary supporters and it is currently among the organization's largest financial donors. The foundation enjoys similar levels of monetary support from Macy's and also earns sizable annual contributions from American Airlines, Delta Airlines, U.S. Airways, General Motors, Avis Rent A Car, UnitedHealth Group, and Things Remembered. Corporate donations are named by four categories of annual giving: Mission Champions are at $5 million and over, Wish Champions are at $1.5 million and over, Cause Champions are at $500,000 and over, and Fund Raising Advocates are at $250,000 and over. The foundation also has Promotional Supporters, entities that provide $500,000 or more in advertising and awareness contributions, and Corporate Donors, firms that give products or services to Make-A-Wish.

In addition to corporate support, the foundation relies on individual contributors to achieve its mission. Such individuals often assist by making financial contributions through monthly giving, estate planning, and honor, memorial, or general donations. Individual donors are similarly invited to give in-kind items, frequent flier miles, and hotel reward points or shop at the foundation's online auctions, the Make-A-Wish Store, or one of the organization's partner retailers. The foundation also welcomes the human resources of those willing to lend their time and talents to its wish granting mission. These volunteer efforts may involve being one of the foundation's staff volunteers or helping organize a local event that raises funds and awareness for Make-A-Wish. Awareness is also cultivated by individuals who purchase a Wish Star, a magnetic symbol of support for the foundation's goals.

The monies received from corporate and individual donations represent the largest source of the foundation's annual revenues of approximately $180 million. These funds are put to use by a management team based at the Make-A-Wish headquarters in Phoenix, Arizona. This team is accountable to the foundation's National Board of Directors. The management team also receives guidance from Make-A-Wish's National Advisory Council, a coalition of influential individuals and celebrities that stimulate awareness and support for the foundation.

Malthusian Theory of Population Growth

The Malthusian theory of population growth addresses the ability of the human species to

increase in population size and to eventually reproduce itself beyond its own ability to grow enough food to sustain this ever-expanding population size within the limits of a defined habitat. Population growth is exponential, while the ability of Homo sapiens to grow food is arithmetic. The consequences of this imbalance in population growth and available food supply would, according to Malthus, either be corrected through human intervention resulting in maintaining an appropriate balance between population size and available food equilibrium or the population would be reduced in size through consequences that include disease, epidemics, famine, and war. In the following text, the authors address the utility of the Malthusian theory by applying its basic tenets to population issues.

Malthus's Principle of Population

Thomas Robert Malthus was born in England in 1766. He was educated at Jesus College in Cambridge. At the age of 22, he became a curate near his family home in Surrey and later in Lincolnshire. In 1805, he was appointed a professor of history and political economy at East India College, Hailerbury, a position he occupied until his death in 1834.

It was during his early years as a rural clergyman when, at age 32, he published anonymously the first edition of his famous work, *An Essay on the Principle of Population as It Affects the Future Improvement of Society, with Remarks on the Speculations of Mr. Goodwin, Mr. Condorcet, and Other Writers* (1798). This was mainly a deductive book of around 55,000 words, whereas the second edition expanded his theory and provided a great deal of illustrative data, resulting in around 200,000 words. Subsequent editions, ending in the seventh edition published posthumously in 1872, included relatively minor changes.

Malthus's main argument was that the growth of a population results from the natural urge to reproduce. But material resources, such as food and shelter, cannot keep pace with this growth in human population because these material resources increase at an arithmetic rate (1–2–3–4–5–6–7), while population growth occurs at a geometric rate (1–2–4–8–16–32–64–128). If unchecked, population levels would double in size about every 25 years. Because productive capacity can never maintain this rate for long, the growth in population must be continually checked. Malthus based this estimate on observations of actual population growth in the New World, where resources were once abundant for the relatively small population size. Assuming an initial quantity of 1 unit, in 225 years, the population would be at 512 billion—billions more than at time 1. Yet in that same time period, the means of subsistence would only have increased by 10. In 2,000 years, the difference between population and production would almost be incalculable.

Malthus argued that population growth was held in check in two ways, by preventive checks and by positive checks. The major preventive check was moral restraint, such as the postponement of marriage and abstinence from sexual activity. The positive checks included wars, famine, pestilence, and other forms of misery. If the population was left unchecked, it would grow much faster than material resources and lead to human misery, ultimately resulting in poverty. The checks were divided into two subgroups including misery and vice. Misery included things such as hunger, poverty, and disease, and vice included prostitution, venereal disease, homosexuality, and abortion.

Later Editions of the Principle of Population

In 1803, Malthus published the second edition of his essay, this time under his name, with a different subtitle, namely, *or a View of Its Past and Present Effects on Human Happiness; With an Inquiry Into our Prospects Respecting the Future Removal or Mitigation of the Evils Which It Occasions*. Malthus's second edition of the essay was written as a result of his travels in search of ethnographic and statistical evidence to support his principle of population. In this essay, he focused more on moral restraint as a means to limit the number of births. In addition to the theory of progress, his second essay was also concerned with questions of practice. Under the assumption that the principle of population was thought to be a natural law, Malthus wanted to see if human action could remove or limit its evil effects. Focus was also introduced here on moral restraint; that is, the postponement of marriage until an individual had

prospects for supporting a family. Malthus believed that the only way to avoid the brutal forces of misery and vice was through moral restraint. Although little changed in Malthus's later writings and revisions of the *Principle of Population,* he did note that humans have the ability to control their actions more than population growth is a natural power.

The Theory of Population in Modern Day

Malthus's essay brought into controversy the idea of human perfectibility, which was a prominent ideology in the wake of the French Revolution. Malthus sought to espouse notions of human perfectibility because his beliefs were that scarcity would occur because of overpopulation. His theory opposed two influential schools of thought, mercantilism and utopianism. Malthus's theory was based on two assumptions. He believed that food was necessary for the existence of man and that the passion that exists between the sexes is necessary and will remain at its current state. His theory addresses the consequences on the human population when food and other forms of sustenance are inadequate to sustain a population within its habitat.

The problem is that if human population growth goes unchecked, it will grow faster than the earth can produce subsistence for. Malthus believed that the two powers, subsistence and the growth of the human population, must be kept in balance. In order to keep this balance, misery occurs due to the power of the population to overwhelm resources. Malthus further explained that misery does not fall evenly on all sections of a population, but mostly on the poor.

Several important historical and contemporary examples would appear to support, at least in part, Malthus's claim. Such examples are the Irish potato blight of the 1845 to 1847, the famines of Africa, overpopulation in China, India's lack of an adequate and safe water supply, the U.S. corn epidemic of 1970, and the unprecedented population growth in developing countries.

The main form of sustenance for the population of Ireland in the early 1800s was the potato. In the years 1845 and 1846, the potato crops failed resulting in a great famine. More than 1 million people died and, over the course of the next 5 years, more than 2 million people emigrated. Within a decade, the population of Ireland declined from more than 8 million people to less than 6 million. The crops were also affected in the United States, Canada, and around Europe in those years, but these countries were not as affected. Because Ireland was overpopulated and the farmers were forced to export other crops, such as corn, wheat, barley, and oats, potatoes were the only remaining subsistence for the majority of the Irish people. Although other countries were able to turn to other sources for food, the Irish did not have enough nutritious food to support their population, which resulted in death and emigration.

In sub-Saharan Africa, evidence of positive checks on the population includes drought, poverty, and a shortage of land, which limits food production. AIDS is also reducing life expectancy in many African countries. These factors, as well as the great famines occurring in the 20th century, have reduced the total population. Famines have occurred in Nigeria in 1968 to 1969; West African Sahel in 1969 to 1974; Ethiopia in 1972 to 1974, 1983 to 1984, and 1989 to 1990; Angolia in 1974 to 1976 and 1993 to 1994; Mozambique in 1985 to 1986; Sudan in 1984, 1988, 1993, and 1998; and Somalia in 1984, 1988, and 1992. Many of these famines occurred because of poor rainfall and crop failure, like in the West African Sahel and Ethiopia. For other countries, food supplies were barely adequate but became scarce when wars caused more disruption.

China is a good example of expediential growth that leads to overpopulation of a human habitat. China is the most populous nation in the world, reporting a population in 2008 of over 1.3 billion. China represents more than one-fifth of the human race. In 1959 and 1960, China experienced an estimated 30 million deaths due to starvation and disease, or positive checks that resulted from an economic calamity caused by economic policy and natural disasters. Although China did experience positive checks during this time, preventive checks may be more apparent recently. Malthus argued that preventive checks were the most influential in the Western world and positive checks in the rest of the world, especially in China.

Other evidence of Malthus's argument includes the increasing population of the developing world.

Two-thirds of the world population lives in developing countries. By the end of the 21st century, three-fourths of the population are projected to be living in developing countries. However, there is doubt that food production will be able to keep up with this population growth. The scarcity of fresh water to sustain a growing population could also be a positive check. India, for example, is drawing underground water at twice the rate of recharge. More than half of India's food comes from irrigated land, and many of its children are undernourished.

The Malthusian Legacy

Malthus's essays have sparked much debate. Today, scholars are still debating Malthus's ideas. Many nonbelievers note that Malthus's arithmetic analysis is faulty. However, Malthus always held that population growth was greater than subsistence.

Despite such debate, Malthus did influence many scholars, including Charles Darwin, Herbert Spencer, David Ricardo, and John Maynard Keynes, among many other analysts of the day. One illustration of this influence is a statement attributed to Charles Darwin in his *Autobiography:*

> Fifteen months after I had begun my systematic enquiry, I happened to read for amusement Malthus on population, and being well prepared to appreciate the struggle for existence which everywhere goes on from long-continued observation of the habits of animals and plants, it at once struck me that under these circumstances favorable variations would tend to be preserved and unfavorable ones be destroyed. The result of this would be a new species. Here, then, I had at last got a theory by which to work.

MANSLAUGHTER

The crime of manslaughter has evolved over the centuries from a mitigation of murder to crimes committed under levels of criminal culpability. The offense of manslaughter in some states can be defined as the reckless or criminal negligent killing of a human being. Recklessness involves the conscious disregard of gross risks of harm that law abiding or reasonable people will attempt to avoid. Criminal negligence involves the unconscious creation of a risk of harm that is a gross deviation from the conduct of a reasonable person. It is sometimes difficult to determine if a person committed a reckless or a negligent killing.

Brief Historical Background

The criminal law is intended to protect the public good and to deter crime by imposing punishment for wrongdoing. During the Middle Ages, English customs and mores that were based upon Judeo-Christian teachings made it wrong to kill another person. These killings could be avenged by the victim's family, and blood feuds ensued when families disputed the culpability owed to one family by another. From the year 1066, when William I became the first King of England and for several centuries thereafter, the English crown formalized the law by making individual wrongs a crime against the crown. Thus, it came to be the aggrieved party and punishments were to be meted out in the name of the king. Most offenses, including homicide, were deemed felony offenses that were punishable by death. Because someone was killed, however, did not mean in a technical sense

that a crime was committed. Two categories of killing were distinguishable up through the 16th century, criminal homicide (or murder) and justified homicide. Murder was defined as the unlawful taking of another person's life without justification. But one would not be punished by law if the killing occurred in self-defense.

By the 17th century, the criminal law was sufficiently developed that criminal homicides were distinguished into the categories of murder and manslaughter. During this time period, use of the death penalty began to be placed under intense scrutiny. In response, common laws were created to distinguish felonies by taking into consideration the mental state (mens rea) of the accused. Murder, denoted as the killing of a human being with malice, was mitigated to a charge of manslaughter if the act could be demonstrated to have occurred without malice. Rather, the loss of life occurred because the accused acted from the heat of passion or provocation by the victim. This distinction between murder and manslaughter is basic to the present day.

Common Law and Heat of Passion Killings

Unlawful killings at common law were categorized as murder unless the defendant could show that the offense was committed under the heat of passion and was provoked by the victim. But provocation, it was held, had to be so intense that the offender could not control his or her behavior and acted in response to such provocation. In addition, the killing had to occur while the offender's passions were aroused. If a reasonable amount of time were to transpire to allow the perpetrator to become calm, the offense would not be mitigated and the offender would be tried in criminal court for murder and, if found guilty, sentenced to death. If tried and convicted of manslaughter, the sentence was for one year of imprisonment and with the thumb of the perpetrator branded as a signal to the public that punishment had been meted out. In the latter instance, provocation had to be proven and be directly tied to the event at the time the killing took place.

The common law recognized four types of adequate provocation. First, the crime of murder could be mitigated to a manslaughter charge if a man killed his wife while found in the act of adultery. Initially, the mitigation rules applied only to the killing of a wife, but common law cases extended the principle to the killing of a wife's paramour by the enraged husband. The law did not initially recognize such mitigation if a wife found her husband in a similar adulterous act. This killing was categorized as murder. Second, use of force in self-defense (imperfect self-defense) could be claimed as adequate provocation. Although the offender was not justified to using more force than necessary to repel an attack, the offender's passion in defense of self was deemed less blameworthy to warrant a charge of manslaughter. Third, feudal England social norms allowed men to defend their honor. However, mutual combat initiated by both parties in the name of preserving names and reputation did not completely justify the killing of one of the king's people. Fourth, the common law allowed a person to struggle to prevent unlawful arrest. If the struggle resulted in the death of the person effectuating the arrest, then the offense was mitigated to manslaughter.

Modern Refinements in Manslaughter Principles Law

By the mid-20th century, most states had codified the common law opting to establish criminal law statutes that are consistent with the needs of the modern era. Many states use the American Law Institute's Model Penal Code for guidance. Under the code, the law no longer allows mitigation of murder to manslaughter if the offender was engaged in mutual combat or resisted arrest. Early in the 19th century, the social conduct moral rules that previously tolerated dueling to preserve one's honor were abandoned. In the 20th century, the law pertaining to the use of force by social enforcement agents recognized the danger associated with arresting arrest. To protect both law enforcement agents and the public from the risk associated with force, the common law principle that allowed one to resist unlawful arrests was rescinded. Instead, such claims of unlawful arrest are expected to be made a court of law.

Only two reasons remain in support of the charge of manslaughter provocation rule, namely, adultery and imperfect self-defense. During the mid-20th century, heat of passion mitigation was extended to wives; nonmarried significant partners

are still not covered. The purpose of the law continues to support the principle that only married people who discover their partner committing adultery will naturally become passionately aroused. Imperfect self-defense rules allow for mitigation because, but for the conduct of the victim, the fight would not have occurred. Thus, it is recognized within the context of contemporary criminal law that the offender's anger was prompted by the victim's provocation.

Inadequate provocation exists in those situations when a reasonable person would not become inflamed. Under the common law, inadequate provocation exists when the victim engages in verbal confrontation. If a fight is provoked through of physical force, the offender can be expected use reasonable force in the attempt to repel the attacker. However, deadly force is never justified to repel verbal provocations alone. In states that follow the Model Penal Code's formulation of voluntary manslaughter, the heat of passion rule was broadened to include killings committed under extreme emotional distress. It is up to juries to determine the nature and quality of the extreme distress that would constitute a mitigated factor in a homicide.

Other Modern Manslaughter Crimes

In addition to manslaughter based on the heat of passion, newer manslaughter offenses are currently acknowledged. These offenses punish people who kill another because of their inability to differentiae between right and wrong (the mens rea concept), which is considered less blameworthy than malice. Although some states maintain the common law mental element of malice and malice aforethought, most states opt to use modern mens rea terminology as legal elements of a crime. Modern mens rea is interpreted to include the state of intent or purpose, knowledge, recklessness, and criminal negligence. Although thought by some analysts to be less ambiguous than the common law term malice, the lack of communication between mental health professionals and officers of the court continue to be in conflict.

Manslaughter offenses can also be used to punish people who kill another in unique social conditions. Under the federal law, judges sentencing offenders convicted of manslaughter can consider factors associated with domestic violence, long-term abuse of the offender by the victim, the type of weapon used and how the offender came into its possession, the length of time between the provocation and the homicide, and whether the offender suffers from a mental condition that affects his or her perception. Thus, federal sentencing guidelines differentiate manslaughter sentences based upon the degree of provocation (low, medium, or high) and if mitigating and aggravating factors exist. Offenses where the offender killed a victim who exhibited a low degree of provocation have a sentencing range of 10 years to life. Offenses with a substantial degree of provocation result in a sentence range of four to nine years.

Finally, in some states, the court is attempting to address whether manslaughter has been committed if during the course of employment a death occurs. Some state prosecutors are taking to trial companies and their corporate officers when an industrial accident claims the life of an employee and the accident is found to be the result of reckless disregard of safety standards proposed for the industry. Recent laws that enhance punishments for people distributing drugs that enhance another person's death can affect the practice of medicine for terminal patients. Health care practitioners also worry that they may be held criminally liable for the death of a terminally patient who commits suicide or for prescribing medications that are used to induce death. As recently as 2006, one state, Colorado, responded by modifying a pertinent statute to avoid punishing medical worker caregivers who prescribe high doses of pain relief for terminal patients.

Voluntary manslaughter law continues to evolve. Manslaughter remains a lesser offense than murder; but some common law principles are being modified as the focus moves from the offender's perspective to that of the victim. The law continues to mitigate murder when reasonable people respond to the stresses of life and the aggressions of another by use of force. But determining whether manslaughter should continue to be mitigated by adultery is currently being challenged in state courts. Ultimately, what is reasonable is a matter for a jury to decide. But as our sociocultural norms change, change in the parameters of the law referring to manslaughter will undoubtedly also continue to evolve.

Martyrs and Martyrdom

The word martyr comes from the Greek noun *martus* meaning "witness." But the term martyr in general speech is used elastically. Often little distinction is made between someone who puts up with difficult circumstances and is therefore considered a bit of a martyr, someone of political significance who is assassinated and subsequently proclaimed a martyr, someone caught in the cross fire of a political or religious confrontation or conflict and dies a martyr, or someone who believes so strongly in something that they are willing to die a heroic, often violent death as a result of remaining steadfast in their convictions and so die rather than relinquish or concede their faith or ideals. Thus, the way martyrs and martyrdom is interpreted is fundamentally interdependent with the sociocultural, religious, and political context in which it occurs; one person's martyr is another person's traitor, suicide, or victim. The features of a successful martyr will subsequently be identified, and the nature and function of a range of martyrologies from early Jewish, Christian, and Islamic tradition will be outlined.

Through martyrdom, the martyr creates a boundary between his or her own belief system and the belief system of the oppressing and ultimately murderous other. The boundary is literalized through the action of martyrdom in a way that provides evidence of independent identity and gives increased value to the beliefs of those who support the martyr—their cause is something worth dying for. Those who may have lacked direction and focus may gain cohesion through the martyr's action. However, dying a martyr may not have an easily quantifiable or immediate effect; Christianity, for example, had to wait another 300 years after the death of Christ and the writings of Matthew, Luke, Mark, John, and Peter before the faith was truly recognized.

How to Become an Effective Martyr

For a martyr's death to achieve the maximum effect, a number of processes are necessary: the martyr must have suffered, the oppressor must be perceived as evil and unjust by the audience of the martyr's narrative, the martyr must have acted in defiance of the oppressor, and finally, the martyr must die. Preferably, spectators to the martyrdom are complicit or acquiesce in the face of the challenge posed; they might have taken action to support the oppressed but did not. These people, ideally, should feel guilty for their lack of resolve when faced with "evil." It is this guilt that can be utilized to rally people together to "right" the "wrong" experienced by the martyr and to join together against the "evil" or ruling/oppressive forces. A collective desire to expiate the failure to intervene is the reason behind a number of commemorative rituals practiced by certain faith communities: Lent for Christians or the Ashura commemoration for Shiite Muslims are examples. In addition, the event must gain publicity through an audience. This audience may not be physically present during the martyrdom, but it is essential that the event is communicated through some agent so that the important performance and narrative of death is passed on and made a part of historical memory.

This communication is just as important, or perhaps even more so, than the death itself, for

without this narrative, the impact of the martyrdom can have little or no efficacy. With a powerful and evocative narrative of events, however, the act of martyrdom can be used as a persuasive tool for consolidating belief and gaining converts. However, not every martyr's story is equally successful in inspiring conversion or in reinforcing the core aims and beliefs of a group of people. The best martyrologies have a global impact and can communicate across cultures.

Key Features of a Martyrology

To be effective, a martyrology should tell a story that the audience is able to easily identify with. It must be told at a time when there is not so much bloody sacrifice occurring that people are immune to the effect of a death. In effect, a religious or political movement will pick and choose from the range of martyrologies available in order to promote those narratives that most effectively convey their system of beliefs and that have a resonance that is likely to be a source of inspiration both at the time of the martyrdom and in the future. Furthermore, in order for death as a martyr to perpetuate the martyr's memory and cause, careful attention must be paid to the performance of the martyr's death. The martyr must die well. A "good" death is one that demonstrates exceptional self-control; in the face of the agonies to be endured, the martyr remains steadfast. When an opportunity to rescind or escape is offered, the martyr refuses. Hagiographic accounts of the process of martyrdom often linger on the gruesome details of torture and dismemberment. The martyrs in these descriptions remain unperturbed, lucid, loyal, and unmovable in their conviction. Indeed, the excruciating encounters typified in the records of their dying are often recounted as transformational experiences, the unbearable agony exceeding all boundaries of sensation and becoming a kind of impassioned, divine ecstasy.

Early Martyrs and Their Martyrologies

While Socrates is often represented as the first martyr in Hellenic tradition, having stubbornly stuck to his beliefs in spite of pressure from the state, he is also an exception to a number of the conditions previously outlined; he did not die for the sake of a cause that would outlive him, nor did his death by hemlock produce a suffering body. Instead, it is from Jewish tradition that the earliest accounts (Maccabees Books 2 and 4) of the use of martyrdom for eschatological purposes are found. These books tell the story of how certain determined individuals contributed to the liberation of the Jewish people from the tyranny of the Selucid King Antiochus IV Epiphanes (175–164 B.C.E.). One narrative that appears in Maccabees 2 and 4 tells of the martyr Eleazer, a 90-year-old man professed to be a sage, who was persecuted for upholding the sacred laws of Judaism and refusing to eat pork. This happened at a time of widespread Jewish persecution (ca. 305–70 B.C.E.). Eleazer not only died for his beliefs but also so that his steadfastness would be seen as a role model for others who might be persuaded to acquiesce in the face of torture or enticements to rescind their faith and its practices. While the process of his death is hideous (he is whipped to death), the nobility of his choice bestows dignity on his death. The other extraordinary martyrdoms recorded in Maccabees concern a mother (in the Talmud she is named Miriam bat Tanhum) and her seven sons, who were all brought before Antiochus IV for refusing to consume pork. All gladly gave their lives so that the Jewish people could be cleansed of their shortcomings. The deaths were interpreted as a means of seeking reconciliation with an enraged God who was punishing His chosen people for straying from the path He had set for them; through the suffering of this woman and her children, the Jewish people might be expiated of their sins, Israel might be protected, and faith perpetuated. Ultimately, the Selucid Empire fell some 50 years later as a result of Jewish and other anti-Hellenic resistance.

The most famous Jewish martyr, however, remains Jesus Christ. His story of sacrifice and suffering is a foundational one for the Christian faith. Since this death, Christianity has accrued a rich history of martyrs that continues to the present. Arguably the most representative of these early accounts are the martyrdom of Stephen and of Polycarp. Stephen's narrative is recounted in Acts 6:8–15 and 7:1–60 of the Bible. Stephen was a bold and determined preacher who, following Christ's death, was responsible for claiming Christ was the Messiah. He had a vision of heaven before his death by stoning at the hands of the Sanhedrin,

who was enraged by Stephen's claims. His martyrdom is significant because his firsthand experience of Christ gives his story authenticity and legitimacy. The martyrdom of Polycarp provides a historically and ideologically important narrative for different reasons.

The account of Polycarp's martyrdom forms part of early Christian writings believed to be recorded by the Apostolic Fathers—in other words, the writings of people who are thought to have had firsthand contact with Christ's apostles. The story tells of the persecution of Christians in Smyrna, with particular emphasis on the death of the Bishop Polycarp at the age of 86. It is written as a letter from the church of the Smyrnaeans to the church of Philomelium. While it praises the actions of Polycarp, it warns against the seeking out of martyrdom. The contrasting stories of Quintus and Polycarp are juxtaposed to illustrate this point.

The martyrdom of Polycarp is used as an example of the difference between an attempt at self-aggrandizement represented in the person of Quintus and that of self-effacement—represented by the figure of Polycarp. At the core of the account are the differing decisions of each man. Quintus, actively seeking martyrdom, turns himself over to the authorities and in doing so exercises his own will and judgment. By contrast, Polycarp waits patiently; always ready to sacrifice himself but never putting himself forward as a candidate for martyrdom. In other words, Polycarp exercises complete submission, whereas Quintus chooses to take matters into his own hands. It is this choice that is the key. Polycarp understands that it is only a judgment for God to make when and if he is arrested and later martyred. Whereas Quintus, seeking martyrdom and all that it entails in terms of salvation and immortality, decides to act for himself. Quintus fails as a result of his choice because without God working with and within him he is not able to withstand the torture and suffering that is his lot. Polycarp, having waited for God to act, enjoys God's grace in the face of his martyrdom and by this means is able to endure all that he is required to suffer. The narrative is there to demonstrate that God is the power at work, not individual will, and that without the power of God an individual could not possibly accept and endure the agonies allotted them in martyrdom. God's power is made manifest, not the power of the individual chosen for martyrdom. This distinction is the hallmark of Christian martyrdom and contrasts with the definitions proposed by other faith communities. For instance, after the seventh century Islamic conquest of Palestine, the Arabs translated the Greek term for witness into Arabic: *shahid*. The concept of martyrs and this word is likely to have come into use during the time of early Islam, when there were still Christian churches in Palestine and Greek was still used. The word shahid refers to men who die at the hands of non-Muslims, and more broadly to those who sacrifice their life as a result of being a witness to their faith. With this definition of a martyr, it is perfectly acceptable to seek out death in the interests of one's faith. In addition, no distinction need be made between those who die for their faith and those who die for reasons of faith and kill others in the process. In contrast to concepts linked to early Christian and Jewish martyrdom, Islamic tradition has always had fighting martyrs who engage in holy struggle or jihad.

The Prophet Muhammad took part in numerous battles and while he himself didn't seek to be a martyr, he is recorded at the Battle of Badr as encouraging warriors to do so. Indeed, Umayr b. al-Humam, a member of the Banu Salima clan, in response to the prophet's words, stated that there was nothing to stop him gaining entry to paradise except the deaths of some infidels, at which point he threw aside the dates he was eating, grabbed his sword, and headed off into battle where he died. To die "in battle" gains the deceased immediate entry into paradise. Life is not then the limit of existence, because martyrdom offers the possibility of immortality and endless pleasure, as well as a sort of revenge and triumph over enemies who are thwarted through the act of martyrdom. This understanding of martyrdom allows any fighting action carried out in the name of faith that results in death to become a story of martyrdom.

Massacres

The word *massacre* is host to a number of different meanings but most commonly refers to individual events of deliberate and direct mass killings. The term especially takes into account noncombatant civilians or other innocents who have no reasonable means of defense. In this sense, the term massacre does not typically apply to combatants, although the deliberate killing of prisoners of war would most often qualify for this distinction.

At the same time, the term massacre is used more widely to refer to individual, civil, or military killings on a smaller scale, but having a distinct political significance of shaping subsequent events. Individual or small group murders may also be described as massacres, as would be the case in school and post office shootings. At the same time, the term massacre is often used for political or propaganda purposes, and the choice to label an event as a massacre or not may become quite sensitive.

The sheer number and volume of incidents labeled massacres makes coherent exposition somewhat daunting. To provide coherence and structure to the issue, massacres will be divided into four categories: war and terror, sociopolitical events, ethnic conflict, and anomic/criminal behavior. Understandably, any given event will often fall into more than one category, but sufficient homogeneity should exist within each category to make this approach worthwhile.

War and Terror

The early part of the 21st century has been witness to the widespread use of the concept of terror to explain repeated incidents of multiple deaths, although the concept has been around for some time and is considered by many to be a form of warfare. The incident known as 9/11, in which thousands of Americans were massacred by militant terrorists, has come to symbolize modern terrorism. Indeed, modern terrorists have come to view their activity as warfare. Throughout history, war and terror have been inextricably linked.

During the early years of American history there were numerous incidents of massacre involving the Indian population. On December 29, 1890, several hundred Sioux were camped on the banks of Wounded Knee Creek. They were intercepted by the U.S. Army and a shootout ensued. As a result, some 300 Indians and 25 soldiers were dead.

The American Civil War was also witness to numerous massacres. Probably one of the best known was the Lawrence massacre in 1863. The Lawrence massacre was the result of Quantrill's Raiders' attack on Lawrence, Kansas, which was a pro-Union town and had long supported abolition. Prior to this incident, many raiders from Lawrence had attacked and burned proslavery farms in Missouri. Quantrill's raid was in retaliation. The raid left about 200 adult and young males dead; women were spared. Many of the raiders were caught by angry mobs and lynched on the spot.

World War II was especially productive of massacres related to war. During the Japanese occupation of Nanking (1937) over 300,000 unarmed and defenseless civilians were massacred by Japanese troops. The massacre was so large that it lasted for over six weeks. In 1945, during the battle for the Philippines, retreating Japanese forces massacred over 100,000 unarmed civilians, which included many children. European history also contained massacres. In 1945, during the Battle of the Bulge, advancing German soldiers took many American prisoners. In a field near the Belgian town of Malmedy, German forces massacred almost 100 American soldiers.

Even the Olympic Games have not been spared the scourge of massacre. In 1972, at Munich, Germany, terrorists broke into the housing areas

and killed two Israeli athletes and took nine hostages. In a subsequent shootout with German security forces, all hostages and terrorists were killed. Nor have schools been spared. In early September 2004, in the Russian town of Beslan, terrorists took over 1,100 people hostage, including 777 children. Subsequent assault by Russian security forces left 334 hostages, including 186 children and the terrorists, dead.

Sociopolitical Events

The variety and magnitude of social and political conditions that can lead to massacres is virtually without limit. Such conditions can exist in the most advanced countries as well as the least developed.

Agitation for political rights has proven a fruitful spawning ground for massacres. In 1770, prior to the American Revolution, British troops were sent to Boston to maintain order. In response to torment from protestors, British troops fired into the crowd and killed five people.

On August 16, 1819, at St. Peter's Field in Manchester, England, a peaceful crowd gathered to petition Parliament to repeal the Corn Laws. Cavalry troops charged into the crowd and killed 11 people.

Massacres motivated by political conditions are found everywhere. In May 1980, in Seoul, South Korea, students were protesting a military coup. The military responded with force and over 200 people were killed. In December 2005, 14 civilians were killed by troops in Nepal as they protested government policies and had called a general strike. On August 13, 1985, government forces in Peru gunned down 69 civilians near the village of Accomarca.

In June 1989, the Chinese government used deadly force against protesting students who were unarmed. The students were protesting for more democracy in that country. At least 700 were massacred, although some estimates go much higher.

Economic conditions also are conducive to massacres. In 1897, near Hazelton, Pennsylvania, 400 mine strikers were fired at by the local sheriff and his deputies. Nineteen strikers were killed. For the first time in American history, the National Guard was called to restore order. In June 1922, near Herrin, Illinois, a mine strike led to the hiring of scabs. Over 50 scabs were killed by striking miners.

Ethnic Conflict

Ethnicity is defined as a shared cultural heritage. Ethnicity provides a fertile ground for massacres. Both large and small, massacres occur on an all-too-regular basis, and the underlying reason often appears to be ethnic differences. In the Darfur region of the Sudan, for example, there have been ongoing massacres since at least 1998 in which thousands have been killed. Arab ethnics have been migrating from the north and conducting massacres against the indigenous populations, which are mostly ethnic Masalits.

Ethnically related massacres have also taken place in Rwanda and Cambodia. In Rwanda there had been a long-term conflict between ethnic Hutus and Tutsis, but in the mid-1990s this conflict erupted into some large massacres. In 1993, about 300,000 Hutus were killed by Tutsis. The following year, Hutus killed over 500,000 Tutsis in retaliation.

After the United States withdrew from Vietnam in 1975, Pol Pot and the Khmer Rouge came to power in Cambodia. Pol Pot set about killing Cambodians who opposed his rigid policies, but eventually he turned on the minority groups as well. Ethnic Vietnamese, Chinese, and Cham Muslims were massacred. Over 50% of the Chinese ethnic group was killed. In 1979, in response, Vietnam attacked Cambodia and drove Pol Pot from power.

Early American history is replete with massacres rooted in ethnic differences, especially between whites and Indians. As early as November 1729, at Fort Rosalie in Mississippi (city of Natchez today), scores of whites were massacred by Natchez Indians. Reports at the time noted that even unborn babies were cut from the womb of pregnant women.

In Pennsylvania during July 1778, several hundred whites were massacred by Indians at the instigation of the British troops leading to the American Revolution. It was common for the British and the French to use Indians as allies against their enemies because they would completely annihilate the enemy.

During the American Civil War, hundreds of whites were massacred in the Dakota Territories by Indians in what came to be known as the Great Sioux Uprising of 1862. Over 300 Indians were tried and sentenced to death for the atrocity, but President Lincoln reduced the number executed to 38 Indians. Two chiefs who had led the uprising were kidnapped from Canada and subsequently executed.

In 1853, a federal survey team of 10 people headed by Captain Gunnison was attacked and massacred by Indians at the behest and with the support of Mormons. Gunnison had written a book critical of the Mormons to which they took exception. Subsequent trial of eight Indians for the massacre only produced light sentences (3 years each for manslaughter) much to the chagrin of the federal government, but much to the delight of the Mormon juries.

In Sri Lanka during October 1987, Indian ethnics from the Indian Army massacred almost the entire medical staff and most of the patients in a hospital. The final death toll was 68 ethnic Tamils, including 3 physicians.

During the ethnic conflict in Bosnia following the breakup of Yugoslavia, a whole series of massacres took place on both sides of the conflict. One of the worst was at Sebrenicia during 1995, in which thousands of Bosnian Muslims were killed by Serb ethnics. This event was the worst case of ethnic violence in Europe since the end of World War II.

Anomic/Criminal Behavior

Of the various types of massacres, probably the most difficult to understand are those that appear to emanate from forces beyond anyone's control, either as a consequence of crime itself, or as a result of anomie. Emile Durkheim defined as anomie the condition in which society had come to provide little or no moral guidance to individuals. Many massacres, especially in schools, seem to provide the message that moral guidance has gone awry with terrible consequences.

On April 16, 2007, a troubled student at Virginia Tech University, over a period of 2 hours, killed 32 students and faculty, wounded many others, and eventually committed suicide. That the student's problems were known to the university and police before the incident made the matter even worse and called into question the entire issue of gun control.

The Virginia Tech University incident was actually the most recent in an ever-growing list of school massacres in the United States, and copied in other countries around the world. The worst school massacre in terms of number killed was the Bath School in the state of Michigan. On May 18, 1927, three bombings at the Bath School killed 45 and injured 58. A school board member, who was angry about an increase in taxes, killed his wife and burned down his farm early that morning, then went to the school and detonated several bombs. The last bomb was a car bomb that exploded and killed him while firefighters were attempting to put out the fires that were started by previous bombings. Over a quarter ton of explosives that had not detonated were later found inside the school.

On August 1, 1966, a student at the University of Texas climbed to the top of the Administrative building with many weapons and ammunition. He subsequently killed 14 and wounded another 31 before being killed by the police. On April 20, 1999, at Columbine School near Denver, 2 students went on a rampage with guns and killed 12 students and teachers and then committed suicide.

The condition is not confined to the United States. On December 6, 1989, at the Ecole Polytechnique in Montreal, Quebec, Marc Lepine killed 14 women and wounded 10 men and 4 women. Written notes left behind (he committed suicide at the scene) claimed that he was "fighting feminism." On August 16, 1991, Wade Frankum entered the Strathfield Mall with a semiautomatic rifle and killed 6 people and then hacked a 15-year-old girl to death with a knife. He committed suicide at the scene. In February 4, 2007, two immigrants entered a Chinese restaurant in Stade, Germany, and gunned down 7 people. Some of the victims had been tortured before being killed. On September 24, 2008, Matti Saari entered a vocational school where he was a student in town of Kauhajoki, Finland, and killed 9 students. He committed suicide at the scene. The shooter had previously posted a video, but according to the police they were powerless to stop the shooter.

Finally, there are simple, criminal massacres, of which the most famous in the United States is known as the St. Valentine's Day Massacre. On

February 14, 1929, seven men were massacred in a garage in Chicago, Illinois. The murders were the result of gang warfare over turf.

A summary of these examples may not be plausible at this time. Given the variety of examples as shown in this entry, studies that strive to identify possible causes for why massacres occur are unable to provide a conclusive explanation.

Mass Suicide

Mass suicide is defined as the death of a large group of people who wanted to die, sought to die together at a predetermined or approximate time, and acted in a voluntary and intentional manner to produce this outcome. These key features distinguish the mass suicide from other types of suicidal behaviors, such as unrelated anomic suicides during times of profound social change, or cluster suicides, caused by the Werther effect, where the lyrics of a song or a piece of literature depicting suicide allegedly promotes copycat behaviors among people who encountered the art work. The mass suicide occupies a prominent place in studies on destructive communal behavior, and is a universal, albeit rare, cultural phenomenon. Some important historical and contemporary examples of mass suicide, the causes of this group behavior, various typologies of mass suicides, and the roles of religion and charismatic leadership in specific cases are discussed.

Historical Examples

Many of the historic examples of mass suicides have one thing in common: They were often a form of political protest by a group of people singled out on the basis of race, religion, ethnicity, or some other collective identity. These groups, the members of which viewed themselves as victims of state repression or an unfair social system, employed the mass suicide as a means of escaping tyranny or to avoid capture and death at the hands of an enemy perceived as cruel or unjust. Mass suicides were a potent remonstration and Pyrrhic victory for the deceased, who were often assured of receiving a sense of symbolic immortality in the memories of future generations who would tell of their heroic, fearless, and audacious termination at their own hands.

Jauhar

In medieval India, the practice of mass self-immolation, called *Jauhar,* was a type of suicide behavior largely associated with women and children, and meant to ensure an honorable death in the face of defeat by an invading army. In Jauhar, women would build a large funeral pyre and collectively hurl themselves—and their children—into the flames. Jauhar signaled that there was no other honorable alternative for the women survivors because their fathers, husbands, and sons had been defeated in war, and that seizure by the invading army would probably mean mass humiliation as subjected prisoners, or worse, sexual debasement. Mass suicide by self-immolation was a last act of collective resistance and the only available mechanism of ensuring the honor of the group. The most frequently cited historic example of Jauhar, in the literature on mass suicide in India, is the women of the Fort of Chittor, who committed mass self-immolation after defeat by an invading army. Led by Queen Padmini, the women of Chittor decided on self-immolation after the failed, yet valiant, effort of their kinsmen to defend their sovereignty against the invading military of the Sultan of Delhi, Allah-ud-din Khilji.

Russian Old Believers

Another historic case of the mass suicide as a politically driven action was the Russian Old Believers in the late 17th and 18th centuries. The schism that led to acts of mass suicide by the Russian Old Believers began with reforms that were implemented by Nikon, the Patriarch of the

Russian Orthodox Church under the auspices of Tsar Alexis. These religious reforms were intended to realign the liturgics of Russian Orthodoxy with Greek Orthodox practices. Nikon believed that the Russian Orthodox Church had severely strayed from the strict liturgical customs preserved by their Greek counterparts, and he wanted the Russian Believers to come back to a more traditional ritual. Many Russian Believers felt that Nikon did not have authority to impose this new system of reforms, especially because the Tsar was supporting his actions, and a split ensued between those who supported the change and those who were faithful the "old" Russian liturgy, under the leadership of Archpriest Avvakum. The Russian Old Believers saw the reforms as a signal that the eschatological apocalypse was near. Mass suicide, by collective self-immolation, was the chosen instrument by which many Old Believers sought to protest against the increasingly life-threatening persecution they encountered from the State and from the now-reformed Russian Orthodox church. In fact, thousands of Believers participated in a succession of mass self-immolation between the late 1600s and the early 1700s.

Sicarii at Masada

The most notable example of historic mass suicide, and the one whose narrative occupies a prominent and compelling place in both Jewish and non-Jewish heroic traditions, is the Sicarii mass suicide at Masada during their revolt against the Romans in 73 C.E. Josephus's account of the Sicarii resistance fits the aforementioned historic pattern of the use of mass suicide as an endgame political strategy for an oppressed group. The Sicarii, a group of Jewish resisters to Roman occupation, who were led by the charismatic Elazar Ben Ya'ir, occupied the Masada compound and defended it from a three-month siege by a Roman Legion. When the Roman army eventually overtook Masada, they found that the 936 inhabitants of Masada chose to die rather than to surrender as defeated prisoners.

The aforementioned examples, the Jauhar self-immolations of medieval India, the self-immolations of the Russian Old Believers of the 17th and 18th centuries, and the Sicarii martyrdom at Masada in 73 C.E., fit the pattern of suicide as political protest, eschatological endgame, and an act of collective insurgency. These historic examples also showcase the use of suicide as a Pyrrhic liberation strategy for subjugated social groups. While some contemporary mass suicides have expressly political motives, coupled with the collective mindset of being under siege by an outside power, as in the cases of The People's Temple mass suicide of 1978 or the Branch Davidians mass suicide of 1993, most cases are nonpolitical and religious in nature.

Contemporary Examples

The 20th century has witnessed some of the most ghastly spectacles of mass suicidal behavior. The spectacle nature exists because of the role that visual mediums, namely television and the Internet, play in popularizing massive deaths. The most notable case in point is the macabre television images of 913 decedents of Jim Jones's People's Temple in Guyana, November 18, 1978.

Jim Jones and his followers initially left the United States in 1977 with the goal of building a utopian religious community in the jungles of Guyana, but eventually ended their lives by ingesting a cyanide-laced drink in an act he referred to as "Revolutionary Suicide." Jim Jones believed that the People's Temple was besieged by the federal government, who was threatened by its utopian experiment and actively sought to arrest its leaders and put an end to its activities. This "Revolutionary Suicide" might be understood as a form of political protest against the government by a deranged charismatic leader and his disillusioned followers. Indeed, many of the contemporary examples of mass suicide were under the headship of charismatic religious cult leaders who had a history of psychosis: Jim Jones (The People's Temple), Marshall Applewhite (Higher Source, a.k.a., Heaven's Gate), and David Koresh (Branch Davidians) stand out as examples.

Contemporary examples of mass suicides, such as the Jonestown massacre, also comprise the mass murder of group members and outsiders, the former involving affiliates who may have opposed the idea of collective suicide, and the latter involving people who may have been perceived as being a threat to the group's cohesion and continued existence. Some other notable examples of this

phenomenon include the Movement for the Restoration of the Ten Commandments of God in Uganda, where over 700 members died in 2000 in an apocalyptic mass suicide/murder event while anticipating the end of the world; the Order of the Solar Temple, with 74 mass suicides/murders in Canada, Switzerland, and France from 1994 to 1997; and The Branch Davidians in Waco, Texas, with 76 mass suicide/murder decedents in 1993. These examples are cases where the mass suicides of adult cult members were coupled with the murder of children who, ostensibly, were not participants in the decision-making process and did not consent to suicide.

Cause

Some mass suicides occur because members feel themselves besieged and oppressed by society, as in the Jauhar suicides of medieval India, the Sicarii mass suicide at Masada, and the Russian Old Believers. It is external oppression that forces the group to employ suicide as a political strategy. These mass suicides are often an act of war. Other mass suicides, especially those involving religious cults, are driven by eschatological visions of a coming apocalypse and are *always* headed by a disillusioned charismatic. These proselytizing leaders convince true-believing adherents that mass suicide is a means to group salvation, and Heaven's Gate, the Branch Davidians, the People's Temple, and the Movement for the Restoration of the Ten Commandments of God are exemplars of the power of charismatic authority.

Other cases involve devotees who have a strong desire to follow a leader in death, as in the *junshi* suicides of Japan. In the junshi mass suicide, a leader's death provides an occasion for the most zealous devotees, who are now overtaken by intense bereavement, to follow their master in death. Yoshitomo Takahashi, as part of his analysis of junshi in modern Japan, describes a mass suicide by self-immolation that occurred in Wakayama Prefecture in 1986 following the death of Seiji Miyamoto, the founder of the Friend of the Truth Church. Seven of Miyamoto's closest adherents, who were determined to be with their religious teacher in the afterlife, died by self-immolation a few hours after his burial. Other types of mass suicides are compulsory or obligatory suicides during times of war, such as the *shudan jiketsu* mass suicides of civilians during the American invasion of Okinawa, or those of the legendary kamikaze pilots of Japan's Imperial Military at the end of World War II, who were ordered to commit mass suicide by turning their planes into flying bombs.

Typology

The mass suicide phenomenon would likely fall under the *fatalistic* or the *altruistic* forms in Émile Durkheim's sociological typology of suicide, although it is important to note that he did not specifically attend to the mass suicide in his 1897 study. The closest Durkheim comes to a description of the *mass* phenomenon is his chapter on imitation or cluster suicides. Nevertheless, Durkheim notes that the *fatalistic* suicide is a type that is caused by excessive social regulation where individuals feel themselves oppressed by society, and he cites the suicide of slaves as exemplars. Albert Black, in his seminal study of the Jonestown tragedy, using archival tape recordings of Jim Jones's own "sermons" in Guyana, concluded that most of these suicides were fatalistic. Likewise, the mass suicide and murder of the members of the Movement for the Restoration of the Ten Commandments of God was of the fatalistic variety.

On the other extreme, the *altruistic* suicide results from too much social integration, where the individual takes his or her life out of a deep sense of commitment or duty to the group. Lakshmi Vijayakumar, in his research on mass suicides in Medieval India, classifies Jauhar under this type. Similarly, Durkheim cites the sati of India, where widows end their lives through self-immolation upon their husbands' death, as the altruistic kind. Other altruistic mass suicides include the Junshi and Shudan Jiketsu suicides of Japan, especially the latter as seen in the kamikaze pilots of WWII.

Medical Examiner

In the United States alone there are over 3,100 counties that have more than 2,300 separate death investigation systems. The term medical examiner may refer to: a member of the state medical licensing body (the Board of Medical Examiners), a life insurance medical physical inspector (who may or may not be a physician), a physician in general, a coroner or similar death investigator (usually not a physician), or a forensic pathologist. For the purposes of this discussion, the term medical examiner is used to refer to the governmental physician employee specifically charged with the medicolegal investigation of deaths occurring in the jurisdiction.

The Evolution of a System of Medical Investigation

The societal interest in death investigation is longstanding. In fact, the function of medicolegal death investigator is the oldest judicial office in existence in Anglo-American law. More specifically the office of coroner (a corruption of the original "crowner") or *custos placitorum coronas,* the keeper of the pleas of the crown, is first documented in 1194 in the Articles of Eyre. However, the office dates even further to pre-Norman England circa 900. In Ancient China (ca. 475–221 B.C.E.), the government had an office charged with the function of medicolegal death investigation.

Although the original motivations for the creation of a death investigatory body are unknown, the reasons for this interest are many and have evolved with the passage of time. Originally, the function was primarily financial in attempting to maximize death-related revenues to the crown. Over time, the government's monetary interest faded as the information took on greater significance. The office of coroner immigrated to the colonies and continued much as it had in the United Kingdom. Gradually the medical aspect became more important and physicians became involved in the process, eventually giving rise to the medical specialty of forensic pathology and the office of the medical examiner.

Initiatives undertaken within the Northeastern United States were responsible for this gradual advance of the science of death investigation. Maryland was at the early forefront of professionalizing death investigation with the coroner permitted to require physician attendance at inquests as early as 1860. This was followed by an elected physician coroner position created in 1868 and physician medical examiners performing autopsies for the coroner in 1890. Massachusetts replaced coroners with physician medical examiners in 1877. The first medical examiner system, in the purest sense, began in New York City in 1918.

Over time, the need for increased professionalism became more apparent and the modern concept of medical examiner spread. Roughly every 15 to 20 years since 1928, the need for improved medicolegal death investigation is recognized at a national level. One of the most significant such analyses resulted in the creation of a Model Postmortem Examinations Act in 1954 by the Uniform Law Commission. The result was establishment of a plan for improved death investigation by a local implementation in interested communities of a functional plan. There ensued a flurry of activity and creation of many new medical examiner systems across the country up to about 1990,

at which time the movement toward improvement stalled at both the state and local levels.

At present, approximately one-half of the U.S. population (one-third of all counties) is served by a medical examiner system: 22 states have pure medical examiner systems without coroners, 14 states have mixed medical examiner/coroner systems, and 14 states have nonmedical examiner systems. Organizational oversight of the medical examiner death investigation office varies widely: 10% forensic laboratory, 14% health department, 33% public safety/law enforcement, and 43% other governmental office. The management niche occupied by the office of the medical examiner may seem trivial, but in fact it may be a major determinant of the focus of the office in how cases are accepted and which cases get major scrutiny as well as how funding is allocated.

Forensic Pathology

The forensic pathology specialty that embodies the ideals of professionalized medicolegal death investigation conducted by medical examiner is fairly new, having been recognized by the American Board of Medical Specialties in 1959. But the specialty is quite small; of the total 15,000 medical students in America, only 3% (500) continue their postgraduate medical training in the general field of pathology.

There are presently 39 accredited training programs in forensic pathology in the United States that put out fewer than 50 trained forensic pathologists each year. Since 1959, a total of 1,300 physicians have attained board certification in the discipline, and of those, only 400 are active full time. To illustrate the need for additional practitioners, that equates to 375 to 1,000 autopsies per medical examiner. National performance standards recommend no more than 250 autopsies be performed per forensic pathologist. Laboratory accreditation is not permitted for pathologists performing in excess of 325 to 350 autopsies each year.

Forensic Autopsy

The major tool employed by the medical examiner is the forensic autopsy. This differs from the conventional hospital/medical autopsy conducted by a general anatomic or hospital pathologist in significant ways. Generally, the medical examiner is empowered by law to conduct an examination, the extent of which is determined by the medical judgment of the forensic pathologist, in order to determine the cause and manner of death. The general pathologist, on the other hand, receives permission from the decedent's legal next of kin to conduct an examination, the scope of which may be limited by the requestor to as little as one organ, which may not even be allowed to be removed from the body. The medical examiner is involved in determining how and why an unnatural death occurred, while the hospital pathologist is generally involved in elucidating the mechanisms involved in natural deaths in order to address clinician questions relating to disease.

In addition to the visual examination of the tissues of the body at the macroscopic (gross pathology) and/or cellular level (histopathology), the forensic autopsy may employ numerous specialized procedures, most often including toxicology testing, specialized chemistry, metabolic disease testing, and microbiology cultures. Not all examinations require every test, and clinical judgment includes or excludes certain tests. The prudent practitioner considers not only the physical examination, but also the case history of past medical events and perimortem circumstances, as well as clinical data derived from review of the patient's medical record and clinical course immediately prior to death.

All of the case information is ideally considered prospectively and retrospectively as superimposed on the context of the scene of death. All death investigations begin at the scene and a great many shortcomings may be traced to inadequate scene documentation and/or procedures. Such basic questions as estimated time of death are best addressed by a knowledgeable examiner conducting a physical assessment of the body as found at the scene as soon as possible—the passage of time broadens the window of the estimate and allows less precision.

Issues Related to Duties of the Office

Regardless of the overall governmental niche occupied, the medical examiner must be functionally independent of other agencies and processes such that the medicolegal conclusions reached may not

be influenced or reasonably perceived to have been influenced by individuals with an agenda that is contrary to the impartial, scientific determination of the circumstances surrounding a death. In addition to system limits, significant differences exist between practitioners. In the end, the final determination of the cause and manner of death by a medical examiner are professional opinions, based on available information as filtered through the lens of years of training and experience, and may be held to different levels of certainty, either reasonable probability or reasonable certainty. One might criticize an autopsy for acts of commission but more frequently cited are omissions during the course of the original exam. A recent trend has been lawsuits attempting to limit the medical examiner's authority to retain tissues/organs deemed necessary for an appropriate diagnosis, which is the whole purpose of the autopsy. Equally troubling have been legal efforts to remove an established cause and/or manner of death, over the objections of the medical examiner, because someone was not pleased with the answer(s) provided.

System Commonalities

Although the systems vary by jurisdiction, there are some commonalities. All death investigations are controlled at the state level; however, the extent of this control varies. A properly functioning system deals with numerous societal concerns, including multiple and often overlapping roles—medical, public health, and justice—within the criminal and civil courts. At the core, the system is driven by the cases investigated, which is fairly uniform. The broadest definition includes cases involving sudden, unnatural, unexpected, or unexplained death and/or injury and those without a physician in attendance.

Additional specifics mandated by some jurisdictions include deaths associated with known or suspected poisoning, unusual or suspicious circumstances, environmental conditions, workplace events, police custody or involving law enforcement, public health concerns, and medical procedures/anesthesia use. A recent trend has been that deaths of juveniles, especially the very young, have special, legally mandated scrutiny. The ideal would be that all death cases would be adequately investigated with a minority of fatalities requiring further scrutiny by a medical examiner. In practice, this is often not the case. The cases that are too often overlooked are those deemed obvious by the inexperienced. Regrettably, these cases include elder and infant deaths where abusive trauma may have been involved. Another area neglected are homicides masquerading as apparent suicides or even natural deaths, written off based on inadequate investigation and lack of suspicion by those responsible for determining the true nature of the case.

Simply because a death falls under the legal requirement for medical examiner jurisdiction does not necessarily mandate the extent of such examination. The medical examiner will make such decisions based on many factors, including available resources, legal requirements, best practices, and local custom. For example, in some areas, religious objections to an examination may supersede the medical examiner's authority to take jurisdiction of the case and/or set limits for the procedure. Thus, specific religious proscriptions may operate to prevent an autopsy from being conducted. Likewise, an individual office may decide that all witnessed gunshot wound suicides are not worthy of more thorough analysis. In some areas, not even all homicide deaths require autopsy examination—in short, for myriad reasons, there are no national standard operating procedures in place.

Standards of Practice and Law

Despite establishment of national practice standards by professional medicolegal death investigation practitioners in 2003, less than 60 death investigation offices in the United States are accredited by the National Association of Medical Examiners. This demonstrates a lack of sufficient minimum resources, personnel, and procedures to attain such recognition. One of the major shortcomings has to do with insufficient personnel to handle the jurisdiction's investigative caseload.

Death Investigation

Death investigation cases fall into one of two broad groups—natural (seemingly self-evident) and unnatural (accident, suicide, homicide, and undetermined). In the United States, over 150,000 deaths are certified as unnatural each year. This number may not be accurate due to variability inherent in

the investigative system. A more accurate estimate for the need of proper death investigation may be derived form the statistic that ~1% of large populations can be expected to die each year; of all deaths, ~10% to 20% (highly variable) require professional investigation with roughly half to two thirds requiring autopsy examination. Therefore, based on a total 300,000,000 U.S. population, there will be 3,000,000 deaths per annum. Of these cases 300,000 to 600,000 should be investigated and of those, 150,000 to 400,000 autopsied.

Medicalization of Death and Dying

Medicalization of the dying is a form of medical treatment that concentrates on reducing the patient's pain and suffering. It does not delay or speed up the progression of death. However, high-quality, end-of-life care is limited, and most of the extant literature focuses on patients with cancer, thereby limiting the prospects for addressing the many important aspects of end-of-life care. This is noted in that hospice organizations serve most Americans dying of cancer and only 10% of all others.

History

Medicalization of the dying patient is a part of palliative care or hospice care. The concept of hospice is both a philosophy and a specialization that has important historical characteristics that are traceable to the Middle Ages, when in its embryonic form, life-rendering assistance was provided to those who engaged in the pilgrimage to the Holy Land. In the latter portion of the 19th century, a religious order of nuns established a hospice hospital for the dying in Dublin, Ireland, and then later in London, England.

The modern hospice movement originated in the United Kingdom after the founding of St. Christopher's Hospice in 1967 by Dame Ciceley Saunders. Training as a nurse and social worker sensitized Dame Saunders to what she observed and referred to as the patients' total suffering. The intensity of her observations of dying patients and the desire to assist them prompted her to pursue studies that ultimately led to a medical degree, after which she aggressively worked on behalf of pain-suffering patients on the verge of dying.

Hospice care in the United States, which began as volunteer-led movement, has evolved into a significant part of the health care system. From the initial hospital-based palliative care programs that began in the late 1980s, more than 1.2 million individuals and their families received hospice care during 2005. Much hospice care is delivered at the patients' home, but hospice care is also available in home-like hospice residences, nursing homes, assisted living facilities, veterans' facilities, hospitals, as well as prisons.

Symptoms

Patients with serious illness at the end of life should be regularly evaluated by clinicians for pain, breathlessness, anxiety, and depression. Each one of these

symptoms can be treated with separate medications, as per palliative care protocols. Following is a short overview of the medications used to treat intractable breathlessness, anxiety, and fear.

Pain

Patients at the end of life are generally receiving treatments effective in managing pain. For patients with cancer, such therapies include nonsteroidal anti-inflammatory drugs, opioids, and bisphosphonates. The available evidence is that the prevalence of pain is high in more than 50% in all cancer types, with the highest prevalence in head and neck cancer patients at 70%. More than one-third of the patients with pain grade their pain as moderate or severe. The World Health Organization (WHO) introduced a pain scale in 1986 that has been widely accepted. Combined with information pertaining to appropriate dosage guidelines, the scale offers sufficient evidence for clinicians to adequately access and implement adequate pain relief in 70% to 90% of all cancer patients. Yet, despite these clear WHO guidelines, the pain problem has yet to be resolved. More recent studies on the prevalence of pain in patients with cancer are still high, ranging from 24% to 60% in patients on active anticancer treatment to 62% to 86% in patients with advanced cancer.

Breathlessness

Patients with serious illness at the end of life should be treated to effectively manage breathlessness. These therapies include opioids in patients with unrelieved breathlessness, as well as oxygen for short-term relief of hypoxemia. Although beta-agonists may be useful to treat breathlessness associated with chronic obstructive pulmonary disease, this indication has not been studied for end-of-life care.

Breathlessness is often the most difficult to treat. Intractable breathlessness is one of the most common symptoms of end-stage cancer. The severity of breathlessness in patients with cancer increases greatly as death approaches. Palliative care was found to only be partially successful in alleviating it. Patients have suffered from breathlessness with minimal medical or nursing assistance. As much as palliative care can treat pain, there have not been the same therapeutic advances for the treatment of breathlessness.

Many studies show that breathlessness in advanced cancer depends on many different factors, most of which are irreversible. However, it was shown by the studies that a relatively small improvement in a number of different parameters (for example, treatment of pleural effusion or anemia, coupled with reduction in the patient's anxiety and support for the caregiver) may give relief. Research has also shown that it might be most effective to introduce anxiety-reduction training for patients early in the course of managing cancer and breathlessness as the disease advances.

Treatments of Choice

Data show that oral and nebulized opioids are effective in treating breathlessness, but to date this evidence is derived from noncancer cases. According to the latest guidelines, opioids are key to breathlessness control.

Literature suggests that both oxygen and air can alleviate breathlessness in patients with cancer. The relief was seen not as much as a result of the correction of low oxygen in blood, but rather as a result of the flow of gas. Patients with insufficient oxygen in their blood may not be breathless. And even if patients are both low on oxygen and breathless, correcting the oxygen level in patient's blood does not necessarily make their breathing easier.

Helium is less dense than air. When mixed with oxygen, it replaces nitrogen in air and reduces turbulent flow in narrowed airways. Thus, it reduces the work of breathing and improves ventilation inside the smallest lung passages—the alveoli. There is one study of the effect of heliox versus oxygen-enriched air in 12 patients with lung cancer and breathlessness on exertion. Heliox 28 (72% helium and 28% oxygen) reduced breathlessness on exertion and increased both exercise capacity and oxygen saturation, both at rest and during exertion.

A number of trials of inhaled furosemide have indicated that it may relieve breathlessness in terminal cancer patients. Furosemide is a commonly prescribed loop diuretic. When inhaled as a mist, furosemide has various actions on lung tissues that inhibit cough and protect against bronchoconstrictor stimuli. However, these actions do not fully explain breathlessness relief in the absence of asthma or other lung diseases.

Phenothiazines are preferred when sedation or anxiolysis is needed in severe breathlessness. A low dose can be added for patients still experiencing intrusive anxiety.

The use of benzodiazepines in the treatment of breathlessness is less supported in the literature than that of phenothiazines. Phenothiazines may be the drug of choice when the patient's fear is out of control at the end of life. If fear, instead of anxiety, is the primary concern of the dying patient, the addition or substitution of levomepromazine or haloperidol is frequently recommended.

Depression

End-of-life depression treatment studies primarily focus on cancer patients. Tricyclic antidepressants and selective serotonin reuptake inhibitors are uniformly effective, given sufficient treatment duration. Studies also report that education, cognitive and noncognitive behavioral therapy, informational interventions, and individual and group support are beneficial. Although palliative care does not seem to improve depression per se, such care does seem to improve the patients' spiritual well-being.

One Treatment for All

The preferred form of medicalization in dying patients is continuous, deep sedation with benzodiazepines, used to control all of the patient's symptoms. In this case, breathlessness, pain, anxiety, and fear are all taken care of by the continuous administration of one medication. Authors point out that palliative care is personalized and costly, while continuous sedation is a relatively inexpensive, one-size-fits-all treatment. Also considering that most of the hospice care is still administered by general medicine doctors, and not by palliative care certified specialists, continuous sedation represents a simple method of addressing the different aspects of patient's suffering. Sedation is increasingly considered as part of regular medical practice among United States and United Kingdom physicians treating terminally ill patients who are close to death. However, with this uniform treatment, sedation may be used as a substitute for meticulous assessment and intensive treatment of physical symptoms and psychological or spiritual distress.

Medical Malpractice

Death is a normal and inevitable part of the human experience. Under the physician's hand, death is a regular occurrence, as these practitioners strive to ward it off for us, for example, in critical care surgery. It is physicians who certify death, and their close relationship to this final stage of the human experience contributes to their status. However, death *by* a physician's hand, due to negligence, strikes at the heart of the Hippocratic oath: "first, do no harm." An instance in which a physician causes injury or death to a patient through negligent behavior is called medical malpractice. Negligence is action that fails to follow acceptable standards of practice. Estimates of deaths resulting from negligence are unreliable, ranging from the low thousands to the high hundreds of thousands per year, depending on who is counting and how broadly negligence is defined. Malpractice is consequential not only for the welfare of patients, but also for the professional status of physicians and the trust the public bestows upon them. Medical injuries, medical errors, negligence, and malpractice claims are complex phenomena, involving the legal tort system, the economics of health and liability insurance industries, the risk-management industry, consumerism, the patient-doctor relationship, the status of health professions, political stakeholders, the welfare of the population, and the ambiguities of death and dying.

Distinguishing Negligent From Normal Injury and Death

Medical malpractice claims arise from adverse health *outcomes* that occur under the care of a physician. If a physician is negligent but causes no injury, then there will likely be no claim. It is the effects of injury, including psychological injury to survivors of a wrongful death, that serves as the basis for monetary settlements. When an injury occurs, a malpractice claim is an assertion that it was caused by misdiagnoses, poor mastery of treatment standards, or observable practitioner error. However, medical complexity and uncertainty make establishing negligence difficult. Deaths and injury (e.g., the surgeon's cut) are a normal part of medical practice and life. Less than 20% of malpractice claims are *res ipsa loquitur* cases, those that "speak for themselves," such as mistaken amputation of a healthy limb. In the remaining cases, it is difficult to discern a normal adverse event from preventable medical error. This ambiguity leaves the process of determining what really caused an adverse outcome to variable interpretations. As a result, stakeholders other than doctors have a say in constructing and interpreting the facts within the context of an adversarial civil law (or tort) system. Especially for an untimely death (e.g., an infant), aggrieved survivors may seek justice for economic and psychological costs. Medical uncertainty means that negligence is continuously redefined in the evolution of tort law as well as in the medical arena itself.

Medical uncertainty is reflected in summary statistics on the incidence of avoidable medical injuries, adverse outcomes, medical errors, and malpractice claims. Data on malpractice claims (legal facts) and medical error (a frequently ambiguous assessment) are skewed by assorted stakeholders, including claimants, defendants, physicians, hospitals, trial lawyers, medical liability insurance companies, and patient advocacy groups, all of whom use different operational definitions of injury and negligence. Physician estimates focus on *res ipsa loquitur* cases and exclude systemic errors, such as poor infection control in hospitals. Their estimates of malpractice-caused deaths per year are in the low thousands (e.g., 6,000–12,000). Estimates by legal interests define practitioner-caused mortality broadly and include systemic errors. Their estimates are as high as 780,000, about one-third of all deaths, making medical errors and negligence a top-three cause of death. Even objective researchers must make assumptions that favor one or another stakeholder. Statistical analysis of malpractice is complicated further by varied litigation processes; distinguishing injuries and adverse outcomes, claims, and lawsuits; active and disposed cases; out-of-court settlements and jury verdicts; and jury and actual monetary awards. These legal processes vary somewhat by state and court jurisdiction.

Regardless of a claim's resolution, real negligence may or may not have occurred. Nonetheless, claims data are posed as indicators of the occurrence of malpractice.

While an objective assessment of medical negligence is hampered by the complexities of medicine and the politics of stakeholders, the uncertainty of medical practice assures that many injuries and deaths occur from undetected negligence and go unclaimed. And timely deaths, such as with elderly people, often are not scrutinized.

The Legal Context of Malpractice Claims

Notwithstanding the complexities of identifying true negligence, enough physicians have incurred claims that it is no longer a surprising event, especially for obstetricians and surgeons. Over half of all physicians have incurred a claim at some time in their careers. Many State Boards of Medical Examiners and consumer groups post claims histories on the Internet.

While negligent physicians most assuredly have always existed, an increase in malpractice claims is a relatively recent phenomenon, reaching public knowledge in the early 1970s. Historical changes in medicine, law, and society are posited to explain what amounted to an abrupt increase in claims and settlement costs. This surge of cases followed changes in tort law allowing patient-claimant attorneys to use expert witnesses from outside the local community. Physician defendants then had to show adherence to national rather than local standards and answer to other than their colleagues in the local medical society. An increase in just a few high-dollar claims created a financial "malpractice crisis" by the mid-1970s, characterized by inflation of medical liability insurance premiums. In some states, such as California, Maryland, New York, Ohio, and Texas, medical liability premiums jumped fivefold in one year. Since that time, periodic financial crises have occurred with cyclical downturns in the stock market. When liability insurance company stocks drop in earning value, it requires adjustments in liability insurance premiums to cover anticipated malpractice losses. Whether increases in malpractice cases are due to more negligence or to changes in tort law is unclear; however, the rapid increase of all types of litigation in the United States suggests the reason is change in tort law.

The Financial Impact of Malpractice Litigation

From an economic standpoint, some medical inflation results from malpractice settlements and premium costs. Mere physician fear of litigation incurs costs, as physicians seek to avoid claims. Risk-reduction is now a standard practice, and defensive medicine—physicians ordering extra tests, second opinions, and referrals to high cost specialists for fear that records may be scrutinized in court—has become institutionalized. What was once called defensive medicine is now seen as *more thorough care*. At least for patients with comprehensive access, this care has resulted in some cost inflation, although the extent of it is debated among stakeholders. In state governments, where health legislation resides, business interests, such as professional physician groups, hospitals, medical liability insurance firms, health insurance companies, and the corporations that pay employee premiums, typically spar with trail lawyers and consumer rights groups. Business interests partly blame malpractice litigation for recent health care cost inflation, reductions in health care access, and a growing uninsured population. Some states have capped jury awards for pain and suffering, but the effect of this legislation on overall costs is disputable.

The Impact on the Quality of Care

Notwithstanding the fact that much defensive medicine is medically unnecessary, from a patient-welfare perspective, a case may be made that, for those with access to health care, the quality of care is enhanced by the implicit accountability inherent in malpractice tort law. Strathern's concept of audit culture explains some of the increase in litigation. An audit culture is part of the corporatization of all aspects of the economy including health care. In an evolving audit culture, organizations and individuals are increasingly being held to account and subjected to economic as well as behavioral audits, such as performance evaluations. Job performance is assessed with scorecards that require setting benchmarks. The idea of an audit carries with it assumptions that job tasks have rational certainty with clear causal paths from actions to outcomes and that actions can be accurately measured. Such rational assumptions run head-on into the inevitability of death, and the uncertainty of

medical tasks and the practitioner autonomy they require. Physicians plead for trust in professional judgment, while auditors, such as hospital review boards, health maintenance organizations, and tort lawyers, want a full accounting. From the physician's standpoint, these are extraneous forces, but they are legally and morally powerful. To argue against an audit is to stand for soft standards and privilege. Resistance to audits implies that there is something to hide, and that a practitioner is not only incompetent but also dishonest. Furthermore, the philosophical context of audit culture carries with it moral undertones that demand punitive resolutions for less than stellar audits. When a physician not only fails to meet a goal but also causes avoidable harm or death to a patient, this constitutes an unfair economic transaction *and* a moral breach of trust. Moreover, consistent with the accounting practice of focusing on the bottom line, audits tend to center on *outcomes* rather than process. As a result, even an untoward treatment outcome unrelated to physician behavior, such as an unavoidable childbirth death, may nonetheless incur a charge of negligence. From a family's perspective, it is not supposed to happen. In an accountability-oriented society, medical uncertainty must coexist with the highly valued ideal of calculated, auditable certainty and moral certitude.

Sociological Perspectives on the Malpractice Crisis

A sociological way to conceive of the malpractice trend of the past four decades is from the perspective of medical rationalization. This approach combines the processes of audit culture and corporatization with larger change processes, such as the medicalization and biomedicalization of society and rapid medical innovation and its implications for patient-physician interaction and trust. The most obvious aspect of rationalization is an increase in formality, stricter standards and rules that guide a practitioner's actions. This is a focus not so much on the outcome of work, but the structure and process of working. For physicians, it involves a transition from a highly autonomous practice style to one that has traces of production line work. For example, mandated risk-management procedures in hospitals force physicians to follow risk-assessed protocols, to accept peer review, and to relinquish certain tasks to other physician specialists and health practitioners. Rationalization is systemic. For example, liability insurance carriers set premium charges according to medical specialty and require specialty certification. As a result, clearer delineations of task boundaries among physician specialists occurred rather rapidly after the initial malpractice crisis in the mid-1970s. The medical malpractice crisis is an instance of two institutions, medicine and law, becoming intermingled. The highly rational structure of law is superimposed on the highly uncertain institution of medicine. While many outcomes of this phenomenon may be positive, such as an increase in accountability and medical care quality, many unintended irrationalities are likely to occur. Fear of litigation influences patient–practitioner interaction in both positive and negative ways. The medical malpractice crisis is part of a larger patient's rights movement, which many health ethicists view as a positive phenomenon that enhances the quality of care. On the other hand, physician fear of malpractice litigation encourages stereotypes of *suit-prone* patients, who may be treated differentially.

Malpractice issues also inform theories of medical deprofessionalization and countervailing powers, concepts that challenge notions of professional medical dominance. Finally, there is literature on differences in how stakeholders view the issue, especially physicians and lawyers.

Medical Mistakes

Medical mistakes, or medical errors as they are called in research literature, are terms that defy easy definitions. In a widely cited report on adverse medical outcomes titled *To Err Is Human: Building a Safer Health System*, Kohn, Corrigan, and Donaldson of the Institute of Medicine (IOM) define medical error as the failure to achieve an intended goal either because of a failed initiative or a plan of action that is ill conceived.

This means that errors can occur in execution, in planning, and at all stages of practitioner–patient interaction. There is a wide range of medical errors, including failure to diagnose, misdiagnosis, and late diagnosis; drug prescription and administration errors, and failure to foresee adverse reactions among multiple prescriptions; over-, under-, and misprescribing of medications; surgical and procedural errors; overuse of diagnostic tests and surgical procedures, such as Caesarian sections; mistakes in choice of intravenous (IV) solutions, their concentrations, and drip rates; mishandling of medical records and test results; and failure of aseptic procedures resulting in spread of infections in hospitals. However, it is important to be mindful that injuries, such as surgical cuts and adverse outcomes, such as medication side effects, are expected to have a certain occurrence. In risk assessments, as long as a treatment does more good than harm, a rate of occurrence of side effects is deemed acceptable. However, if an unusual injury or adverse outcome occurs where a risk assessment is unclear, regardless of whether it was preventable or due to practitioner negligence, the event may appear as error. Thus, studies of medical errors often define them as adverse events that could have been prevented.

The complexities of the previous definitions reveal that identifying medical error is itself fraught with potential error. With injury being a normal part of surgery, and treatment often incurring side effects, distinguishing normality from error is difficult. The IOM report describes in detail the multidimensional nature of errors and the challenges of identifying and preventing them. In fact, the IOM report's main impetus is a call to apply to medical settings the standard safety and risk management practices found in other industries that place people at risk, such as the airline industry. The emphasis is on safety and the prevention of adverse events through systemic changes in organizational procedures and professional culture. If an adverse event can be avoided, whether or not the treatment process included errors is a moot issue.

However, the practice of medicine is distinct from other industries. Medical care is about trying to save people as well as keeping them safe. For example, in hospital care even the extreme outcome of death is normal. In contrast, in most other industries, even those that are risky such as airlines and mining, there is no justification for a death. Error and risk assessments in medical care delivery occur in the context of biomedical complexity, esoteric knowledge, and the resulting uncertainty of medical practice. Notwithstanding periodic fluctuations in occupational prestige, medical practice has professional components that make it distinct from industrial work. Medical practitioners are allowed a degree of professional autonomy that overrules and sometimes conflicts with the formal rationality of typical production bureaucracies. This means that what constitutes error depends on what constitutes standard procedures, but many such procedures are necessarily elastic. Medical practice standards are normative. They depend, at a particular time in history, on a society's level of medical and organizational knowledge, its resources, and its epidemiology, including socially produced mortality and morbidity.

Furthermore, patients bring assorted risks with them. Patient ailments and the procedures applied to remedy them carry variable levels of risk for adverse outcomes. Each patient's condition varies according to presenting symptoms, which depend on age, health, functional capacity, propensity to certain illnesses, severity of condition, comorbidity, and the ability to clearly communicate. Moreover, treatment regimens, patient adherence, and biological and psychosocial reactions to treatment depend on a similar assortment of personal variables.

Herein the term *medical actions* refers to all aspects of diagnosis and treatment, including decisions, clerical actions, analysis of test results, prescription of treatment, manual treatments such as surgery, and communication with patients and other practitioners. From the practitioner side, there are individual, systemic (i.e., part of organizational structure), and circumstantial variables

that influence medical actions and the likelihood of a patient incurring an adverse outcome. Individual factors include (a) overall practitioner competency (e.g., training, certification, expertise, years of experience), which can cause mistakes in the choice of medical action; and (b) typical human error, what Reason (1990) calls a slip or lapse, a correct choice of action but poor execution due to the "human element." Systemic factors are those related to the standard formal operating procedures of a medical organization as well as its organizational culture, which includes informal norms and procedures tied to professional authority. These factors include (a) the medical protocols of a hospital; (b) quality control and risk aversion procedures, such as procedural checklists and mortality and morbidity review committees; (c) type and efficiency of health information and prescribing systems (e.g., reliance on paper or electronic records); (d) efficient and safe division of labor, for example, appropriate integration and use of assisting practitioners, such as clinical pharmacists; and (e) quality of working relationships among practitioners and other staff. Circumstantial factors that can increase risk of medical error include (a) distractions and strains in work settings (e.g., a rush on a hospital emergency room due to a tragic event) and (b) personnel staffing issues, such as a shortage of nurses or other practitioners, serving too many patients, covering too many places at once, or working long hours.

The multidimensional features of medical error are apparent in a number of ways. First, it is critical to determine whether medical error did in fact occur. Second, it is important to determine whether corrective actions were taken. A third issue pertains to whether an error was detected. Many errors occur but go unnoticed. Fourth, if an error was detected, it may or may not have been brought to anyone's attention or reported to the patient or organizational authorities. An alleged error in treatment is unlikely to be acknowledged and reported unless it was consequential for the patient's prognosis and revealed in an adverse outcome. A fifth issue is whether an adverse outcome could have been avoided. Many adverse outcomes occur despite the remedies applied and despite whether those remedies follow standard practices. For example, a 90-year-old man dying of cardiac failure during hip surgery is a calculable risk, and this adverse event happens when standard or even state-of-the art procedures are followed. Irrespective of whether an error occurs in these types of situations, it might be attributed to known risk and spelled out ahead of time in informed consent papers. The multidimensional nature of medical error means that assessments of it are seldom straightforward. Even for alleged medical errors that evoke malpractice suits, only about one in six are indisputably determined to result from practitioner negligence. The questions of error and negligence usually evolve around the occurrence of an adverse outcome and whether it could have been prevented. But medical "preventability" is stochastic; that is, risks occur with a probability. These perplexities reveal the difficulties of identifying and analyzing medical errors, and this is reflected in the large range of statistical estimation error for reported incidences.

The Incidence of Medical Error

The IOM report gained widespread coverage because of its notable statistics on the incidence of preventable deaths attributed to medical errors. Estimates were based on a thorough analysis of two hospitals. After extrapolating the data to all U.S. hospitals, the authors concluded that between 44,000 and 98,000 Americans die each year because of medical errors, representing about 3% of all hospital admissions. These estimates shocked the public, especially since many medical errors go unreported. In the aftermath of the IOM report, research on medical error greatly increased. Much research attempted to refine estimates with some disputing the high estimates of the IOM report. Others affirmed the IOM estimates or even suggested that these estimates were low. However, medical error was operationalized in assorted ways and many studies tended to focus on one type of adverse event, such as hospital infections.

Two things are clear from the research on medical error. First, it is impossible to establish a consensus on what constitutes medical error, how it is to be operationalized, and the reliability of extrapolated estimates. Second, notwithstanding measurement challenges, preventable medical error occurs at unacceptable rates and more research is warranted on how to reduce it. The IOM report and subsequent research is refocusing the

discussion to the issue of patient safety, with the intent of not only preventing medical error, but also enhancing care quality.

Making the Health Care System Safer

As the IOM report notes, error is prevented when the health care process is made safer. The IOM report, the Agency for Healthcare Research and Quality (AHRQ), and a multitude of researchers propose the following systemic changes: infection control measures, electronic record keeping and computer entry of physician orders to reduce prescription errors and enhance communication among practitioners, health team training and use of protocol checklists, workshops and knowledge dissemination on established best practices, and increased grant funding for patient safety research.

The IOM report criticizes punitive approaches that seek to prevent medical error by scrutinizing individual human error. Instead, it emphasizes that error prevention requires correction of the systems and contexts in which medical work occurs. But despite calls for systemic changes in the report, recent researchers continue to lament the strong tendency for punitive, individualistic remedies. Public and political interests are slow to view patient safety as a complex systemic problem requiring scientific analysis. It is too easy to view system failures as simply bad doctoring, and this narrow perspective leads to a simple solution: Remove the bad doctors and the problem will be solved. There is even outright resistance to an emphasis on systems. Not blaming individuals for errors is viewed as subterfuge, an attempt by powerful doctors and hospitals to hide the problem. As a result, legislation typically calls for stricter reporting requirements for physicians and hospitals to expose wrongdoers and hold them accountable. Fixing blame takes precedence over improving patient safety through preventive measures. This preoccupation with individual responsibility and personal accountability guides legislation on this issue as it does on most social legislation in the United States.

Advocates for systemic change do not disregard personal accountability. Full disclosure of medical errors to patients, hospitals, and third parties is a persistent issue. Research continues on systemic changes in patient safety, but advocates of the issue seek greater grant funding. Systemic change requires more than a change in the professional and shop floor cultures of medical settings. It requires cooperation among multiple federal agencies, professional associations, state and federal governments, hospital associations, and patient-advocacy groups. Medical error is a sociopolitical as well as biomedical issue.

Megadeath and Nuclear Annihilation

Nuclear and thermonuclear weapons, two terms that are used interchangeably, constitute a preventable cause of mass megadeaths. Actual mortality

data (number and rates of deaths), resulting from the Hiroshima and Nagasaki atomic bomb detonations in 1945 and projected mortality data from contemporary nuclear war scenarios will be addressed. Efforts to prevent nuclear war and proliferation of nuclear components and weapons are also discussed.

H. G. Wells in his novel, *The World Set Free*, published in 1914, predicted a fictional war in 1956 where atomic bombs exploded continuously for days. The weapons were eagerly sought by malcontents and others. In 2007, 93 years later, the Board of Directors of *The Bulletin of the Atomic Scientists* moved the minute hand of its symbolic Doomsday Clock from 7 to 5 minutes to midnight signifying the increased prospect of nuclear war. Buyers and thieves avidly seek nuclear weapons on the open market. Science fiction becomes reality.

So far the Hiroshima and Nagasaki bombs have been the only nuclear weapons intentionally used in warfare. But since then, the destructive power of nuclear (fission) and thermonuclear (fission-fusion) weapons and their delivery systems have dramatically increased. During the cold war, the United States and the Soviet Union had a monopoly on the nuclear bomb market. Today, nuclear states include the United States, Russia, the United Kingdom, France, China, India, Pakistan, North Korea, and possibly Israel. Thirty-two other nations, including Brazil, Argentina, Japan, South Korea, Taiwan, and perhaps, Iran, have sufficient fissionable materials to produce weapons. Not all will seek them. Hardware, fissile material, and the knowledge for constructing weapons are available at the international arms bazaar and on the Internet. As their availability increases, so does the probability of accidental or intentional nuclear weapons detonation, and with it, the prospect of megadeaths, megadying, and megasuffering.

Because of security issues and variations in assessment methods, public data are not totally reliable. However, exact figures are not necessary to illustrate the destructive capability of nuclear weapons. Risk assessments of nuclear war make little sense because the quality and quantity of any retaliatory response is difficult to predict. Only one detonation is necessary to elicit a large, unpredictable nuclear response that might include the use of other weapons of mass destruction (i.e., biological and chemical agents). Nuclear weapons detonation has the potential of omnicide (destruction of humanity by humanity) resulting in megadeath (deaths of people and animals in the millions). It is a form of horrendous death (HD), that is, deaths caused by people. One type of HD is motivated by the desire to kill others. Examples of this desire that could kill millions are intentional environmental assault, terrorism and war, genocide, starvation, use of biological and chemical warfare agents, and the intentional spread of deadly diseases, including new immerging and antibiotic-resistant diseases. Omnicide and HD affect large populations and entail great suffering. Both are preventable.

The First Atomic Bombs: Hiroshima and Nagasaki

On August 6 and 9, 1945, two fission-type bombs were dropped that effectively ended the war with Japan. The first bomb detonated over Hiroshima had an estimated yield of 15 kilotons (KT), equivalent to 15,000 tons of TNT. Its fuel was highly enriched uranium 235 (HEU). The Nagasaki bomb, powered by plutonium 239, had an estimated yield of 21 KT, equivalent to 21,000 tons of TNT. Both were fission-type bombs.

The estimated number of deaths, reported in 1945 following the Hiroshima detonation, was 140,000 or more. The Nagasaki death count for the same period was estimated at 40,000 to 70,000 or more. Most people close to the epicenter died instantly. Many who were further away died of trauma, burns, and/or radiation effects. Long-term deaths were estimated at around 119,000 to 140,000.

Today's Inventory of Nuclear Weapons and Their Capabilities

Today's thermonuclear bombs (combining fission and fusion) have yields measured in megatons (one megaton equals approximately 1 million tons of TNT), and are many times more powerful than fission-type weapons. The average nuclear weapon in the United States is approximately eight times more powerful than the nuclear bomb that destroyed Hiroshima. Yields range from low, used to destroy specific small targets such as buildings and electric power stations, to Russia's big yield of 50 megatons.

Estimates are that about 26,000 to 30,000 nuclear warheads are stockpiled in the world. The United States and Russia possess about 95% of these. As of 2007, the U.S. stockpile contained nearly 10,000 warheads. Russia has about 16,000, France 300, Great Britain and China 200 each, Israel 75 to 200, India 45 to 50, and Pakistan 24 to 48. Of these about 13,000 are deployed and 4,600 of these are on high alert; that is, these are ready to be launched within a few minutes' notice. The combined yield of these weapons is approximately 200,000 times the yield of the Hiroshima fission bomb. Approximately 2 million kilograms of HEU are in global stockpiles. HEU provides the fuel for atomic weapons, nuclear power plants, and nuclear reactors. Plutonium is derived from it and used in fusion-type bombs.

Weapons are now more efficient. Some combine conventional explosives with high radioactivity (i.e., dirty bombs or radiological dispersion devices) and can be carried in backpacks. The Multiple Independently Targeted Vehicles (MIRVs) carry several nuclear weapons and may be delivered by an intercontinental ballistic missile (ICBM) or submarine-launched ballistic missile (SLBM). Such weapons can strike several targets simultaneously. Some weapons are designed to destroy the physical infrastructure, including bunkers and tunnels, where an enemy might hide. The neutron or cobalt bomb is a small thermonuclear bomb that produces minimal blast and heat but releases high amounts of radiation.

Underestimating the Mortality Effects of Nuclear Bomb Detonation

The killing effect of nuclear weapons, including the devastation caused by blast, thermal radiation, and mass fires, are underestimated. That combination is more deadly than blast effects alone. Also underestimated are the health hazards of ionizing radiation. It was only in the 1970s that governments and scientists became aware of risks to the ozone layer.

Radiation contamination from nuclear weapon explosions could linger for years. One study predicted that the detonation of a single one kiloton nuclear weapon on the surface of Detroit during a workday would kill 130,000 people within a 27-mile radius. It would take a minimum of 8 years to return to background levels of radiation assuming no decontamination effort.

Preparation Tactics and Preventive Strategies

Preparation tactics and related programs come into play before or directly after an attack. In the United States, the Department of Homeland Security, the Centers for Disease Control and Prevention, the Federal Aviation Administration, state and local departments of public health, fire and police departments, and others are some of the agencies responsible for preparation. Assessments and field tests show that hospitals, the public health establishment, and other first responders are inadequately prepared to deal with the complex, long-range aftermath of an attack.

Preventive nuclear strategies and processes evolve over time. But suspicion and distrust within and between states are common and increase the possibility of nuclear war. Most bilateral and multilateral policies and treaties designed to prevent acquisition or proliferation of weapons or weapon materials include aspects of surveillance, early detection, verification, and subsequent remediation of the situation. Another mantra is "Trust but verify."

Following World War II and during the cold war with the Soviet Union, Mutual Assured Destruction (MAD) was the dominant strategy of deterrence. It promised massive retaliation. Eventually the Soviet Union and the United States realized that there would be no winner in a nuclear war. Still, MAD remains the dominant preventive strategy.

In 2002, a modified MAD doctrine took the offense. The administration of U.S. President George W. Bush adopted the doctrine of preemptive attack as described in the National Security Strategy of 2002. It assumed the right to preemptively attack an enemy state if there was a perceived nuclear threat. Five NATO generals recently issued a manifesto that allows preventive strikes using nuclear weapons.

Underlying MAD and similar retaliation strategies is an assumed universal fear of death. Its corollary is the drive to live. Preventable, premature, horrendous death is to be avoided at all costs. MAD and other forms of deadly retaliation work as long as the enemy fears death of oneself, loved

ones, and the population at large; fears destruction of their state's culture and infrastructure; and has rational people in positions of responsibility. However, the assumption of universal fear of death is challenged by suicide bombers and other true believers. Killing the invader or hated, repugnant other is reinforced by patriotism, the opportunity for revenge, or theological promise of rapture and martyrdom.

A world free of nuclear weapons is the ideal goal of the antinuclear war, nonproliferation coalition. Diplomacy and other forms of soft power are seen as having more potential to attain peace than military or hard power. The process demands global cooperation to eliminate nuclear stockpiles, fissile materials (especially HEU and plutonium), technology, and the motivation to use weapons of mass destruction.

Part of a soft power and diplomatic approach is to integrate the behavioral sciences and the contributions from disciplines such as cultural anthropology, human development, education, psychology, sociology, thanatology, and theology. Policy makers and practitioners need to integrate empathy and understanding of the enemy's culture into action if nuclear aggression is to be avoided.

Conclusion

Preventing nuclear annihilation and other forms of HD is the overriding health, well-being, and survival task of our time. Eliminating the actuality and threat of HD will require a global effort.

Memorial Day

The origins of Memorial Day (or Decoration Day, reflecting its primary activity of decorating soldiers' graves) in the United States have long been disputed. Essentially a day set aside to commemorate the dead of the Civil War, the debate over its origins—a debate that has now moved online—involves a variety of dates and a broad geographical range of places from Boalsburg, Pennsylvania, to Columbus, Mississippi, and several cities in between laying claim to the "first" Decoration Day ceremonies. In 1966, President Lyndon Johnson officially designated Waterloo, New York, as the birthplace of Memorial Day, because Waterloo had celebrated the occasion in 1866 and had made it an annual event afterward. In 2001, historian David Blight pushed this date back further with a plausible argument that the first Decoration Day had, in fact, been organized by black South Carolinians and white abolitionists, and took place at Charleston's Race Course Cemetery in South Carolina on May 1, 1865.

Memorial Day's official incarnation, for the Union side at least, is generally dated to May 30, 1868, with a ceremony at Arlington (which later became the National Cemetery) and credited to the efforts of John Alexander Logan, founder of the Union veterans' organization, the Grand Army of the Republic (GAR). Logan had announced in General Orders No. 11 that May 30 of each year be "designated for the purpose of strewing with flowers, or otherwise decorating the graves of comrades who died in defense of their country during the late rebellion, and whose bodies now lie in almost every city, village, and hamlet churchyard in the land. In this observance," Logan proposed, "no form of ceremony is prescribed, but posts and comrades will in their own way arrange such fitting services and testimonials of respect as circumstances may permit." It was through the efforts of the GAR that Memorial Day became a national holiday. Because it was largely due to the GAR, Logan argued, that "an annual commemoration to the departed heroes of the war had been inaugurated," to the GAR, therefore, fell the "mournful and pleasing duty of perpetuating it." In the aftermath of an internecine war that had cost over 600,000 lives, the need for such a ceremony was strong and universal. Memorial Day became, as historian Michael Kammen notes, "an instant national tradition," and over 31 states had adopted the day as a holiday by 1869.

The pattern that Memorial Day followed can be compared to early Armistice Day ceremonies in Europe. It was primarily a funereal occasion, constructed around and following the precepts of antebellum mourning ritual. A parade to the cemetery frequently led by veterans was followed by the laying of wreaths or flags on each individual grave and later, when the ceremony became more elaborate and, arguably, more political, formal speeches by politicians became a central focus for the proceedings, which usually had a musical accompaniment. By 1891, for example, Memorial Day in New York, as described by *The New York Times,* was a day-long event, beginning at 8:00 in the morning with parades, speeches, and the traditional oration and musical entertainment held in the Metropolitan Opera House, concluding with organized detachments of veterans decorating the various memorials to the Civil War (and to the Mexican War of 1846–1848) around the city. However elaborate it became in the city environment, for much of the 19th and early 20th centuries,

Memorial Day remained focused on the local cemetery and on the graves of the dead, which were decorated with flowers. Civil War veterans were positioned at the center of the ceremony, but public officials, noncombatants, and ministers of religion offered prayers, eulogies, and speeches. Children were a significant element in Memorial Day, as they were in Armistice Day ceremonies. Sometimes their involvement was symbolic of Union sacrifice, as when the children of the Union Orphan Asylum in Baltimore were brought along to decorate their fathers' graves; at other times their involvement had a broader significance and symbolized the importance of Memorial Day as an occasion for reinforcing civic values and precepts among the generations growing up after war.

David W. Blight's study of the complexities of the reunion process in the Civil War's aftermath highlights the reinforcement and refinement of antebellum mourning ritual through Memorial Day. Memorial Day not only revivified the art of the funereal oration, but established a ceremonial occasion through which Northerners, at least, could not only "understand their sacrifice of kin and friends," but identify anew with the idea of America as the "New Israel" and its people as God's elect. Its efficacy in this regard was provided by the new element that the war brought to the concept of America's missionary role, that of redemptive sacrifice in the nation's name. The Memorial Day oration of Union veteran Robert Green Ingersoll in 1882 made this clear in its potted history of the nation, its emphasis on the sacrifices of the Revolutionary generation, and its stirring injunction that Memorial Day was an occasion on which "the story of the great struggle between colonists and kings should be told." The cult of the fallen soldier in America did more than legitimize the war experience; it validated America's national existence. In this sense, expressed most cogently through Memorial Day, the Union dead provided the nation with the most important component of their sacred trust narrative. Through their sacrifice America's existence and its position as the redeemer nation of the modern world was secured.

Alternative Traditions

The celebratory aspect of the North's version of Memorial Day clashed with the more overtly funereal overtones of white Southern ceremonies for the Confederate dead. These ceremonies took place in the context of memorializing not just the fallen, but also the defeat of the Confederacy, and were deliberately set apart from the May 30 event in the North. The rejection by the white South of national Memorial Day celebrations was not surprising. Whereas Northerners could take comfort from the fact that their dead had died in defense of the nation, and accord them full military and social honors, Southerners were left to bury their dead apart, as a putative nation within a nation. The defeat of the Confederacy left its supporters on the sidelines in the new civic nationalism that the North trumpeted so effectively at Gettysburg National Cemetery, Arlington National Cemetery, and elsewhere in the years after the war. Memorial Day ceremonies in the South, although central to the development of the Lost Cause, could only exist as shadows of their Northern counterparts; the unwelcome—but nevertheless persistent and increasingly influential—ghosts at the nationalist feast of post–Civil War American civic ritual.

In both the North and the South, the ceremony conveyed a strong political message from the start, but in the years immediately following the Civil War, the South was constrained in the degree to which it could, overtly, commemorate its dead and the cause for which they had died. Excluded, for obvious reasons, from the burial and associated commemorative ceremonies accorded the Union dead, the bodies of Confederate soldiers were often unmarked and unacknowledged, but not for long. Ladies' Memorial Associations in the white South took on the task not only of commemorating the dead, but of repatriating the bodies of Confederates. This act established, in a real sense, the sacred ground upon which not just Confederate Memorial Day, but the later Lost Cause tradition of the South would be celebrated. Beginning in Columbus, Georgia, in the spring of 1866, Southern ceremonies focused around the "Cities of the Dead," in which the departed were buried in what one editorial termed "their silent houses of clay," but through which the ambitions of the survivors were kept alive.

Unlike in the North, no specific day emerged as the occasion for Confederate Memorial Day, and individual communities selected days that best suited their needs. What they had in common was

a strict outward adherence to traditional, antebellum mourning ritual, which Union onlookers (the Southern states remained occupied by Union troops until 1877) could hardly find fault with. The dominance of women in such ceremonies both followed this pattern and deflected the suspicion—hardly unfounded—that Confederate Memorial Day was as much about keeping Confederate traditions alive as it was about commemorating the dead. In historian William Blair's pithy phrase, Confederate Memorial Day represented "a form of guerrilla warfare through mourning." As in Northern ceremonies, the veteran presence was crucial on Confederate Memorial Day, but in its earliest incarnation, the ceremony had more unsettling military overtones, in some respects, than its Northern counterpart, with the former Confederate soldiers in their old military units, and their prior military leaders (rather than ministers) frequently taking charge of proceedings. This obvious challenge to Union victory quickly diminished after 1867, and Southerners hid any persistent sectional sentiments under a funereal shroud, at least until the Reconstruction ended 10 years later and the last of the federal forces were removed from the South.

Developing a National Tradition

If the North and the South expressed different sentiments through Memorial Day, both nevertheless interpreted the occasion within what Garry Wills has termed the 19th century "culture of death" through which the "place of the dead" provided "a school for the living," and which "made mourning serve life." In Memorial Day's contemplation of the soldier as a sacrifice of war, even in its Confederate variant, the emphasis increasingly focused on the importance of war to the American nation, to its continued existence, and by the later 19th century, the nation's well-being came to reside in the reconciliation of former foes. Memorial Day's emphasis on the "heroic dead" permitted both the North and the South to take from the ceremony reinforcement of their respective positions during the war, and for the South, in particular, offered a route back into the nation via an emphasis on the cost of their sacrifice over its cause. This in itself was cause for concern to some who, in the words of an 1878 editorial, objected to the growing tendency "to obliterate the sharp distinction between battling to save the life of the Nation and fighting to destroy it."

Such concerns over the appropriateness of commemorating the Union and Confederate dead together were soon overtaken by a more general fear that the message of Memorial Day was becoming diluted, less a ceremony to honor the dead than a holiday for the living. It seemed inappropriate to the editor of the Bangor *Daily Whig and Courier* in 1889 that Memorial day in Maine should be the occasion for a baseball game; such a development lacked the necessary "sense of propriety" on a day "set apart for the solemn ceremonies of honouring the memories and visiting the graves of the dead heroes of the Nation." This was not a situation unique to Maine; throughout the nation, even in parts of the South, the decline of ritual observance of the dead on Memorial Day was noted. The ceremony was somewhat reinvigorated after World War I, when Memorial Day was expanded to honor the American dead of all wars. By then even the South was prepared to acknowledge it as a national event, although many Southern states retained a separate day of commemoration for the Confederate dead; in the case of Louisiana and Tennessee, selecting June 3, the birthday of Jefferson Davis, President of the Confederacy.

In the context of 20th-century conflicts, Memorial Day broadened its celebrations to include the wearing of poppies to honor the dead of war, as in Europe, and in 1971, became an official holiday under the National Holiday Act, celebrated on the last Monday in May. The focus on cemeteries and graves remains central, and the official ceremony places flags rather than flowers on the graves at Arlington National Cemetery and a wreath on the Tomb of the Unknown Soldier. Since 1998, candles have been placed on the graves at Fredericksburg and Spotsylvania National Military Park. Echoing the concerns of the later 19th century, however, the persistent sense that the memorializing aspect of Memorial Day has been lost is expressed not only by the veteran community in the United States but by the federal government, each of which has taken a variety of steps since 2000 to reinvest Memorial Day with what is perceived to be its "traditional" meaning as a day of remembrance for America's war dead. To this end, on May 22, 2008, President George W. Bush, acting on a Joint

Resolution of Congress, proclaimed Memorial Day "a day of prayer for permanent peace," to include both a "National Moment of Remembrance" to begin at 3:00 pm on that day and appropriate displays of the American flag (half-mast until noon) on public and private buildings, an overt expression of the continuing centrality of the war dead to America as a nation, and Memorial Day's significance as the sacred ceremony at the heart of the nation.

Memorials

Studies of memorials for the dead reflect a wide range of interpretations. The Taj Majal, the pyramids of Giza, the Vietnam Veterans Memorial, and the graveyards of Puritan New England, to name but a few, have been approached from architectural, archaeological, aesthetic, and genealogical perspectives. They have also been considered in relation to ideas about status, identity, ethnicity, and social history. However, with these diverse approaches there has often been the embedded assumption that grave markers signify individual interment sites that permanently record the identity of the deceased. In contrast, more recent studies have demonstrated that interment, place, and permanence are not universal, all-pervasive social practices. Rather than frozen in time, cemeteries and memorials have been shown to represent dynamic collections of artifacts subject to the same practical, interpretive, and historical processes as any other cultural text. Furthermore, interment in cemeteries, the marking of individual graves, and the permanent sanctity of grave locations represent just one form of mortuary practice. Thus, recent approaches to the nature of grave markers, cemeteries, and memorials provide us with a more complicated historical and sociocultural perspective by which to understand the relationship between the living and the dead as expressed through material culture.

In many Western countries, the rarity of grave markers prior to 1800 has been commonly attributed to factors of haphazard preservation. However, some studies now suggest that the use of permanent individual gravestones was an occasional practice that became a social norm only after 1800. Prior to that time, individuals whose families sought to maintain continuity and a kindred connection with their ancestors were those most likely to have erected permanent grave markers. Particularly in Europe, interment occurred in a variety of locations, including family courtyards, rural property, and the floors of homes and churches. Final disposition of remains also took place in common graves, such as charnel structures or open garrets. Specifically in Greece, evidence for the practice of secondary burial goes back to the time of Alexander the Great. While European

cemeteries did appear as early as the 12th century, and were often associated with churches or other ecclesiastical structures, it is now understood that a wide variety of local and ethnically based community burial traditions were also practiced.

Graves, Markers, and Cemeteries

The meanings and messages conveyed by grave markers cannot be fully understood without recognition of the communities, histories, and sociocultural contexts in which the deceased lived and died. Gravestone studies, then, highlight a central paradox—death as a fundamental human experience is juxtaposed with death as a contextualized, situated experience. Both the dead and their associated gravestones are inextricably linked to the social circumstances and historical times that create, give boundary to, reify, and express meanings, metaphors, and symbols. As a result, a stroll through a local cemetery is likely to be both a familiar and an alien experience. For late-20th- and early-21st- century Americans, memorial parks filled with bronze markers flush to the ground appear familiar. Likewise, cemetery landscapes constituting slab-shaped gray granite tombstones, sparsely decorated and identifying the deceased by name, are likely to evoke a sense of familiarity. Nevertheless, cemeteries may also contain imposing white marble tablets, elaborate epitaphs that recall vivid imagery, full life-sized statues honoring and lending prominence to the deceased who lies beneath, symbols, metaphoric references, and even styles of lettering that we may be unable to recognize. Because shifts in time and perspective alter our view of these grave forms, their verbal, visual, architectural, and material messages may not be readily evident. Graves and cemeteries are part of the constantly changing social panoply, and death is simultaneously a universal constant and a specifically contextualized experience.

The association of specific gravestone motifs with historical periods was first demonstrated on New England Puritan grave markers. The gradual shift from death's head to cherubs, willows, and other benign images suggests the earlier Puritan view of fearful death became replaced over time by more peaceful views of the afterlife. Further studies have revealed a dramatic increase in the use of individual grave markers throughout Europe and the British Isles from about the 1780s and into the 19th century. This remarkable florescence in the use of simple stones to mark graves seems to have ushered in a new period linking the living to the dead in that a stone became both a public gesture and a place to demonstrate the importance of the deceased to the bereaved.

In more recent periods, trends in the size, material, and configuration of grave markers can be interpreted within the context of expanding Western capitalism. Between 1850 and 1920, for example, grave markers demonstrated a clear reflection of status and social position. However, from about 1920 throughout the 20th century, American cemeteries have reflected a decrease in cemetery marker investment, much greater uniformity, a drastic decrease in large family plots, and the social inconspicuousness of flush bronze markers. For many, this decrease in the visibility of death on the literal and cultural landscape has simply been a reflection of attempts to deny the reality of death. From an ideological perspective, however, these changes indicate a shift from direct expressions of power and status to a masking of status, a denial of inequalities and power relations, and a misrepresentation of the true nature of social relations. Thus, rather than representing mere repositories of stagnant sociocultural norms, we are coming to understand the active role cemeteries have played in American discourses about life, death, and society.

Commemoration, Monuments, and the Historical Dead

A central function of gravestones and cemeteries is to serve as material embodiments of memory. But while memorials appear to be permanent, memories are constantly changing. Therefore, dynamic dialogues between the living, the dead, and grave markers juxtapose complex connections between bereavement, living memories, transforming values, and time. Furthermore, loss of direct remembrance caused by the deaths of successive generations further complicates processes of memorialization and the interpretation of relevant material forms. In addition, historical events, changing collective identities, and shifting interpretations of history can be reflected in our cemeteries and memorials. Cemeteries, then, link the dead to the living so long

as memory among the living is served. Once the surviving memory has likewise taken up residence among the dead, the immediate attachments to individual and community are lost.

Monuments are venues for collective remembrance. Prior to the mid-18th century, monuments were built to and for the elite as a material representation of preordained destiny. These monuments played a part in the constructed linear histories meant to assert the importance of specific times, events, people, and places. However, during the 18th century, the formation of nation-states began to require both the creation of popular common histories as well as the extinguishing of traditionally held boundaries, and the sense of identity began to shift from that of personal ancestry to a collective identity and shared, public heritage. Thus, the rise of national commemorations and the construction of national monuments were purposeful, ideologically driven strategies by which connections to the historic past were broken and new pasts were created.

American Civil War cemeteries further demonstrate the dynamic processes inherent in collective memorialization. The loss of 600,000 soldiers during the war resulted at times in the sorrowful sentiment, "Let the dead bury the dead," because soldiers and civilians alike were overwhelmed by the sheer number of corpses. There was a practical need to dispose of massive number of dead at the sites of battles, skirmishes, prisoner of war camps, and military field hospitals. At the same time, families demanded to know the site of interment for loved ones or to have bodies returned to them for burial. As early as 1861, the War Department issued regulations for recording the dead and burial of Union soldiers, including the marking of all military graves with "headboards." Instructions to secure space near battlefields for interring the dead, and the establishment of the first national military cemetery in July 1862, were also issued. At the same time, a florescence in the embalming of corpses fueled the funeral industry as the demand for the return of the war dead to the families steadily increased. Finally, the rebuilding of an American national identity through commemoration and monuments was galvanized with the assassination of Abraham Lincoln on April 14, 1865, and his interment in Springfield, Illinois, 20 days later.

Later in the 20th century, as the ranks of surviving Civil War veterans thinned, Civil War cemeteries began to transform from memorials of individual lives to places of broad historical significance. Rather than private graves, they became focal points of commemorations and public spaces where collective memories and shared events are given form and meaning. Providing an interesting contrast to the few marked graves of American Revolutionary War soldiers, massive cemeteries and even isolated graves of Union and Confederate soldiers dot the landscape of the Eastern United States. Each marked spot bears witness not so much to individual lives but to the role those lives played in a significant national conflict. These memorials no longer invoke direct memories among the living but bring to mind and materially sanction contemporary narratives about the Civil War. Thus, the events and sacred places created by the conflict of Civil War became ensconced in American discourse, enshrined in our material culture, and forever altered the American landscape.

World War I had a similar, transforming effect on Europe. France alone suffered over 1.3 million military deaths. One response to coping with such vast numbers was to create massive memorials that listed the names of those who had died in specific battles. The building of the Menin Gate to commemorate the battle of Ypres, for example, inscribes 54,896 names. The wall memorial of Tyne Cot contains the names of 34,888 and is surrounded by 11,908 individual graves. The colonnades of the Ploegstreet memorial list 11,447 names; the Duds Corner Memorial forms a walled courtyard with 20,589 names. The Thiepval Monument memorialized the dead from the Battle of the Somme, listing 73,367 names of soldiers whose exact resting place is unknown. Tens of thousands of other names are recounted on similar memorials. There also are the cemeteries, with an estimated 678,000 identical gravestones. In short, the task of memorializing became as massive as the loss of life itself.

A second response was the creation of the Tomb of the Unknown Soldier in the United States and the Tomb of the Unknown Solider in England. The devastating reality of World War I included the vast number of unidentifiable dead and those who could not be accounted for, well over 500,000. Both the Cenotaph—the empty tomb—and the

Tomb of the Unknown Warrior appeared in the 1920s as responses to these losses. Focusing on collective loss, the Tomb of the Unknown Warrior and its variant nationalistic forms created a symbolic space for the return of all war dead represented in the remains of a single individual. Bereavement and mourning became as classless as the remains of the interred solider. Individual loss was now encompassed by public grieving and remembrance. The empty tomb took this hypernominalization of loss one step further by symbolically representing the generic body. The collective loss became represented as the same for all.

Monuments and events commemorating World War II reflect a different sense of loss, resonating with the events of that time. The reconstruction of Germany and Japan, for example, emphasized a forgetting of militaristic activities. Citizens of both countries delayed openly commemorating their war dead well into the 1950s. On the other hand, the victorious nations found the celebration of heroism and sacrifice as important as commemoration, and emphasis shifted to surviving veterans and eventually those who had provided support from the home front. Parades, veteran's organizations, and living memorials predominated over the construction of monuments. Finally, all nations had to confront the horrors of the Holocaust and the massive loss of more civilians than soldiers during the war. Individual memory of those events began to find collective representation in the 1950s and continues to the present.

The Vietnam Veterans Memorial provides yet another distinct example of the commemoration of war, in this case a military conflict that evoked both strong national dissension and ambivalence. The minimalist choice of listing the names of the dead, the absence in the original design of symbols associated with traditional war memorials, and the use of black marble attempt to acknowledge loss of life. The monument's inclusion of names personalizes the sense of loss, and in so doing provides a public space for conflicting feelings and experiences associated with this war to coexist. The meanings of this monument are most importantly conveyed through its uses rather than through the juxtaposition of symbols. The form of operational meaning that began during the early construction phases of the monument, whereby people left gifts and tokens along the wall in memory of loved ones, persists as items continue to be deposited, photographed, collected, and stored. The monument, then, has offered a public venue to express private feelings. How it will serve collective memory once the generation of Vietnam veterans has passed remains to be seen.

Monuments and Politics

Monuments to individuals may also codify explicit, though veiled, political sentiments. Various periods of renewed nationalism in America have witnessed the negotiation and renegotiation of monuments expressing dominant cultural values along with selective forgetting. Groups such as the Mount Vernon Ladies Association, the Daughters of the American Revolution, the Daughters of the Confederacy, and the Emancipation Group, for example, each sought to shape collective memory of the past. Specifically, the Emancipation Group sought to commemorate the "Freedman" as the personification of the Reconstruction ideals of the Fourteenth and Fifteenth amendments. At the same time, although both Northern and Southern groups focused increasingly on the heroic deeds of local heroes, the wording on monuments emphasized the Union in the North and state sovereignty in the South.

The sole monument to emancipation was the Freedman's Memorial, designed by Thomas Ball, and funded entirely by the contribution of free blacks. After years of wrangling, and the failure of earlier designs, Balls' monument was erected in Washington, D.C., on April 14, 1879, the 11th anniversary of Lincoln's death. Intended to convey the self-determination by which slaves actively participated in breaking the shackles of slavery, the memorial instead portrays a slave kneeling at the feet of Lincoln having just realized his chains were broken. Frederick Douglass, who delivered the oration at the memorial's dedication, in fact objected to the slave's kneeling posture as unmanly, manliness representing, to Douglass, the opposite of slavery. Thus, the intent to express freedom in the Freedman's Memorial is ultimately subverted through the positions of its figures. The dominant representation of Lincoln further subverts the status of Freedmen.

Monuments remain powerful symbolic elements in our landscapes precisely because they are built

to endure, distilling a representation about the past long after the events, debates, and disputes that created the monuments have been forgotten. Perhaps precisely because monuments appear inert and permanent, these features are also subject to continual reinterpretation. The rapid tearing down of the Lenin and Marx statues through old Soviet Bloc countries in 1989 seemed to resonate with the removal of statues of Tsar Alexander III during the Bolshevik Revolution, which brought Lenin and Marx to prominence.

The public spaces shaped by monuments and the individual they commemorate both mirror and are shaped by societal values. They are forums that articulate collective memory and popular consensus. They are also cultural sites in which the memorialization of selective individuals galvanizes debate and thus reflects the ways in which the past is contested. The creation, design, construction, modification, and destruction of monuments are neither a permanent testament to the past nor a static process. Levinson notes, "To commemorate is to take a stand, to declare the reality of heroes or heroic events worthy of emulation, or less frequently, that an event that occurred at a particular place was indeed so terrible that it must be remembered forever after as a cautionary note." It is this process, rather than the inert structures themselves, that lend meaning both to monuments and to the events they commemorate.

Memorials, Quilts

Quilts have for centuries been one of the most consistent forms of textiles used in the home. Through the centuries, quilts have also served multiple purposes—as bedcovers, of course, but also as shrouds or coffin liners or covers; sleep has always been closely associated with death. Historically, the making of quilts was often a shared activity, providing women in a community with sociability and the opportunity for creative expression, a welcome—and productive—diversion from the more isolating and physically demanding tasks of housekeeping. A new availability of endlessly patterned and colorful commercial fabrics for use in dressmaking and upholstery helped to spur a lively flourishing of creative expression in 19th-century America well beyond utilitarian purposes. Quilts became a way to celebrate or commemorate significant events in one's personal life or in the community or nation. A particular type of commemorative quilt that can take many different forms is the memorial, or mourning quilt, which memorializes the deceased, whether an individual or a community of individuals.

Memorial quilts largely fall into two categories: those honoring an individual and those commemorating a community of individuals.

Mourning Quilts in America

With the elaboration of mourning practices and a new emphasis on memorialization in America in the 19th century, quilts became one of the most intensely personal ways to express grief, loss, and memory. Mourning customs, directed particularly toward women, dictated everything from the color of a widow's clothes and jewelry and the specific length of time she was expected to mourn, to the size of the black border around her stationery. As part of their education, young women created embroideries and samplers that memorialized a deceased family member or friend, following accepted conventions of needlework.

The most personal expressions of loss are usually found in memorial quilts for individuals. In the 19th century, with high rates of infant and child mortality and frequent widowhood, mothers and wives often found solace in creating quilts to honor their loved ones. Designs typically used the colors of mourning—black, white, and shades of gray, possibly with shades of purple as well—with black borders, similar to the stationery and handkerchiefs widows used. Some designs used symbols and motifs found on gravestones—for example, the lyre with a broken string or the funerary urn. These quilts could replace the more brightly colored bedcovers in the bedroom, at least for a while.

Another personal expression of mourning was the "memory quilt," in which a quilt was pieced together from the deceased's clothing. Based on documentary sources, it appears this particular type of quilt was often made by women mourning other women—pieces of the deceased's dresses, which themselves had typically been made from brightly colored calicoes and cottons, were joined together, with religious sayings or sentimental verse memorializing the deceased embroidered in the middle white square. Occasionally these quilts also acted as albums for friends and family, who included poems, sayings, and signatures, attesting to their grief and love for the departed. Memorial ribbon quilts incorporated pieces of ribbons from the deceased's funeral services. The making of the quilt provided a therapeutic and comforting way to work through grief, while the finished quilt acted as a "memory" of, and connection to, the deceased. The tradition of incorporating pieces connected to the deceased's life or pictorial symbols relating to mourning and loss seems to have been practiced in most communities, regardless of ethnicity, race, or socioeconomic class during the 19th century.

Quilts as Memorials

The other major type of memorial quilt is one that commemorates an event that has caused the death of large numbers of people or that has caused mourning on a communal, or even national, scale. The Civil War, a watershed event in American history that disrupted the very fabric of American society and life in its enormous loss of life and devastation, was the direct cause of the creation of thousands of quilts memorializing individuals or even regiments. In 1986, the *Challenger* space shuttle disaster spurred many quilters to create their own expressions of shock and grief. More recently, the events of September 11, 2001, have provided the impetus for numerous individuals and groups across the country to create memorial quilts commemorating that day and its aftermath, as the event in recent history caused mourning on a previously unimaginable nationwide scale. The Mothers Against Drunk Driving (MADD) quilts are just one example of a memorial project inspired by personal loss that helps to raise public consciousness about avoidable tragedy. Similarly, the Iraq War has been the inspiration for numerous memorial quilts, inspired by individual deaths or by larger concerns about the devastation and tragedy of warfare.

Probably the most publicly visible and famous quilt today is the NAMES Project Quilt, better known as the AIDS Memorial Quilt, which commemorates the victims of the AIDS epidemic. Begun in 1987, the quilt is constructed of cloth panels, individual "quilts" of 3 by 6 feet, which are joined in blocks or sections of six panels. The panels are made by friends and families of the deceased, and are highly personal expressions, ranging from simple to elaborately decorated, often containing mementos and souvenirs of the deceased. The AIDS Memorial Quilt grew quickly in size and the panels now number more than 40,000. Because of its enormous size, only sections of the AIDS Quilt

can be exhibited at any given time, often in cavernous settings (for example, a warehouse or a football field), leading to controversy over whether it really can be called a quilt, or an artifact (never in one piece) that has lost all reasonable association with the more personal, intimate proportions of a human body. Regardless of this disagreement, the AIDS Quilt has clearly provided a mode of expression for memorialization on a national and even international scale, and a way to remember thousands of victims of AIDS and AIDS-related diseases. Panels continue to be added to the AIDS Quilt, the largest ongoing community arts project in the world.

Memorial Quilts in Other Cultures

Other countries and civilizations have practiced indigenous forms of quilt making as part of mourning and burial rituals. The people of Native American tribes, Europe, Tahiti and Polynesia, Central and Southeastern Asia, the Middle East, and Russia all have documented traditions of making memorial or burial quilts to commemorate the deceased. Often these are made in traditional patterns associated with mourning, using specific colors, types of cloth, and motifs.

Memorial Quilts Today

Even as the preparation and care of the deceased's remains was increasingly taken over by commercial funeral parlors and hospitals in the late 19th century and the care of the dead became a matter for professionals, the making of quilts retained their important function as connections to the deceased. Today, whether as makers or observers, memorial quilts still bring people together at times of loss and tragedy to honor the departed and to mourn as part of a community or a nation.

Memorials, Roadside

Roadside memorials may be created by individuals or groups spontaneously or as a planned activity. Memorials often function as a way to communicate with the deceased as well as a means through which mourners express their grief while also memorializing the deceased. In the United States, such practices have been documented in newspaper accounts and diaries from the 19th century, as well as literary sources and newspapers in the 20th century. This practice has been reported in a number of countries around the world, including Mexico, Canada, Greece, and Australia.

Roadside memorials mark the site where a fatality has occurred. Although usually the result of an automobile collision, the fatality may have resulted from other causes (such as murder or from natural causes while traveling or exercising).

Memorials are utilized by mourners as a way of coping with deaths that are sudden and tragic in nature. The most common components of the memorial are a cross and artificial flowers, although numerous other artifacts may be utilized as well. Some of the functions served by these memorials are to prolong the memory of the deceased in a public place, to communicate with the deceased, and to transmit a message to society, serving as both an expression of mourning and an attempt to warn others of the dangers associated with driving.

History

The placing of markers at the site of a death is reported to date back hundreds of years to Europe in general and to Spain in particular. Controversies related to roadside memorials typically revolve around the rights of mourners to place a private marker on public lands or on public right-of-ways.

In this era, the deceased are not buried at the site, but the marking is a notice that something

significant happened on that site. Roadside memorials almost always hold some religious significance, although that significance is more likely to be general in nature rather than a religious ritual prescribed by one's faith. An early practice in England involved cutting in the stone or scratching in the dust the sign of the cross at the site of an accident or a murder. This practice was not only to pacify the ghost of the deceased, but to keep the ghost from haunting the location, and to allow passersby to continue to remark the spot. For example, in Mexican Catholic tradition, the memorial marks a spot where someone died without receiving Last Rights, and thus serves as a reminder to passersby to stop and pray for the deceased.

The use of crucitas (or little crosses) has been traced back to Spain and the conquest of the New World. In Spanish tradition, crosses by the side of the road marked the resting place for those who were carrying a coffin to be buried. The tradition of placing roadside crosses to mark the spot where an untimely death occurred has survived in South Texas and followed Mexican-American migration to other parts of the country. Not limited to Mexican or Catholic tradition, death memorials have also been used by the Tohono O'odham tribe of southern Arizona to mark the locations of violent or "bad" deaths for several decades. Indeed, roadside memorials are placed by a wide variety of people representing various religious and cultural backgrounds.

Functions

Roadside memorials serve a number of functions both for the bereaved and for the community. Placing a roadside memorial may serve as a mourning ritual in which the bereaved attempt to find meaning in their loss by warning others of the dangers associated with driving. Such memorials may be placed spontaneously while visiting the site, or the result of meticulous planning, to be placed at some later time.

Although some of these memorials are constructed by a group of family or friends, they may well be the act of an individual as they mourn their loss. Though a private act of mourning, the roadside memorial is in a public place; however, the community-sanctioned site for a memorial is in the cemetery. Roadside memorials may also be placed or contributed to by people who may not have participated in the planning of traditional mourning ceremonies, including friends, colleagues, community members, or relatives.

The artifacts left at roadside memorials are similar to those left at other spontaneous or impromptu memorial sites, including both traditional and idiosyncratic mementos. Examples of traditional mementos include a cross, flowers, praying hands, candles, and stuffed animals, or artifacts more idiosyncratic in nature such as cigarettes, beer cans, shoes, articles of clothing, or personalized written messages. Artifacts, such as a cigarette, may represent an activity previously shared by the deceased and the bereaved; however, in many cases, the meaning of the mementos is known only to the person placing the item.

Benefits for Mourners

Roadside memorials are not limited by traditional schedules of mourning or ritualization. As soon as a fatality is made public, artifacts in honor of and in memory of the deceased are placed at the site of the tragedy. Whereas family members will be invited to the hospital or funeral home for preparations and decision making, people not included in this process can conduct their own memorial rituals by visiting the site of the fatality, attempting to understand how the tragedy occurred, and leaving personal mementos at the site. Roadside memorials are often put into place before the public ceremonies are held, serving as a gathering place prior to the day of the funeral as well as afterward.

A roadside memorial site is a noninstitutional site, in contrast to the cemetery with rules and regulations regarding memorializing behavior and staff to regularly remove unacceptable artifacts. By contrast, the roadside memorial site may not be restricted by such rules or have oversight by staff who can insure compliance.

The bereaved may visit the site at any time; however, certain times of the year are common for visiting these sites, such as the holidays of Christmas, Easter, Halloween, Thanksgiving, Valentine's Day, and Memorial Day. Other special days for visiting the site include the birthday of the deceased and the date of the death.

Another important contrast to the cemetery is that a roadside memorial site does not house

physical remains. Perhaps there is also more of a mystical or spiritual element to the site where the tragedy occurred, because survivors are not faced with the awareness that the physical body is there in the ground. They can focus more on the fact that the person's spirit departed here and, according to some religious and cultural traditions, may in some ways still be present in that place. Another possibility is that in the face of feelings of helplessness, the memorials allow the bereaved to "do" something for the deceased.

Another function of roadside memorials is that they may include a political-social message about the cause of death and/or the implications of the death. These artifacts show the communicative function of the sites as a warning to others about the dangers of this location or of activities such as drinking and driving. This function leads logically to a discussion of controversies surrounding memorials placed by the side of the road.

Controversies

The major controversy surrounding roadside memorials revolves around the legality of placing them on property not owned by the person placing the memorial. More often than not, the memorial is on land owned by the state and thus certain limitations regulate how the land can be used. Maintenance of this roadside space is one logistical issue related to memorials, such that more time and attention is required to keep vegetation under control and thus maintain this space in a safe manner. Memorials overgrown by vegetation may be obscured from view, increasing the likelihood of being struck by a maintenance vehicle. In addition, the size of some memorials makes them a potential hazard if struck by another vehicle. Some memorials become quite large, but whether large or small, if not maintained the memorial becomes an eyesore. Other maintenance issues are that some of the materials left at memorials will decompose, such as a pumpkin or jack-o'-lantern and artifacts made of cloth or paper. Due to the effects of the weather, some materials need to be repainted to serve their memorializing function well. Some mourners use spray paint to write in large print across the road in graffiti-like fashion, which may be banned outright or become unsightly. Attempts to regulate memorials have included outright bans of such memorials, allowance with certain limitations on size and construction materials, and the placement of a state-sanctioned memorial upon request by the family of the deceased.

Some observers will criticize roadside memorials because they are tired of being reminded of the fatality every time they pass a certain place and that they think people should move on with their lives. The opinion of the majority of people appears to be in support of the right of mourners to place roadside memorials.

Logistical advice about roadside memorials includes avoiding the use of laminated wood, pressed wood, or particleboard, as these materials succumb to the effects of the weather quite rapidly. Metal or concrete markers may be a hazard to vehicles and passengers. Whereas fatalities have occurred to people visiting roadside memorial sites, other hazards include poisonous flora and fauna. The safety of mourners should be of paramount importance.

Memorials, War

War memorials have developed throughout time and have varying purposes within different historical eras and societies. Initially the purpose of war memorials was not memorialization at all but to commemorate a victorious leader. This tradition began in ancient times and continued through the early modern era. During the modern era, war memorials began to be constructed to pay homage to particular wars or battles. Contemporary war memorials have become part of the historical discourse of the wars they address and reflect national identity, define collective memory, facilitate traumatic healing, or are locations for ritual ceremonies.

War memorials are generally monuments, which are freestanding objects that serve the singular dedicatory purpose of memorializing war in a designated space that becomes sacred. They can, however, be buildings, locations such as battlefields, museums, or collections of memorabilia, or resources dedicated to sustaining the memory of a particular war or groups or individuals who fought in a war. In some cases, war memorials are placed on the site of a significant or decisive battle or at locations where many soldiers fell. In other cases, memorials are situated on public land within municipalities that wish to recognize the sacrifices of its residents, or in a nation's capitol as homage to incidents of national involvement that occurred elsewhere. War memorials that list or highlight individual deaths caused by war are generally a 20th-century phenomenon due to the perpetuation of some of the most wide-scale wars in human history.

Historic Foundations of War Memorialization

In ancient civilizations, the most attention was paid to the leaders of wars, and soldiers' deaths were marked in a similar manner to the death of any individual at the time. In ancient Greece, particularly during the Geometric period, large ceramic vases were used as grave markers, but those of soldiers were inscribed with distinguishing figures that storied the warrior's funeral. The Dipylon Vase (800–700 B.C.E.), for instance, a vessel over three feet high, depicts registers of schematized horses, soldiers, weapons, and shields with the dead warrior in the center rendered as a rudimentary solid figure laid horizontally amid the procession. A woman raises her arms in an iconic representation of mourning. Like most gravesites and markers in ancient Greece, objects such as the Dipylon Vase were devoted to single individuals, and the sites were used as gathering places for commemorations and feasts to which family and friends returned periodically.

Roman society also commemorated individuals at gravesites or in catacombs, rather than groups of individuals or wars. Victories in the Roman Republic were marked by the emperors themselves, usually through monuments glorifying their real or imagined prowess in leading armies in conquests. The exploits of each ruler are typically recorded on large triumphal arches such as the Arch of Titus (81 C.E.) and the Arch of Constantine (312–315 C.E.). Arches were generally singular like the Arch of Titus, or could be triple, like Constantine's, but all were of colossal size (approximately 40 feet wide and 70 feet high, respectively) and meant to emphasize the victories of the rulers rather than the might of the individuals who comprised the armies that served him. Another form of commemoration was a column, such as the 125-foot-high Column of Trajan (106–113 C.E.), in which the Roman leader had his exploits carved in a spiral around a 13-foot-wide column. Such practices are followed throughout European civilization thereafter, in which leaders are often monumentalized on horseback and without note of the many soldiers who served him.

Memorialization of War in the Modern Era

Shifts in war memorialization began to occur with monuments such as the 165-foot-high, 148-foot-wide, 72-foot-deep Arc de Triomphe in Paris, commissioned by Napoleon in 1806 and completed in 1836. This memorial was designed by Jean Chalgrin with iconographic reliefs of nude French youths fighting Germanic warriors and based on the Arch

of Titus. Another example is Nelson's Column (1840–1843) in London's Trafalgar Square, a 151-foot granite column designed by William Railton in 1838 and topped by an 18-foot sandstone statue of Admiral Horatio Nelson by E. H. Baily. Neither memorial lists the names of individual soldiers, and the forms follow Roman aesthetic precedent. As a precursor to the memorialization of individuals and the tradition of memorials that emerges in the 20th century, the American Civil War (1861–1865) became an important moment in history because the losses were so personal (often with different members of families fighting each other depending on their allegiance to the North or South), widespread, and devastating to the fabric of the fractured American society that many small memorials and large commemorations of battlefields resulted.

However, the modern concept of memorialization began to take note of and acknowledge individual losses from war. This coincides with technological advances in 20th-century war waging in which guns, mines, and bombs could inflict much greater damage on a larger number of individuals at once than swords, spears, or even muskets had in the past. In addition, a soldier was less likely to see his enemy or have as much warning of attack. In essence, as war became less personal and more catastrophic, attempts to commemorate it and the individuals who died while waging it became more important and widespread.

During the First World War (1914–1918), also know as the Great War or the War to End All Wars, which took place primarily in Europe, memorials were constructed in many locations, often small groups or villages taking it upon themselves to commemorate the loss of their fathers, brothers, husbands, and sons or with soldiers creating ad-hoc memorials on the site of a comrade's death in enemy territory. This was partially an antidote to the mass graves that had to be administered on battlefields and away from the soldier's homes because many soldiers could not be identified or have their remains returned home in sufficient time for proper burial. An example of a combined type of memorial is the Thiepval Memorial, dedicated on July 31, 1932, and the largest British war memorial in the world, containing the names of 73,357 officers of Great Britain and South Africa who died in battle at the Somme in France between July 1916 and March 1918. The form of the memorial is a 150-foot-high archway with legs that sit atop two other archways (123 by 140 feet) and surrounded by a cemetery of white crosses.

After World War II, many memorials continued to be built on battlefields throughout Europe. In addition, local towns continued to commemorate their war dead. Local governments erected "honor rolls" or lists of names in front of city halls or in central town squares. Although much of World War II took place in Europe, it marked the prominence of air power, the introduction of the atom bomb, and the use of large weapons and machinery. Much of American society was invested in the war in a way unlike past conflicts because of the Japanese attack on Pearl Harbor, the rationing of goods and supplies, and the inhumanity of the Holocaust. However, monuments rather than memorials prevailed in the aftermath of the war, the intent being primarily to glorify American victory. The United States Marine Corps War Memorial (1954), for instance, depicts the battle of Iwo Jima in Japan, one of the most decisive during World War II. And although the memorial is dedicated to all the marines who have given their lives in battle, it exemplifies the successful completion of a mission rather than the sacrifice of life that went into achieving it. Based on a Pulitzer Prize winning photograph of five marines and a navy corpsmen raising a flag atop the island mountain, sculptor Felix DeWeldon's 32-foot bronze figures raising a 60-foot flagpole was placed atop Horace Peasley's 10-foot base containing inscriptions of all of the marine corps engagements since 1775, when it was founded.

Contemporary War Memorials and the Significance of Design

The most marked shift in memorialization and the most significant war memorial to be constructed, however, is arguably the national Vietnam Veterans Memorial in Washington, D.C. Although national memorials were generally constructed with public funds by governments through official processes, the Vietnam Veterans Memorial was funded by private donations obtained by a group organized in 1979, the Vietnam Veterans Memorial Fund, which consisted mainly of Vietnam veterans and their families. The design of the memorial was

selected through a national competition whose parameters insisted that the final design be apolitical in nature, contain all of the names of the dead and missing (currently 58,249), be reflective and contemplative in nature, and harmonize with its surroundings. Congress approved its situation on the National Mall between the Lincoln and Washington memorials. Twenty-one-year-old Maya Lin's design was selected from over 1,400 anonymous entries, but its minimalist form, consisting of two black granite walls to meet at a vertex, was controversial, and a figural sculpture group of three men as well as a flagpole were added near its entrance.

Each of the memorial's two granite wings is 246 feet, 9 inches long, and they meet at an angle of 125 degrees, 12 minutes, and are edged against a grassy embankment. At its shallowest, the east and west tips, the memorial rises no more than 8 inches, with a height of 10 feet, 3 inches at the center. Each wall consists of 70 numbered panels inscribed with names that are listed chronologically in order of death date, beginning and ending at the vertex. Each panel is 3 inches thick and 40 inches wide and contains from 1 to 137 lines with 5 to 6 names per line. The names are .53 inch high and .015 inch deep and are listed in a phone book style directory located at the ends of the memorial. Each entry gives the full name, date of death, branch of service, and hometown of each individual, along with the panel number and row where he or she is located on the memorial. Next to each name a diamond marks the confirmed dead, and a cross designates each of the 1,300 missing. If missing in action (MIA) remains are returned, the cross is changed to diamond.

The nonconfrontational and nonnationalistic aesthetic of "the Wall," as it became known, immediately resonated with visitors and veterans upon its dedication on November 13, 1982, and it became a backdrop and destination for ceremonies, parades, commemorations, and healing, particularly during Memorial Day and Veterans Day. In particular, the memorial served as a magnet for veterans suffering from post-traumatic stress disorder because it finally, after the huge controversy surrounding the Vietnam War, which included protests, flights from the draft, and general unrest, brought the subject of America's lost war out into the open. It also served to commemorate the men who fought and died in the war, who had arguably not been adequately recognized by the public or government for their service.

Ironically, considering its humble and grassroots beginnings, the Vietnam Veterans Memorial has become the most visited commemorative site in the nation. At the Wall, individuals trace the carved names with their fingers, take rubbings of the names to get an imprint of the incised letters, use the location as a place for meeting former comrades, family mourning, or connecting surviving soldiers with the families of the dead. Objects such as photographs, medals, old army boots, teddy bears, poems, and even a vintage Harley Davidson have been left there, and the memorial has inspired literature such as *In Country* by Bobbi Ann Mason and a Hollywood movie by the same name, as well as events such as Rolling Thunder, a Memorial Day motorcycle ride for the purpose of drawing attention to MIA/POW causes.

The Vietnam Veterans Memorial has become the prototype for memorialization, not only for war memorials, but memorials to tragedies such as the Oklahoma Federal Building bombing, the memorial to September 11, 2001, the Columbine High School shootings, cancer memorials, and memorials to individuals. It also sparked a battle over the National Mall as a site for recognition of other wars through public memorials. Those who had fought in the Korean War also felt neglected and deserving of a memorial. This prompted World War II veterans, who, despite having been greeted upon their return by victory parades unlike the largely ignored veterans of the Korean or Vietnam Wars, to feel that they too deserved a memorial on the National Mall.

The Korean Veterans Memorial design was selected by competition from a concept initiated by a group of architects from State College, Pennsylvania, but was significantly revised by the firm Cooper-Lechy Associates for its execution. The purpose of the memorial is to commemorate the 1950–1953 conflict between North and South Korea (which is most well known from the television series *M*A*S*H*). It includes a field of bronze figures (by Frank Gaylord) making their way next to a wall etched with the faces of soldiers (by Louis Nelson), and also incorporates a pool of water, flag, and inscription honoring the veterans. The style of the national World War II Memorial is

imperialist in nature, taking over the middle center of the National Mall. It has symbolic stars, pylons with the names of regions where the war was fought, and the states that had contributed men to serve. Construction began in 2002, and it was dedicated on May 29, 2004. It was executed by a large team of architects, landscape architects, and carvers, and was based on a design submitted by Friedrich St. Florian. Relief sculptures line either side of the wide entry walkway and the large shallow fountain in its center acts as a recreational place for individuals rather than a solemn location of commemoration, mourning, and remembrance, as had become the tradition in war memorials. Rather, this returns to earlier imperialist gestures of Rome and Europe.

Mesoamerican Pre-Columbian Beliefs and Traditions

Strictly speaking, pre-Columbian cultures refer to American Indigenous groups who thrived on the American continents until the arrival of the Conquistadors (1492) and the posterior European influence. However, the term has a broader application due to the persistence of some native traits after the European conquest and colonization and the incorporation of the native population into the practice of Catholic doctrine and European culture. Even today, examples of this case of acculturation remain alive in some areas of Central and South America.

The main contributions of pre-Columbian beliefs and traditions to the study of dying, death, and human experience include the meaningful relationship that the living maintain with their dead ancestors and deities, as well as the methods employed to sustain such relationships. Many aspects of everyday life were affected by the cult of death, for instance, frequent placement of votive offerings, organization of war to collect captives for sacrificial purposes, promotion of superstitious beliefs, and more importantly, organization of fiestas and rituals that surrounded all celebrations of death. It was believed that an anticipated death was necessary for appeasing gods and benefiting the life cycle of the community, hence the imprint of sacrificial practices.

This entry focuses on relationships among the living and the dead ancestors, treatments of the body, beliefs in the afterlife, and notions of death and decay of pre-Columbian societies. Various sources of information allow an interdisciplinary approach, based mostly on archaeological evidence and ethnohistorical narratives (16th and 17th century chronicles written by Spaniards). It is possible to know the material culture used and the activities related to the rituals and ceremonies that surrounded death.

Mesoamerican Pre-Columbian Societies

Conceptions of death in Mesoamerican societies are mostly known because of practices of sacrifice and were mainly promoted by gruesome descriptions of 16th-century ethnohistorical accounts, which describe large piles of human hearts offered to deities in order to calm their thirst for blood. Furthermore, archaeological remains complement this view, due to the proliferation of temples (where sacrifices took place) and iconography representing morbid features, such as skulls, skeletal figures, human organs, deities of death, and captives of war. Spaniards considered ceremonies of sacrifice shocking spectacles, which led Mesoamericans to gain a reputation as violent and bloody societies, a fact that eclipsed interest in explaining the reasons why sacrifice was organized in the first place.

The twofold notion of reciprocity and cyclical time characterize Mesoamerican thought. On one hand, Mesoamerican societies shared the belief that their gods sacrificed themselves to create humankind. Hence, humans are permanently indebted to their creators, and failure to repay such debt would result in the devastating fury of their gods and in the end of human life and goodness. Priests constantly placed offerings of food in temples and performed rites of bloodletting (i.e., perforation of several parts of their body to induce intentional bleeding in the tongue, face, and/or penis). On the other hand, the notion of cyclical time is embedded in the idea of limited goodness. Thus, life has to be periodically renewed by the gods' blessing. These two pillars of Mesoamerican thought contributed to the development of profoundly religious societies to whom the cult of their deities was a warranty of their own survival. Paradoxically, the machinery of death was nothing but a mechanism to regenerate life and promote goodness and fertility within the society.

Aztec human sacrifices were performed on occasions of religious and political significance and were executed by priests of the highest rank. Most of sacrificial victims were war captives, to such an extent that the main objective of war was not the destruction of the enemy on the battlefield but the acquisition of the captives; thus, war was called "flower war" or "flowery war." Codices graphically illustrate details of the capture of victims and later sacrifice. Sacrificial victims were considered offerings and were used to reciprocate debts previously obtained. In addition, multiple sacrifices were also performed before the erection of buildings as is illustrated by the many sacrificed individuals found in the foundations of the Feather Serpent Temple of the city of Teotihuacan, possibly with the purpose of securing a sacred basis on which the temple rested.

The idea of an anticipated death was in some instances a good omen. For example, warriors who died on the battlefield and women who died in child labor were believed to enter the netherworld straightaway, and were even considered good deaths. Mesoamericans were used to coexisting with death, and it is not surprising that death was incorporated into many areas of their lives. For example, the cult of ancestor worship is a living tradition in many regions of current Central America. Ceremonies organized in honor to the god of death or god of the underworld, Mictlantecuhtli, were celebrated in the 9th month (Miccailhuitontil) of the Mesoamerican calendar, which coincided with the end of July and the beginning of August of the Gregorian calendar. Even if Indigenous communities adopted the Catholic doctrine, they continued to practice some traditional rites, among which the cult to the god of death was the most popular. This celebration was so popular that it was eventually incorporated into the Catholic calendar during the days of all souls and all saints (November 1–2), so that the celebration of the day of the dead, better known as *Día de los muertos*, had a pre-Columbian origin and is a living testimony to ancient celebrations. In fact, it is a good example of acculturation of the pre-Hispanic and European traditions. Rather than being a lugubrious celebration, the day of the dead is an occasion to gather with relatives and friends and is tinted by a festive atmosphere that stands out for celebrating life and communion among the living and the dead ancestors.

South American Pre-Columbian Societies

The study of mortuary evidence focused for a long time merely on chronologies, grave contents, treatment of the body, type of sites of burial, and especially on socioeconomic status, so that lesser attention was paid to question how mortuary practices functioned in each culture and to the study of social aspects of death. Nowadays, two main areas of interest are studied to explain the context in which pre-Columbian mortuary evidence of the South American region are found: the importance of the preservation of the corpse and the disposal of the burial.

South American regions have ideal environmental conditions for preservation, due to the dry coastal deserts and frozen mountains. Consequently, it is not surprising to find many mummies in good conditions. Ancient inhabitants of the region must have realized that situation too, hence the interest in using such conditions in favor of preserving the corporal existence of their dead by practicing mummification. The Chinchorro culture (ca. 6000 to 500 B.C.E.) provides examples that constitute some of the earliest evidence of mummification in the world. Adults and

children wore clay masks, and in some occasions the limbs were molded in clay too. These clay-molded mummies reflect a deliberate intention to turn the bodies as rigid as possible, perhaps with the purpose of transporting them.

Greater efforts were made to study the various techniques and procedures of mummification, such as natural and artificial mummification, methods of evisceration, removal of organs and stuff used for filling the corpse. However, little is known about the role played by mummies in their societies, apart from the documentation found in the ethnohistorical narratives. Spaniards regarded mummies as pagan idols and/or diabolic manifestations that incarnated the old beliefs and traditions, so that mummies were taken to represent obstacles to the process of evangelization and adoption of the Catholic doctrine. For instance, Muiscas (pre-Columbian society of Colombia) secretly continued mummifying some of their individuals long after the Colonial period; and by clinging to this practice, they resisted the imposition of an alien culture. Mummies were placed in caves that became sanctuaries of adoration, to whom Indians paid visits and presented offerings.

The practice of mummification has received a series of interpretations. In fact, a great emphasis was put on the relationship between mortuary remains and socioeconomic status, to such an extent that this view limited the study of further aspects, beginning with the reasons why mummification was preferred over other types of treatment of the corpse. An example of that is the Inca practice of curing the bodies of their rulers, which was merely interpreted in terms of assessing political hierarchy, and did not address topics associated with the mortuary disposal of rulers, such as insights into death, decay, the significance of preserving the corporal existence and postponing the social death of the leaders.

Individuals were mummified for sacrificial purposes too, as the Inca ceremony of *Capacocha* illustrated. This ceremony was performed in times of crisis, such as earthquakes, epidemics, droughts, or after the death of an Inca Emperor; and it involved the sacrifice of a child, which bestowed him and his family with high status. The child sacrificed was often the chief's progeny. On the day of the sacrifice, children were fed with *chicha* or an alcoholic beverage to ease the pain of the cold and altitude, as well as to be able to cope with the fear of their own deaths. However, skull fractures found in the sacrificed children indicate that children possibly suffered a violent death and they did not die due to exposure to the elements.

The practice of sacrifice is also represented in the iconography of statues and pottery. Mochica pottery is widely known because of the drawings printed on their vessels. For many years, it was thought that the scenes of dismembered and decapitated bodies were representations of myths and/or descriptions of battles between deities. Recent evidence from archaeological research in Huaca de la Luna has proved this assumption to be wrong and, on the contrary, it has revealed that people died due to violent causes. Skeletal remains present fractures of the backbone, skulls, and other bones, and it is likely the representation of large group sacrifices of captives; that is, individuals had their hands tied behind their backs. These discoveries show that iconography can be interpreted as historical testimonies rather than merely esthetical recounts of imaginary events.

In spite of the interest that Mesoamerican and South American pre-Columbian societies engender, the biggest challenge is to overcome the culture-bound limitations attached to current interpretations of the archaeological remains and ethnohistorical readings. This issue highlights the importance of learning about native ideas of death and life, profane and sacred spaces and behaviors. Questions about how death can be related to a wide range of different concepts, such as vitality, renewal, fertility, childbirth, and the completion of space-time cycles remain unanswered.

Current research involves the use of interdisciplinary approaches to the study of the region. One illustration of this is the study of iconography as a historical source of information, rather than as merely aesthetic. Detailed iconography and elaborate grave goods are excellent examples that summarized the cooperative arrangements that the living organized to introduce their dead into the netherworld and into the afterlife, by recreating a natural world in the hereafter. Curiously, there seems to be a tendency to find that the items related to death are more elaborated than the artifacts used in everyday life and/or domestic activities, which suggest the ambiance of pre-Columbian

cultures and invites us to explore the myths behind the motifs.

Middle Age and Death

To understand the relationship between middle age and death, these concepts must be situated in their cultural and historical context. In the case of people in the United States who are currently middle age, their historical beginnings are located between the late 1940s and the early 1960s, in that demographic cohort whose ideas, assumptions, values, and styles defined the era that became known as the baby boomers. At each stage of their lives, the baby boomers redefined the character of that age-specific category, from childhood through youth, until their current position, middle age, poised on the verge of what was previously referred to as old age, but now cast in a more flattering light as seniors or golden-agers.

The social scientific literature on middle age and death is fragmented, made up of the literature on the definition of middle age and the literature on the specific character of their death experiences, such as the care of elderly parents in decline, a task that makes it difficult for baby boomers to sustain the fanciful belief that came out of the 1960s that they would never age and never die. The purpose of this entry is to explain the attitudes of middle-aged people in the United States toward death, the particular character of their perceptions of death, and to point out the ways in which these attitudes and confrontations are grounded in their generation experience.

History of the Baby Boom Generation

That bulge in the population pyramid that represents the baby boomers, those who were born between 1946 and 1964, during a period of prosperity, were the major factors in explaining why the United States became youth centered. Their numbers and their spending power constituted a powerful force in the economic marketplace. They were listened to and courted as no previous generation of young people in the United States had been before. Their popular culture styles were imitated by both the younger and the older generations. They were led to believe that they were wiser and morally purer than their parents and grandparents, who, in a rapidly changing society, had nothing to teach them. One of their slogans, "Don't trust anyone over twenty-five," became "Don't trust anyone over thirty," and then disappeared. The new age category that Bennett Berger termed "almost endless adolescence" evolved in a youth-centered society into a middle age with an ever-expanding outer limit.

The cultural center of gravity during the 1960s became young people, with children at one end and middle-aged adults and the elderly at the other, tending to emulate youthful styles. As the baby boomers aged, they carried the importance of their style along with them. So, for example, jeans came to be worn by all age groups, and casual dress for one day a week even spread into corporate settings.

The baby boomers are beginning to reach retirement and are on the verge of old age. This is occurring during a period during which the United States has shifted to a less obvious death-denying society but one that is nonetheless obsessed with aging and its inevitable outcome, death. The images of old age are changing from white-haired men and women sitting in rockers smoking pipes or knitting to physically fit and smiling late-middle-agers on water skis or tennis courts. Euphemisms such as "seniors" are invented, and cosmetic surgery is used to mask the advancing years. The solution baby boomers have found for the depredations of old age is to never grow old.

Middle Age

The definition of middle age varies. The U.S. Census Bureau defines middle age as 35 to 65. A study of workers in a Middle Eastern country defined middle age as ranging from ages 30 to 59. Such variations, although modest, reflect the fact that life stages in the United States may no longer be clearly defined. The less-than-clear line of demarcation between age groups may be due to a combination of at least two factors: the contemporary United States has more life stage transition categories than any society in history, and the United States became a youth-centered society.

The variability in defining middle age is paralleled by vagueness in the behavioral expectations attached to each of these age-graded social roles. Neal Postman has pointed out that the age specificity of clothing styles is rapidly disappearing, as is the meaning of childhood as understood until the post–World War II period. His phrase, the "disappearance of childhood" is symbolized by the fact that boys on the verge of adolescence sometimes wear suits to birthday parties and men in their 60s sometimes wear jeans. The notion that you are only as old as you feel is now operationalized as you are only as old as you look to others.

The fuzziness of the borders of ages has a particularly powerful effect on the middle age, caught as they are between a socially valued youth and what appears to be a socially disvalued old age. Perhaps this is why the middle age gave birth to the midlife crisis, whereas no crises are attached to any other age category.

Death and Middle Age

Middle-aged people confront death in a number of forms common to all ages. The death of friends, pets, and siblings affect middle-aged people, but no distinctive patterns explainable by age exist. However, some forms—the death of contemporaries, anxiety about death, the death of parents, and suicide—take particular shapes for the middle age.

Death Rates and Death Anxiety

Dividing middle age into the three specific deciles used by the U.S. Census for the ages 35 to 65, the death rate in the last third, 55 to 64 is more than four times that of the first one-third, 35 to 44. Although their coming of age coincided with the Vietnam War, a disproportionate number of deaths in that war were from the lower end of the stratification system.

As more of the age cohort members of the oldest third of the middle-aged population begin to die off with some notable increase, and people nearing the end of middle age (55–64) experience the deaths of their parents, death anxiety or fear of death declines through middle age and into old age. The fact that, to a great extent, the culture of the United States is still death denying, and also the fact that a sense of invincibility is carried over from adolescence into adulthood offer a partial explanation for this apparent insulation from death anxiety.

The Trials and Death Experiences of the "Sandwich Generation"

Middle-aged people often find themselves caring for children under 18 and for parents over 65 while also handling the obligations of their careers. Caught between the dependence of two generations, the middle-aged group is often described as the "sandwich generation." By the third decade of middle age, virtually all of their children have passed the age of 18, with the majority attending college.

After age 65 and when the overall health of the parents of the middle-aged group generally declines, their parents' dependence generally increases, and the death of their parents becomes an even more likely event. Perhaps the decline in death anxiety is

also explicable in part because of the middle-aged group's witnessing the oftentimes extended decline of their parents, followed by their isolation in institutions, which encourages the anticipatory grief that many experience.

Middle Age and Suicide

In the three decades that constitute the government's statistical definition of middle age, the suicide rate rises, peaks, then falls, and continues to fall in the 65 to 74 decile, and ultimately peaks again for all age groups over 75. The most consistent increase from 1995 to 2005 was in the 45 to 54 decile.

Although there is no agreement among suicidologists on the reasons for this increase, it is useful for understanding this increase to place the 45 to 54 age group on a timeline in relation to careers, marriage or the failure to marry, and to their generation experiences, such as changes in the economy. In trying to explain the increase in youth suicide, the sociologist Menno Boldt suggested that instead of focusing only on possible increases in the pressures on young people, the possibility that there may be less resistance among the young to committing suicide may also be operating. That is, research supports the contention that suicide may be a more acceptable option for the young.

The combination of increased pressure and diminished resistance may be true for the middle age as well. Economic vicissitudes may cause career changes to become more common in that age group with retirement a long way off, and, as traditional marriages become less common among their role models, the young, social pressures may reach critical mass in middle age. With euthanasia now tied to the idea of a dignified death, and with the cultural emphasis on the importance of the individual, one effect of which is the de-emphasis of the importance of the community, and, as a consequence, the weakening of ties to the community, the ability to weather adversities may be attenuated. Suicide may seem a less onerous alternative, particularly as suicides in their own age group become more common. In sum, less resistance to suicide rather than increased pressures pushing people over the edge may apply as well to that second third of the middle-aged population as it does to the young.

In conclusion, death intrudes on the lives of the middle-aged people in many forms. They experience the deaths of contemporaries, particularly in the last third of middle age. There is a rise in the suicides of contemporaries. They experience the deaths of their parents. Placing the current generation of middle-aged people in historical perspective, they were the baby boomers who were treated as the "chosen" generation to whom things like death, or anything untoward, shouldn't happen.

In addition to being caught between dependent children and dependent parents, this particular generation of middle-aged Americans represents the so-called sandwich generation in two other senses. First they are caught between the social value of youth and the stigma of old age. In addition, the middle age is psychologically equidistant between Sir Thomas Browne's dictum that "The long habit of living indisposeth us for dying" and the practical sense of Julian Huxley, H. G. Wells, and G. P. Wells's perceptive observation in their book, *The Science of Life,* that the young desire personal immortality, not the old. As they grow older, their view may shift to this latter wisdom. On the other hand, perhaps as they have done so many times before, the baby boomers will prove their chroniclers wrong.

Military Executions

This entry focuses on the who, offenses, place, number, how, and by whom of U.S. military executions. These are deaths that have been imposed on U.S. military personnel because of misconduct and behavior in violation of military codes of conduct. In most instances, the executions resulted from unanimous jury decisions that were reviewed and approved by military judges. Nearly all of the information is from the American Revolution, the American Civil War, World War I, and World War II—no U.S. soldiers were executed during the Korean or Vietnam Wars.

Historical Background of Military Executions

Lower Ranks

Those executed from the American Revolutionary War through World Wars I and II came primarily from the lower ranks of volunteers and draftees of noncommissioned personnel. There is one notable exception. A 1919 dispatch from Dijon, France, reported that the American army authorities at Is-sur-Tille hanged an American Lieutenant for an assault on a little girl.

Because the U.S. military was segregated until 1948, race illuminates much about who was executed during the 20th century. During WWII, nearly 80% of the 70 soldiers executed in the European Theater of Operations were black, even though they comprised approximately 10% of the troops. The exact racial distribution of the 35 American WWI executions between April 6, 1917 and June 30, 1919, is unknown. However, 25 of these executions took place within the United States, and 17 involved black soldiers. Thirteen of the 17 were executed in August 1917, for participating in a riot in Houston, Texas. During the next year (1918) 3 more black soldiers were hanged for assaulting a 17-year-old white girl. Eleven more soldiers were executed during WWI in France, 8 (73%) of whom were black.

Type of Offenses

Throughout our history, soldiers have been executed for crimes specific to the military, (e.g., desertion, mutiny, and/or cowardice). They have also been executed for misbehavior defined as felonies by civilian authorities that are also prohibited by military law—murder, rape, and murder and rape together. During the American Revolutionary War, General George Washington approved hundreds of executions, some for desertion. On April 23, 1779, two soldiers were shot at Washington's Morristown, New Jersey, camp for repeated desertion. During the American Civil War, more than 275 men were executed for military offenses by the Union Army, whether guilty or not. More than half of these deaths resulted from desertion; some of the others included cowardice. No soldier was executed for desertion again until WWII. During WWI, no soldier was executed for a purely military offense, leading one army colonel to conclude that this was evidence of the good conduct and discipline of the American soldiers who served abroad. The U.S. Army has executed no soldier since 1961, when a black trooper was hanged for raping an 11-year-old white girl in Austria.

During war and peace, U.S. military executions have almost invariably been held at military installations. General Washington's executions are thought to have occurred outdoors on parade grounds at military camps or forts. The same practice appears to have been followed by the Union Army. The major purpose of these executions was discipline by example.

The place of death for each of the 35 WWI executions is unknown, but at least 17 of the U.S. deaths were outdoors, within the confines of a military camp before several, if not all, of the soldiers stationed thereby. An exception to this practice took place in Gievres, France, when a white soldier's execution for murder took place in secrecy to avoid causing a disturbance in a nearby camp.

During WWII, 18 American soldiers were executed in England for offenses committed in Ireland, England, and Wales. Except for two soldiers who were shot, each of these men were hanged. WWII executions in France occurred at one of two places—either inside a military prison if the victim was a member of the military or semipublicly at or near the scene of the crime if the victim was a civilian, depending on the conditions of war.

Selection Processes

With few exceptions, U.S. military executions have resulted from trials instead of command-ordered

field executions, mass executions, or lotteries. One notable exception occurred during the Civil War. Confederate partisan leader, John Singleton Mosby, used a lottery to select 7 out of 27 Union soldiers to be executed without trial. His action was in retaliation for a similar execution of seven members of his command by members of the Union Army.

To date, army executions in American history have relied on hanging and shooting—the needle has yet to be utilized. Hanging has traditionally been considered the more ignominious method because its death causes greater suffering and is less instantaneous than shooting. During the Civil War, the Union Army used both methods of death almost equally for murder and rape. Soldiers convicted of desertion, pillaging, spying, and mutiny were almost always shot. Of the approximate 1,112 soldiers executed for desertion from the Union Army, 100 (89%) were shot.

During WWI, the U.S. Army continued to use the rope for nonmilitary offenses—each of its 11 executions were accomplished by hanging. This method was used predominately throughout WWII. Only 6 of the 70 soldiers executed in the European Theater of Operations were shot. Desertion during WWII, although potentially a death offense, was always punished with imprisonment or dismissal, with one famous exception—Private Eddie D. Slovik, a white soldier who was killed before a firing squad.

No more than 17 American sailors and marines have been executed since 1849—significantly less numerous that army executions. But there was another capital shipboard crime. Sodomy, though not a capital offense today, prior to 1861, was a death crime in the British Royal Navy. No American soldier has been executed for sodomy, but many have been court-martialed and dismissed for this behavior. Shipboard executions of sailors and marines have always involved hanging, with one notable exception. In Richard I's 1190 C.E. ordinance of six offenses to which the crusaders would be subject, two carried punishment by death. When someone slayed a man on shipboard, they were bound to the dead man and thrown into the sea. If the killing occurred on land, the offender would be bound to the dead man and buried in the earth.

During and after the Revolutionary War, soldiers have been put to death by U.S. military personnel with two well-documented exceptions. Before the U.S. Army developed its own hangmen in WWII's European Theater of Operations (ETO), it relied upon the professional skills of two of England's Home Office official civilian hangmen, Thomas and Albert Pierrepoint. Firing squads, though relatively rare, comprised noncommissioned enlisted men commanded by an officer. Hangmen, by comparison, were with some regularity prison commandants with officer rank. The interment of the 70 soldiers executed in the ETO and the combined 26 put to death in the North African Theater of Operations (NATO) and Mediterranean Theater of Operations (MTO) illustrate that ignominious deaths suggest ignominious burials. The 18 American soldiers executed in the Shepton Mallet prison in Bath, England, were at first interred in unconsecrated land located "backstage" on the outside perimeter and adjacent to toolsheds and a compost heap in the large Brookwood Cemetery, London. Those executed in France, Algeria, and Italy were also initially buried in graves separated from those who had died honorably.

At war's end, most of these executed soldiers were exhumed and reinterred in a walled-off, secret section of the World War I Oise-Anise American Cemetery, Fere-en Tadenonis, France. A few, approximately five, were sent home to their next of kin. The executed deserter, Eddie Slovak, was returned in 1987. The final place of burial for all of the other executed U.S. soldiers during WWII include 20 at the Post Cemeteries at Clark Air Force Base, Luzon, Philippine Islands, 25 at various Post Cemeteries within the United States, and 5 at the Schofield Barracks, Hawaii. Six executed soldiers are buried in private cemeteries in the United States.

The U.S. Army executed relatively few of its soldiers in the last century compared to Great Britain and France. During WWI alone, France executed approximately 600 soldiers, most for mutiny and desertion. Britain put to death 350 during WWI. The U.S. Army has carried out at least 459 executions since the last navy execution in 1849. In the 20th century, the U.S. military terminated approximately 160 of its soldiers—none by summary execution, though rumors and allegations claimed otherwise and resulted in official investigations.

Future of Military Executions

One of the more striking features of first-world nations in the Western world during the last 100 years

has been the abandonment of the power to execute citizens. This raises interesting and perplexing questions about the future of intra- and inter- as opposed to extra-military executions. Put simply, will militaries continue to execute their own members? At issue is whether the time-honed argument that the military is a unique institution whose emphasis on efficiency through discipline requires the availability of executions as an essential element of social control, especially during war. Clearly the mounting evidence suggests the contrary.

Because inter- and intramilitary executions are extremely rare, it is difficult for its proponents to point to the use of executions as an efficient tool for discipline and deterrence. Of the 266,785 British soldiers convicted of military offenses during WWI, for example, only 2,675 were sentenced to death and only about 10% of this number were actually executed. The United States has not executed a soldier for a military offense in nearly 60 years. Great Britain, too, has not executed a solider since before WWII.

Furthermore, there is no empirical evidence that there is any difference in the efficiency or effectiveness of fighting armies because of the use of the military executions. During WWI, the Australian armed forces fought bravely and effectively, and did so without having the burden of high-level formal discipline and without a deterrent death sentence for misconduct such as desertion.

Abandoning Military Executions

There is little doubt that the world has learned more about military executions during the 20th century than at any other time. The reasons for this historical point are that its wars, especially World Wars I and II, are relatively recent, well documented, often controversial, and interesting enough to a number of broad audiences to encourage ongoing amateur and professional research. One important contribution to the military execution knowledge base in recent years has been the addition of Internet websites that are devoted to military executions and civilian capital punishments. Despite their popularity, many of these websites contain incomplete and/or misleading information. But the popularity and current interest in military executions is expanding, in part because with the benefit of hindsight and close examination, past executions are increasingly understood as an integral part of the great human tragedy—war.

Miscarriage and Stillbirth

Pregnancy loss is a surprisingly common occurrence, but often goes unrecognized, unregistered, or unacknowledged. Medically, fetal death represents a challenge to the worldwide goal of reducing child mortality. Psychosocially, the death of a child before birth, because it represents neither the entry of a new person into society nor the departure of a recognized member of the social order, presents unique challenges to the grieving parents.

Definitions

Miscarriage, or spontaneous abortion, is defined by the World Health Organization (WHO) as a fetal

death in early pregnancy. Stillbirth is defined as the death of a fetus late in pregnancy, during the perinatal period, from 22 weeks gestational age through 7 days postpartum. Individual countries rather arbitrarily define the gestational age at which a pregnancy termination is classified as either a miscarriage, early stillbirth (typically 20–28 weeks gestation), or late stillbirth (after 28 weeks). Some industrialized countries classify death at 16 weeks gestation as a stillbirth. If the gestational age is unknown, a birth weight of 500 grams is often used to make the distinction between miscarriage and stillbirth. Stillbirths are also often classified as antepartum (before the onset of labor) or intrapartum (during labor). This variation in the classification of miscarriage or stillbirth makes epidemiological monitoring and intervention difficult.

Rates

About 15% to 20% of pregnancies result in miscarriage, the most common complication of early pregnancy. The rate is much higher if one includes pregnancies that end within six weeks of the last menstrual period, often before a woman is aware of the pregnancy. Eighty percent of miscarriages occur within the first trimester.

Approximately 5% of first pregnancies end in miscarriage. Most women who miscarry go on to have successful pregnancies, but about 1% of women have recurrent (more than three) miscarriages. The risk of subsequent miscarriage or stillbirth increases with each prior stillbirth or complicated pregnancy. The rates of twin and multiple births have increased in the past two decades, associated with growing use of assisted reproductive technologies. The risk of stillbirth is four times greater in multiple pregnancies than in pregnancies with just one fetus.

The WHO notes a worldwide incidence of stillbirth at 3.9 million, with about 26% of those stillbirths occurring during the delivery of a mature fetus. These figures are generally thought to be underestimates because most births in developing countries occur in the home and information is not reported. The rate of stillbirth in developing nations is 10 times greater than in the United States. The most recent figures reported by the WHO estimates the stillbirth rate in the United States as 3/1,000, on a par with the figures reported for Canada, Australia, and much of Europe.

Causes

Miscarriages may be the result of chromosomal abnormalities, progesterone deficiencies, uterine malformations or infections, or uncontrolled diabetes. However, most causes of miscarriage are unknown and thought to be unpreventable.

It is difficult to obtain data on the causes of stillbirth because of a lack of uniformity in protocols for classification of stillbirth and the declining rates of autopsies. Where protocols are available, it is found that the most common causes of stillbirth between 24 and 27 weeks' gestational age are infection, placental problems, or fetal malformations. Between 25% and 60% of stillbirths are due to unknown causes. Death during labor is rare in the developed world, but in developing countries as many as 1 in 100 babies die during delivery. It is presumed that access to good obstetric care could prevent these deaths, as well as late stillbirths due to maternal/fetal infection.

In the United States, the most prevalent risk factors for miscarriage and stillbirth are first pregnancy at a young age, advanced maternal age, obesity, and high blood pressure. Access to prenatal care decreases the risk of fetal death, and in the United States, social and demographic factors associated with limited health care availability (poverty, minority status, rural residency) are important risk factors. African Americans have a higher risk of stillbirths. Other risk factors include smoking, and alcohol or cocaine use during pregnancy.

Physical recovery following miscarriage or stillbirth is often relatively uncomplicated. However, psychological recovery is far more complex. There has been little or no research on the psychological impact of miscarriage and stillbirth on the mother in developing countries, where stillbirth and miscarriage are common pregnancy outcomes. In the United States, most cultural groups highly value children, and the death of a child is considered a profound tragedy and an occasion for mourning. The death of a child before it is born, however, presents a unique bereavement situation.

Grieving Pregnancy Loss

The birth of a child is a highly anticipated event. Almost from the moment of conception, parents-to-be form idealized expectations of what their child will be like. With the routine use of ultrasound

imaging, the fetus becomes real to the parents, and a parental bond is formed long before the actual birth. In the event of a miscarriage or stillbirth, parents are mourning at a birth. Despite reassurance that the miscarriage or stillbirth was unpreventable, the mother often blames herself for her body's failure to carry a child to term.

The course of grief following stillbirth and miscarriage is variable. Anxiety and depression are common in the first few months after the loss, but some people experience little distress even as soon as two months postloss. Most symptoms of anxiety and depression dissipate over time, but some parents remain distressed for years following the loss. Within a couple, it is most common for one partner, not both, to be distressed.

An interesting paradox is that while friends and relatives celebrate pregnancy and eagerly anticipate birth, a pregnancy loss is barely acknowledged. There is a strong cultural taboo in America against recognizing the psychological significance of miscarriage and stillbirth. In the climate of silence surrounding pregnancy loss, funeral rituals following miscarriage are not common, and cultural practices may prohibit ritual burial of a preterm infant. On the other hand, significant changes to hospital protocol following a stillbirth promote memorialization. It is now routine hospital psychosocial practice to offer the parents photos of their stillborn child and tangible mementos, such as locks of hair, footprints, ID bracelets, blankets, and so forth. Parents treasure these objects as tangible representations of a real baby that died and as a continuing bond with their dead infant. In addition to offering mementos, many hospital bereavement teams encourage parents to see, hold, and interact with their stillborn infant. A recent series of studies suggests that this latter practice may be associated with heightened anxiety and depression during a subsequent pregnancy and with disordered behavior in the subsequent baby.

As with most unanticipated traumatic events, a crisis of meaning is created. Memory is often disrupted, and there is a need to tell and retell the story of the loss of the pregnancy until it makes sense. Parents must create a new life narrative, different than the one they had expected. Pregnancy loss social support groups have been developed in recent decades to provide a safe forum where grieving parents can shape their stories and remember and memorialize their dead babies. These support groups rely heavily on the use of shared rituals and written expression to alleviate the commonly voiced fear that the parents will forget their baby. More recently, the Internet has provided a virtual forum for memory and shared support through pregnancy loss websites.

While many expectant mothers who experience stillbirth and miscarriage are greatly distressed at the loss and at their body's inability to successfully complete a pregnancy, most are determined to try again. Fortunately, most women who miscarry go on to have healthy babies. While medical advice is that it is safe to conceive shortly following miscarriage, psychologically it is more complex and there is no one right answer. There is likely to be heightened anxiety during a subsequent pregnancy.

Helping After Pregnancy Loss

There is no one right way to grieve. Hospital personnel should be aware that cultural norms regarding bereavement and emotional expression differ, and they should be sensitive to the variety of initial reactions to the loss. While nurses might gently offer the parents the opportunity to hold their baby if they wish, this option should never be forced upon parents. In general, hospital personnel, friends, and family should respect and honor parents' individual wishes and cultural practices, acknowledge the depth of the loss, and be available to listen with sensitivity and compassion, and without judgment, as parents reshape the narrative of their lives.

Missing in Action (MIA)

MIA is the abbreviation for missing in action and is used to describe a member of the armed forces who has been reported missing after combat operations. The service member may be injured, captured, or even dead, but his or her status is unknown. The term MIA was originally coined in the United States, and it is still used primarily by Americans. However, this abbreviation was not used until 1946 (just after the end of WWII). Those designated as MIAs must not have been accounted for in any way, that is, they must not be reported as killed in action (KIA) or captured as a prisoner of war (POW).

In many ways, the status of MIA, because of its ambiguity, is known to be more devastating to family members and friends than KIA. At least when people are confirmed dead in combat operations, there is a sense of closure that does not exist for those left to wonder about the fate of their loved ones.

Incidence

Although the term MIA did not come into existence until 1946, the U.S. Armed Forces have always had members with MIA status in all armed conflicts. For example, it is estimated that American MIAs from the Revolutionary War numbered about 1,426; from the War of 1812 about 695; from WWI some 4,452; from WWII 78,773; from the Korean War approximately 8,100; and from the Vietnam War 1,763. In the Iraq War, or Global War on Terror (GWOT), two members of the United States military are MIA. In the GWOT, there are also American civilian MIAs based on their work on behalf of civilian nonprofit groups, civilian contractors, and reporters working with the military in Iraq and Afghanistan. The reduced number of MIAs in America's more recent conflicts (Vietnam and the GWOT) is due to better evacuation of troops immediately following combat operations. Thus, fewer personnel were ever left behind after a battle and even the seriously wounded can be carried off with their comrades. Although there were relatively few MIAs in Vietnam, the term MIA became most prominent after this war in Southeast Asia.

The Politics of MIA

The term MIA began to take on a political meaning after the Vietnam War. The war had been politicized in the late 1960s and into 1970 to 1972. In the United States, people became more polarized over the issue of Vietnam and eventually, the majority of Americans wanted the U.S. military out of this conflict.

When the Paris Peace Accords were signed between the United States and North Vietnam in 1972, the North Vietnamese stated that they still held 591 POWs, many of whom had been listed as MIAs. Within a few months, all 591 were repatriated to the United States. Yet, many Americans believe that many more MIAs were held by North Vietnam in hopes of negotiating for financial settlements from the United States. It is also believed by many that the remains of other MIAs were also held back by the Vietnamese government again in hopes of ransom. There are those who believe that through the 1970s, 1980s, and even into the 2000s, some former American MIAs were and are still alive in Vietnam.

Identifying MIA Remains

In 1973, soon after the Paris Peace Accord was set in place, the U.S. Department of Defense

established the Central Identification Laboratory in Thailand to serve as a coordination center for POW/MIA recovery efforts throughout Southeast Asia. It was hoped that this would serve as a center for information on MIAs. By 1976, another Central Identification Laboratory was established in Hawaii to aid in searching for and identifying remains of MIAs from previous wars. A Joint Task Force Accounting Project was then established to achieve a full accounting of Americans missing from the Vietnam War. In 2002, the U.S. Department of Defense determined that the two identification laboratories should be combined with the Joint Task Force. By 2003, the Joint POW/MIA Accounting Command (JPAC) was established under the Commander of the United States' Pacific Command. JPAC utilizes 18 recovery teams that travel around the world in an attempt to recover MIAs or their remains from past wars.

MIA and Social Activism

The determined effort to find MIAs, especially from Vietnam and the rest of Southeast Asia, is the result of the effort of many groups throughout the United States that have taken up the cause of Vietnam-era MIAs. The largest of these is the National League of Families of American Prisoners and Missing in Southeast Asia. This group was established in the 1960s and incorporated in the nation's capital, Washington, D.C., in 1970. Its emblem, a black flag with the white silhouette of a man next to a guard tower, is well known throughout the United States. Above the silhouette are the words "POW*MIA" and underneath the words, "You are not forgotten." This flag is flown outside a number of American homes and at major U.S. institutions on the public holidays of Veterans Day and Memorial Day. This league has also distributed hundreds of thousands of identification bracelets each inscribed with the name of a Vietnam-era MIA. The mission of the league is to secure the release of all prisoners of war, to account for the missing, and to return the remains of American decedents of the Vietnam War.

Another large nonprofit agency dedicated to POWs and MIAs is Rolling Thunder, Inc. Its members include many motorcycle riders who have staged rallies in Washington, D.C., each Memorial Day weekend since 1987. The mission of Rolling Thunder is raising the public's awareness of American soldiers who are prisoners of war or are missing in action. On Memorial Day 2007, the 20th such Rolling Thunder rally, hundreds of thousands arrived in Washington, D.C., under the banner "We will never forget."

MIA Records

The Library of Congress maintains a database of some 147,000 records pertaining to missing Americans from Southeast Asia. Much of what is contained in this database are records of the U.S. Senate Select Committee on POW/MIA Affairs. This committee was established in October 1991. According to the Library of Congress, the committee's tasks included, among others:

- To determine whether there was evidence that there were other MIAs from Vietnam who had not been returned by Vietnam and to determine if there was evidence that some may have been alive in captivity.
- To ensure the adequacy of government procedures for following up live-sighting reports and other POW/MIA related information.
- To demystify the POW/MIA accounting process so that the families and the public can better understand the meaning behind the numbers and statistics used in discussions of the issue.

The committee's final report found that there was no credible evidence that any POW/MIAs from Southeast Asia were still alive in that region of the world. This information was not welcome news to many families of MIAs, as they had clung to hope that their loved ones were still alive.

MIA-Related Research

A great deal of research was carried out with families of MIAs from the Vietnam War to discover how the wives and children were coping with the task of continuing on while uncertain as to whether their husbands or fathers were still alive (all the Vietnam era POW/MIAs were men). The families of MIAs live in a state of chronic stress because there is no closure with respect to their husband or father. Such families have been

described as experiencing "unresolved bereavement" and "prolonged ambiguous grieving." They do not have a clear understanding of their loss as one would after the death of a loved one. This ambiguous loss has many negative effects on the wives and children of MIAs. There is discussion of the difference between the physical presence of a husband or father and his psychological presence. The families of MIAs have only the symbolic presence of the husband or father figure; his physical presence is no longer real and yet there is often hope of his return.

In interviews carried out about two years after the husband or father had been declared MIA, mothers reported that about 20% of their children had behavioral problems, such as frequent crying, nightmares, acting out, shyness, and fear of the dark. Fewer than half of these children received any professional help. Those children who had actual memories of their missing father had the most severe problems. Even in studies 20 years after the MIA status of the father, some of the now adult children of MIAs still had problems with intimate relationships. There were several common themes played out in the lives of these adults whose fathers had been declared missing in action while they were children. These themes include fear of abandonment, feelings of depression, lack of trust in others, feelings of anger, and a fatalistic attitude toward life.

The one fact that stood out in all of this research is that the mothers' adjustment was the major predictor of children's psychological well-being. Mothers who carried out the roles that their husbands would have played (in addition to their own) had the children with the fewest problems. Mothers who went on with their lives: going out of the home to work, continuing on with interrupted education, and recognizing that the husband/father might not return, and that the family had to cope without him, were the best adjusted, as were their children. The mothers who kept the psychological or symbolic presence of the husband/father in the forefront of family life were the least well adjusted, as were their children. In spite of the fact that these "coping" mothers had their own unresolved grief, they tried to make the lives of their children as normal as possible. Mothers who had remarried had adult children with the fewest problems. The Department of Defense (DoD) now provides training for all military and civilian members of the DoD in personnel recovery. This training alerts their members to the difficulties of those who are "isolated, missing, detained or captured" after combat operations. So it now may be true that "we will never forget."

Monuments

Monuments commemorate a person or an event in history. In relation to death, monuments are built in tribute to the dead, in honor of victims of war and accidents, or as efforts to immortalize someone's deeds and ideas. Monuments are an attempt to rescue a person, group, or event from anonymity, and they help keep survivor's memory alive. The idea of perpetuity is supported by the materials that are often used for monuments—bronze, granite, marble, iron—that withstand the ravage of time, but monuments can also be made out of less permanent materials, such as wood, or made out of living materials. Monuments connect the present with the past. They evoke personal memories, but equally important, they help groups to remember their past.

Growth of a Commemorative Culture

The erection of monuments for commemorative purposes is found in all historical periods. For instance, the pyramids of ancient Egypt are mausoleums built for the enduring commemoration of the deceased. Another example is the roadside grave or memorial that marks travel-related death and which is an act of commemoration that dates back to ancient times. Prehistoric traders of amber, flint, and freestone in central Europe often buried their dead alongside the road. In ancient Rome, mausoleums were built at the street side where the fatal accident occurred. The increasing number of monuments in Europe and the United States, however, and the urge to record events of death at its contemporary rate is a rather new phenomenon. The start of a commemorative culture is hard to fix, but World War I, with its industrial mechanization of death, was one of the first instigators to a collective need to remember. Wars in 20th century reach farther—geographically and socially—than that of earlier, nonindustrial conflicts.

In addition to the two World Wars, the interest for the past and the recollection of memory extended under the influence of several factors. First, the fast modernization after World War II that resulted in the decline of traditional life forms led to a nostalgic longing for a lost world. Second, the increased prosperity and the growing leisure time stimulated the emergence of a commemorative culture. Third, European unification and the process of globalization that leads to an increased interest in a nation's past and the affirmation of national identities also fuels commemorative culture. The search for and affirmation of social and political identity follow important breaks in history, like the French Revolution of World War II. Another reinforcement of the flowing number of monuments we find in the study of roadside memorials in which the construction of monuments is seen as a response to sudden and tragic death in a society where death has been removed from everyday life.

The Range of Monuments

A distinction can be made between the creation of a spontaneous memorial and the construction of an official monument. Memorials are often constructed immediately after death occurs and are an expression of grief over the death of particular people. For instance, immediately after the death of Princess Diana in 1997, the public left thousands of flowers and other tributes outside the gates of Kensington Palace. These spontaneous acts of commemoration are often followed up with official monuments constructed by an artist at the initiative of survivors and authorities. Several monuments were constructed over the years for Princess Diana. One of them is the Diana, Princess of Wales Memorial Fountain in Hyde Park, London, which aims to reflect Diana's life and symbolizes her qualities. The function of a monument extends beyond the expression of grief; they become reflections of someone's life, bearers of national histories, communicators of political messages, and places of collective memory.

Another distinction can be made between individual monuments and collective monuments. Examples of individual monuments are tombstones, mausoleums, or statues picturing a famous figure. Individual monuments, however, can become part of a collective need to remember. For example, the grave of Jim Morrison in the Paris graveyard Père-Lachaise, and the burial plots of national heroes, musicians, and writers all have become places of worship. Collective monuments memorialize a connected group of deceased (e.g., war victims and veterans) or an event that caused

many deaths (e.g., an airplane crash and September 11, 2001). Although these monuments have a collective purpose, the loss of individuals can be remembered through the victims' names, which are written on monuments.

Monuments tell the story of a deadly event or the person that died, unveiling the cause and circumstances of death. This story is often literally and symbolically translated in the design of the monument, texts written on plaques, and monument location. The United Flight 93 Memorial Sculpture and Garden in Shanksville, Pennsylvania, is an illustrative example. On September 11, 2001, when United Flight 93 crashed, students from a nearby school and the small community of Shanksville supported the rescue workers in many ways; they bottled water, prepared sandwiches, and offered shelter. In the recollection of this event, the helping hands of the community emerged as a powerful image of what happened. The artist, who was commissioned to create a monument in honor of the victims, the students, and the community, took her inspirations from this image. The sculpture appears as a form rising from the ground with pods that bear many hand imprints. The sculpture is located in a garden adorned with nine large stones, bearing quotations from famous Americans, which inspire patriotism, courage, and self-sacrifice that were evident this September day.

Collective Memory and Identity

Monuments serve the individual memory and grief of the people who are directly involved: survivors, witnesses, and the bereaved. Collective expressions of loss help individual bereaved accept the fact of death. More important, monuments as anchors of memory have a collective and public function. Through the monument, memory is extended in time and range beyond the memory of the people who are directly involved. Monuments are often built on a location of historical or symbolic interest, frequently marking the place where death occurred. Being landscape markers, monuments are part of the *lieux de mémoire*—sites of memory—of a group of people or a nation. Monuments form the boundary stones of another age according to historian Pierra Nora, who introduced the concept of places of memory. Lieux de mémoire are places where people can identify with their past. Along with museums, archives, cemeteries, festivals, anniversaries, and sanctuaries, monuments serve the construction of a cultural memory.

The cultural memory of a nation determines the collective and individual remembrance of a society's culture and is the basis on which national identity is constructed.

Nora argues that lieux de mémoire originate with the sense that there is no spontaneous memory; memory is a social and cultural construction. A cultural memory cannot embrace all individual memories, and its construction is always a selecting and generalizing process. There will always be groups whose stories are excluded from the dominant discourse. Elite groups and political authority have a powerful hand in the construction of a cultural memory. They use public space, of which monuments are part, to communicate to the public a particular kind of national or cultural consciousness. For this purpose, public monuments are the most conservative of commemorative forms, precisely because they appear unchangeable and are meant to last forever. Portraying only selective parts of a nation's history, monuments determine the way people remember and how they shape their national identity.

Monuments embody a multitude of memories, emotions, and messages. They can tell a message of honor, respect, complaint, sacrifice, hope, and protest at the same time. The construction of memory through monuments and the attachment of meaning to monuments are not univocal. The past, rather than be preserved as some objective record, is always being constructed and reformulated in the context of the present. Contesting perspectives on the monument are of different natures, about the esthetical judgment or the emotional or political value. Many monuments, however, do generate shared or widely held interpretations. They not only project the intended meanings of their constructors, but the interpretation of them by its visitors is facilitated by dominant ideologies in society.

Monuments, being focal points for memory, are often the locus of rituals. They are sites where commemorations are performed and collective memory is reinforced. Liberation days, for instance, are celebrated at the national war monument. The repetition of these national and collective rituals at a particular monument emphasizes the importance

of this site as lieux de mémoire. Moreover, visits to war monuments such as the Vietnam Veterans Memorial and the Cimetière du Père-Lachaise in Paris are popular. The nature of these visits ranges from tourism to pilgrimage. Monuments induce emotions and expressions of grief and remembrance in the form of letters, flowers, and candles can be found near roadside monuments, on graves, or at the foot of a famous statue. The performance of commemorative rituals near monuments articulates and reformulates the meanings that are inscribed in the monument. Collective memory is constructed and reinforced in these performances.

Remembrance induced by monuments is not only aimed at the recollection of the past and the reinforcement of memory. Mainly when they are associated with war, violence, and accidents, they are increasingly connected with a concern for the present and the future by way of asserting the hope and making the promise "this may never happen again."

Transformations of Monuments

Although a monument seems to be static and permanent, the meanings attached to it and even its outlook can transform over time. The adding of new plaques and new monuments to older ones give insight into a power struggle that takes place at some monuments, for example, the struggle of relatives for rehabilitation of British World War I soldiers who were shot for cowardice. These soldiers, traumatized by the experiences of war, tried to escape their war duties, resulting in their execution. It was more than 90 years after World War I that these soldiers were publicly acknowledged as war victims. By that time some of their names were finally included in the long lists of names on World War I monuments. Another illustrative example is the construction and reconstruction of the Vietnam Veterans Memorial. The initial design was that of two black granite memorial walls on which the name of the 58,000 men and women who died in service were written. It lacked any reference to patriotism and national symbols. Later on, the American flag, a heroic statue picturing three soldiers, and the inscription "God Bless America" were added to the walls in order to meet the wishes of the public. The contrast between expressions of patriotism, on one hand, and on the other hand, personal grief, is still vivid and visible at this monument.

Societal developments and changing perspectives on the past and present are reflected in commemorative acts and reconstruction of monuments. New wars are commemorated and new war victims are honored at liberation days. In other occasions, monuments fall into disrepair over the years as soon as their significance passes into oblivion and their function decreases. The cultural memory of a nation is nonstatic and nonpermanent and transforms along with the monuments.

Monuments are material things: seemingly static, unchangeable structures in the public space that are intended to last forever. However, they are dynamic, and it is their ability to communicate a multitude of messages that determines their importance in public space. They evoke specific kinds of emotions and meanings, and they serve as spatial coordinates for individual and collective memory.

Mortality Rates, Global

There are major differences today in the mortality rates of the countries of the world. Babies born in Japan or Sweden live much longer than those born in Botswana or in Lesotho Southern Africa. Why do these differences in life expectancy exist among countries? Levels of development, medical conditions, and a host of other factors are involved.

The major causes of death are not the same in countries with high and low levels of life expectancy. There have been changes over time in the major causes of death. People used to die mainly of infectious and parasitic diseases, but the major causes of death today in developed countries such as the United States are heart disease and cancer. In this entry, we discuss these and related issues.

Historical Evidence

Our knowledge of mortality levels and conditions prior to the Industrial Revolution is incomplete. We know that mortality was high then, but the availability and completeness of the death data leave a lot to be desired. According to Scheidel, age data from census records of Roman Egypt indicate an average life expectancy at birth in the 1st to 3rd centuries C.E. of between 22 and 25 years, a finding corroborated by data on tombstones in Roman North Africa. As late as the 18th century, life expectancy ranged from only 30 to 40 years in much of Europe and the United States. Males in the United States in 1901 had a life expectation at birth of 47.9 years, and females, 50.7 years.

Causes of Death

The eminent demographer Donald Bogue has noted that death is caused by a number of reasons and diseases, which require the understanding of the etiological factors of the major causes of death. Data on the causes of death, even today, are far from complete. Some deaths around the world are not even registered. In many countries, a large proportion of deaths occur outside the presence of a physician, and the cause is either unknown or incorrectly diagnosed. Often the cause of death is misrepresented or camouflaged if it is socially unacceptable, such as suicide, syphilis, or HIV/AIDS.

Moreover, international comparisons of cause-of-death data are difficult because countries often differ in terminology, method of certification, diagnostic techniques, and the quality of the coding and data collection system. Nevertheless, some generalizations are possible about the general structure of cause of death in the contemporary world.

Death is a complex behavior, and there are literally many thousands of ways to die. But some causes of death occur more frequently than others. For instance, the World Health Organization reports that in 2002 there were approximately 57 million deaths in the world. The top cause of death throughout the world was cardiovascular disease; coronary heart disease accounted for 7.2 million deaths, and cerebrovascular disease and stroke accounted for another 5.5 million deaths.

People around the world, however, do not all die of the same major causes. There are differences, and these are largely due to the socioeconomic levels of the countries. The World Health Organization has developed an illustrative example. Consider a hypothetical population of 1,000 people to represent all the women, men, and children around the world who died in 2002. Of these 1,000 decedents, 138 of them will have come from rich countries, 362 from middle-income countries, and 501 from poor countries. For each group of countries, the distributions of deaths are not identical, nor are they ranked in the same way.

Concerning the 138 people from the rich countries, coronary heart disease is the cause of 24 of the deaths, 13 will die from stroke, and 8 from lung cancer. HIV/AIDS is not one of the major causes of death in this group of countries. Less than 15% of the population of the world lives in these countries, and they account for only 7% of all the deaths.

In the middle-income countries, nearly one-half of the people live to age 70, and the major causes of death are the chronic diseases, just as in the rich countries. The difference, however, is the role of HIV/AIDS as a major cause. Of the 362 deaths to people from the middle-income countries, 54 will have died from stroke or other cerebrovascular diseases, and 49 from coronary heart disease. Twelve people will have died from lower respiratory infection and 12 more from HIV/AIDS.

In the poor countries (many located in sub-Saharan Africa), less than a quarter of the population

attains the age of 70, and nearly a third of all deaths are to children under the age of 14. Of the 501 people from these countries dying in 2002, 54 will have died from coronary heart disease, and 50 from a lower respiratory infection. HIV/AIDS will be responsible for the deaths of 38 people. Thirty-two infants will have died from perinatal conditions. Thirty people will have died of stroke or other cerebrovascular diseases.

Life Expectancy

We have noted considerable variation around the world in causes of death. Life expectancy also varies considerably. According to data of the Population Reference Bureau, in 2007, a baby born in Japan, on average, could expect to live for about 82 years; a baby born in Sweden, about 81 years; and a baby born in the United States, about 78 years. In contrast, a baby born in 2007 in Botswana and Lesotho, Southern Africa, could expect to live on average 34 and 36 years, respectively.

In the world in 2007, life expectation at birth was about 68 years (66 years for males and 70 years for females). These are averages, but for the most part, the higher the country's level of economic development, the higher its life expectancy for both males and females. In the countries of the less-developed world in 2007 (accounting for 5.3 billion of the world's 6.6 billion people), life expectancy at birth was 66 years (64 for males, 67 for females); if we exclude China (an economically less-developed country, but demographically developed with low fertility and high life expectancy), life expectancy is 64 years (62 for males and 65 for females). Compare these figures with those for the more developed countries of the world, with an overall life expectation at birth of 77 years (73 for males, 80 for females).

Changes in Life Expectancy

The United Nations in its *World Population Prospects* notes that the 20th century was the era characterized by the most rapid decline in mortality in human history. In the early 1950s, life expectation in the world was 46 years, and, as we just noted, it is now 68 years. The United Nations projects that over the next 45 years, life expectation for the world will reach 75 years. Life expectancy in the developed world is projected to increase from its 77 years in 2007 to 82 years by mid-century and 74 years for the less-developed countries.

The increases in life expectancy expected for the more-developed and the less-developed countries tend to hide the variation in these changes among the world's major areas. The trends illustrate that, on average, the countries of Asia, Latin America, the Caribbean, North America, and Oceania have been experiencing increases in life expectancy at a steady pace. Europe, however, shows a slowdown beginning in the late 1960s through the late 1980s. According to the United Nations, this is due to a decrease in life expectancy in Eastern Europe, mainly the Russian federation and the Ukraine. Other countries in Europe have among the highest life expectancies of the world. Unlike the situation in the other regions of the world, increases in life expectation since the late 1980s in Africa have been stagnant. According to the United Nations, this is due largely to the HIV/AIDS epidemic, as well as armed conflict, economic problems, and the prevalence of infectious diseases, such as tuberculosis and malaria. These trends have halted progress in life expectancy by reducing it by approximately 15 years. In the years 2005 to 2010, Africa is expected to have levels first seen there in 1990 to 1995. In 2045 to 2050, life expectancy is expected to increase to 66, but this is still 12 years below the 2007 life expectancy in the United States.

HIV/AIDS

HIV/AIDS is a major worldwide pandemic that is ravaging the world. As of the writing of this entry, the world is more than 25 years into the HIV/AIDS epidemic. Acquired Immune Deficiency Syndrome (AIDS) was first noticed in the United States in 1981. Hemophiliac cases of AIDS were first reported in 1982. The human immunodeficiency virus (HIV) causing AIDS was isolated in 1983 at the Pasteur Institute in Paris. By the late 1980s and into the 1990s, HIV/AIDS had been identified in every region of the world. HIV is spread person to person via contact with body fluids. Zaba notes that this disease can spread through sexual intercourse, blood transfusions,

from mother to child in the course of the pregnancy, delivery, or breast feeding, and even through use of unsterilized hypodermic needles and surgical instruments.

According to the United Nations Joint Program on HIV/AIDS, as of 2006 around 65 million people worldwide have been infected since the virus was first recognized in 1981, and over 25 million have died. Two-thirds of all people living with HIV in 2006 were in sub-Saharan Africa, where HIV is mainly transmitted via heterosexual sex. Although sub-Saharan Africa is by far the most affected region in the world, epidemics are also underway in Central Asia and Eastern Europe, where in 2005 an estimated 220,000 people were newly infected. It is clear that the HIV/AIDS epidemic has had, and continues to have, an impact on the populations of many countries of the world. An estimated 25 million people have already died of AIDS, and around 40 million people are now living with HIV.

The United Nations reports that HIV prevalence is estimated to be at least 1% among the population aged 15 to 49 years in the 58 most highly affected countries of the world. Four very large countries with HIV prevalence rates below 1%, namely, Brazil, China, India, and the United States, need also to be considered in this discussion because of their large absolute numbers of persons currently living with HIV, increasing the above total to 62 countries. Of these countries, 40 are located in sub-Saharan Africa, 11 are in Latin America, and 5 are in Asia. As a combined group, they include over 35 million of the around 40 million adults and children in the world who are infected with HIV, or approximately 90% of the total number of people living with HIV in the world. Eight countries, all in Africa, have astoundingly high HIV prevalence rates. Swaziland has 33.8% of its population aged 15 to 49 infected with HIV, followed by Botswana at 24.4%, Lesotho at 23.1%, Zimbabwe at 20%, Namibia at 19.7%, South Africa at 18%, Mozambique at 16.3%, and Zambia at 16.9%. Outside of Africa, no other country has an HIV prevalence rate higher than Haiti's of 3.8%.

While the spread of HIV/AIDS has played a major role in the life expectancy of some countries around the world, the trends and causes of death are likely to differ as medical progress is made and the political and economic circumstances of countries change.

Mortality Rates, U.S.

Mortality rate (also referred to as the death or fatality rate) is used to describe the ratio of total deaths to the total population in a particular community over an established period of time. It is often expressed as the number of deaths per 100,000 of the population in a given year. When thinking specifically about U.S. mortality rates across time, dramatic changes have occurred over the past 300 years. U.S. mortality rates during the colonial period are considerably different than those that characterize present-day society. Mortality rates within a given year also vary

significantly due to specific characteristics that include demographic, economic, geographic, sociocultural, and political factors. Differences based on age, gender, race and ethnicity, income, education, and occupation all serve to influence U.S. mortality rates. This entry explores U.S. mortality rates across time, and it details group-specific differences in mortality rates at certain periods.

U.S. Mortality Rates: 1600s Through 1800

Prior to 1800, there is limited information available on U.S. mortality rates; information about mortality rates during this period is often pieced together from a range of sources that include newspaper articles, government documents, speeches, public records, individual letters, and diaries. When the U.S. Census first started recording data in 1790, deaths and causes of death had not been uniformly recorded.

The early colonial period is generally characterized by a young population profile and high rates of death, affecting the young and old alike. Harsh conditions paired with the contamination of food and water, high risk of intestinal worms and infection, along with infectious disease had deleterious effects for many. Epidemics involving infectious diseases, including smallpox, measles, mumps, malaria, dysentery, scarlet fever, venereal diseases, typhus, bubonic plague, and yellow fever, are documented throughout the 17th and 18th centuries. U.S. death rates attributed to epidemics were significant during this period. For example, the smallpox epidemic, which hit Massachusetts in 1677, killed hundreds, or around 12% of the state's population.

Native Americans suffered greatly from European colonization in terms of mortality rates, with the combined deleterious effect from infectious disease, as the result of war, slavery, and genocide. And, while there is little data on African American mortality rates during the colonial period, it is widely thought that mortality rates across the life course, from infancy through adulthood, were as much as four times higher in the African American community. A wide range of factors explain these higher mortality rates, including lack of access to adequate medical care, nutrition, and shelter, paired with widespread mistreatment.

U.S. Mortality Rates: 1800s

Information on U.S. mortality rates during the 19th century is typically derived from census data. Mortality statistics based on death registrations were first published in 1850. These data are incomplete because the information was not uniformly recorded in all U.S. jurisdictions. Further insights into late-19th-century mortality rates are provided by morbidity reports on contagious diseases authorized by the U.S. Congress.

Notable changes in science, medicine, technology, and the practice of public health practices during the 19th century inspired shifts in U.S. mortality rates. While traditional religious explanations for disease, sickness, and death were in the past commonplace, this perspective was increasingly eclipsed by scientific discourse aimed at identifying and ameliorating illness, and ultimately, death. During the mid-19th century, the fields of bacteriology and microbiology gained significant knowledge, and the germ theory of disease served to link certain diseases to specific pathogens. With research from scientists like Great Britain's Edward Jenner and the French-born Louis Pasteur, vaccines were developed (based on the experimentation with disease-preventing inoculation that first occurred in China and India more than 2,000 years ago) to help prevent a number of devastating diseases, including smallpox. By the mid-1880s, the cholera organism was identified and contained. General anesthetics were also introduced during this period, which further enabled life-saving surgical interventions, as antimicrobial substances were applied to the body to reduce the possibility of lethal infection.

Despite these scientific developments, however, infectious diseases continued to serve as major health threats and were responsible for the majority of deaths throughout the 19th century. Poor sanitation, overcrowding, and unhealthy housing situations in growing U.S. urban areas are attributed to many epidemics that spread across the country during this time.

U.S. Mortality Rates: The 20th Century

The first annual report on mortality available in the United States began in 1900, with data provided by 10 states, the District of Columbia, and a number of additional urban areas. With the addition of

Texas in 1933, information on mortality rates for all of the United States was accessible.

When comparing a population across time, it is common to look at the death rates of specific age groups. Infant mortality rates, for example, are regarded as a measure of a community's overall well-being, and during the 20th century, Centers for Disease Control and Prevention (CDC) data reveal that infant mortality in the United States was reduced by about 90%. Age-adjusted mortality rates are also used to standardize the effects age has on mortality; age-adjusted rates reveal what the level of mortality would be if yearly changes in age composition of the entire population did not occur. As depicted in Figure 1, the age-adjusted mortality rates across all age groups declined significantly during the 20th century.

The age-adjusted death rate in 2000 fell to 872.4 deaths, compared with 1,446 deaths in 1950, and 2,518 deaths in 1900. The decline in age-adjusted U.S. mortality rates, based on data from the National Center for Health Statistics (NCHS), reveals life expectancy at birth in 1900 was 47.3 years; by 2005, life expectancy had increased to 77.8 years of age.

Reasons for Declines in U.S. Mortality Rates

The decline in U.S. mortality rates during the first half of the 20th century is largely attributed to declines in infectious disease. Public health efforts and medical advances, including vaccines and antibiotics, helped reduce the infectious disease rate. In 1917, vaccines for cholera and typhoid were introduced, followed by additional life-saving vaccines protecting against diphtheria, tetanus, tuberculosis, yellow fever, polio, measles, and influenza.

Improvements in water quality in U.S. cities between 1900 and 1940 also had significant favorable effects on reducing U.S. mortality rates. Chlorination and water filtration in U.S. cities helped to instigate a decline in death rates in urban areas during this period. Clean water had an even larger impact when considering infant and child mortality rates in the United States during the first half of the 20th century. Antibiotics, or antimicrobial agents that deter disease-causing bacteria, also had an impact on mortality rates at this time, with penicillin, discovered in 1928, credited as the first effective antibiotic.

Mid-Century Shift From Infectious to Chronic Disease

By the mid-20th century, a dramatic shift in causes of mortality was underway as a rise in chronic diseases associated with an aging population became dominant. NCHS data reveal that the five leading causes of death in 1900 include

influenza/pneumonia, tuberculosis, diarrhea, heart disease, and stroke, a significant change compared with 2005 when heart disease, cancer, cerebrovascular diseases, lower respiratory diseases, and accidents are the leading causes of death (see Figures 2 and 3).

While mid-20th century data appear to be similar to the present, some differences are notable. Tuberculosis was the seventh leading cause of death in 1950; it is no longer in the top 10 in 2005. In contrast, Alzheimer's disease is the sixth leading cause of death in 2005. Age-adjusted death rates

reveal that mortality due to heart disease and cancer has declined. Lifestyle factors have received increasing public attention as public health campaigns focus on exercise, diet, alcohol consumption, smoking, sleep, obesity rates, and stress levels as targets to improve health and decrease mortality.

While the 20th-century improvements in age-adjusted mortality rates are noteworthy, significant variations remain. Exposure to environmental factors, such as pollution and temperature extremes, are implicated in higher death rates. Further, improvement in health status and declines in mortality rates have not been evenly realized across all sectors of the U.S. population; notable gaps based on age, race, ethnicity, socioeconomic status, and gender remain.

Factors Influencing Mortality Rates

Socioeconomic Status

Mortality rates are often linked to socioeconomic status as people with higher levels of income, education, and occupational status have a greater life expectancy. Cross-national research reveals that the highest average life expectancy is found in countries where income variations between poor and rich are the smallest; health inequalities that intersect with mortality rates are thought to stem from what has been called the amount of relative deprivation in each country.

Sex Differences

Sex differences in U.S. mortality rates have long been documented. Explanations include exposure and response to stress, changes in health care, and lifestyle factors. While male mortality rates have typically been higher than female rates through the 20th century, during earlier times, the risks associated with pregnancy and labor made women during their childbearing years particularly vulnerable. Differences in mortality between men and women remain; one such difference lies in the gender gap in life expectancy, which in 2005 was 5.2 years.

Racial/Ethnic Differences

Differences in U.S. race and ethnic mortality rates have been particularly persistent over time. Comparing the African American population to Caucasians in 2005, life expectancy for the Caucasian population was 5.1 years longer. These same differences are noted for maternal and infant mortality rates. The maternal mortality rate for the African American population in the United States is 3.3 times greater, and the infant mortality rate is 2.4 times greater. The overall maternal mortality rate in 2005 was approximately 15.1 deaths per 100,000 live births, with the rate for African American women at 36.5 deaths per 100,000 live births, compared with 11.1 deaths for Caucasian women.

Conclusion

During colonial times and through the end of the 19th century, U.S. mortality rates were largely linked to major health threats involving infectious disease often associated with poor hygiene, sanitation, nutrition, weakened maternal or infant health, and physical injury. Chronic diseases like heart disease and cancer have played a much larger role in U.S. mortality rates from the mid-20th century through the present.

There remains ample opportunities for improvements in U.S. mortality rates. The future of U.S. mortality rates is contested, as many scientists believe that the declines realized over the 20th century will slow due to biological limits. Yet others suggest that scientific breakthroughs may lead to future reductions. Census Bureau projections suggest that U.S. life expectancy at birth will continue to increase with the most optimistic estimates predicting life expectancy in 2100 to be about 94 years.

Mortuary Rites

Rites or rituals as described by some authors are common features in all human societies. They consist of gestures and words dedicated to an object, such as a person, group of people, an occasion, or a material thing, of which the sacred character is acknowledged in a given human community. This kind of behavior should be distinguished from mere perfunctory conduct, as prescribed by codes, for instance. Rituals are met at all levels of the social order, within small arenas as well as society at large. For most sociologists and anthropologists, the function of rituals is to secure a certain mastery of temporality: The same gestures, words, or songs give the impression that time always goes through the same common places. This is the collective way of responding to the need for "ontological security," as defined by Anthony Giddens.

The occasion of death is of course one of the main anchorages of ritual behavior, be it for an individual, a small collection of people, or a vast gathering of people. This behavior is related to two outstanding social duties toward both the deceased and the bereaved. There is first the duty of saying farewell to the dead, and second, the duty of welcoming the dead in the realm of the dead. In a much-celebrated work, Arnold van Gennep sketched the general outlines of all "rites of passage," valid in principle for all kinds of human societies. Resorting to various stage sequences, the aim is to bestow upon an individual or sometimes a collection of individuals a new identity leading to a new condition. This is true of all the great events in one's life, like birth, initiation, marriage, enthronement, and death. Those rites follow a tripartite pattern: A first sequence underlines the separation of the individual from his or her group of belonging; a second one aims at placing him or her at the margin, figuring in this manner his or her transitory status; and a final one integrates the individual into a new status. Of course, this pattern is subject to many variations according to the huge display of cultural contexts within the human order of things.

In a seminal chapter of his famous book *The Elementary Forms of the Religious Life,* Emile Durkheim makes use of the words "piaculary rites," indicating that the origin of these rites lies in the idea of expiation. But the meaning of the term is broader: "Any misfortune, anything that is of bad omen, anything inspiring feelings of anguish or of dread calls necessarily for a *piaculum,* and, by consequence, is called *piacular.*" Therefore, bereavement represents one example of piacular rites. Durkheim then distinguishes between rites of pure abstention and rites of ceremony, the first pertaining to his notion of negative cult and the second, positive cult. Abstention, for example, means it is forbidden to mention the dead person's name, to stay at the place where the death occurred, or to deal with foreigners. The reason for such prohibitions lies in the sacred character of the dead, that is, his or her body. All that is or has been related to it finds itself, by contagion, in a religious state that excludes any contact with the things of the secular realm.

The positive cult rendered to the dead schematically follows a three-stage pattern (in the actual or virtual presence of the corpse), possibly completed by a fourth stage, sometimes long after the funeral. These three stages are (1) a farewell of the living to the dead, (2) the translation of the corpse from the realm of the living to that of the dead, (3) the reception of the dead person in the realm of the dead followed by the disposal of the corpse, according to the cultural habits of a

particular community. Often these rites begin with the moment that the death seems imminent. All stages include prayers and tears, sometimes also dances and songs, or at least some kind of music. Speeches are also held, often in praise of the deceased. Praising, even by concealing possible misdeeds, is the rule, and the fact is that most of the members of the audience are not duped.

The Three or Four Stages of Mortuary Rites

The first stage, following van Gennep's pattern, is that of the farewell to the deceased by the realm of the living. The assembly announces to the dead person that he or she is no longer a member of the community: Most of the time, the announcement is made by a prominent or specialized member of the assembly. In religious settings, this duty rests upon the shoulders of a member of the clergy. The ceremony over which he or she presides has a liturgical character. Even when it takes place within a secular environment, as with cremation in the absence of a churchman, it tends to inspire religious pageantry. In the Catholic world, the ceremony used to be the occasion of playing a *Requiem*. The deceased is called to rest eternally in the church's womb. It can be said that this stage is generally the most dramatic of all that take place in the presence of the dead body.

The possible fourth stage, that of the commemoration, may sometimes bear the same dramatic character, especially when the deceased has not been allowed to leave the community with enough dignity. Then the act of commemoration is akin to one of repentance, or at least of rehabilitation.

Usually, the rites of translation are to be seen in the habit of funeral corteges, which in ancient times displayed many mourners and much public grief. Sometimes this grief was feigned by people paid for the occasion, hired from the poorer part of the population. In some countries, weeping female mourners would also be hired, and they would let loose their tears at every stage of the ritual process. In the contemporary experience, the motorized hearse drives at normal traffic speed from the funeral parlor, the hospital morgue, or, more rarely, the home of the deceased to the church, or directly to the cemetery or the crematorium, followed by a small number of cars. There is practically no sign of mourning. The presence of wreaths on the hearse is the sole token of the "last journey" of a previous member of the living society.

The next stage is that of the welcoming into the realm of the dead. This may take place at the side of the newly dug grave, in the form of prayers and/or a brief speech by the officiating minister. The same can be said of cremation ceremonies. But in some societies, much rejoicing may occur, taking the form of festive meals and other kinds of celebration. Animal or even human victims are sometimes slain on the grave or on the pyre. In India, the widowed wife would self-immolate on the burning body of her late husband. All these rites have the same meaning (i.e., of emphasizing the definitive departure of the dead and the starting point of the bereavement period for the survivors). The latter are often compelled to wear clothes or other signs indicating their state of mourning. In modern Western society, these signs have nearly, or sometimes completely, disappeared.

It may happen that the treatment of the corpse is delayed with regard to the welcoming ceremony, which may also include farewell words or gestures. The scattering of the ashes, for instance, may take place after a certain lapse of time after the cremation itself. Or the actual burial may be postponed with regard to the farewell ceremony, and be held in an exclusively private way. In traditional Jewish culture, a special ceremony, that of the inauguration of the grave (i.e., the placing of the gravestone) takes place at the first anniversary of the death.

Durkheim has rightly stated that what lies at the origin of the mourning behavior is "the impression of weakening which is experienced by the group when losing one of its members. But this impression in itself results in bringing closer the individual members, connecting them more narrowly, and associating them in the same soul spirit, from which emerges a feeling of comfort compensating for the initial weakening." Grief behaviors are supposed to reaffirm the existence and the cohesion of the group, in some cases of the whole community, when one of its prominent members has passed away, or when a highly symbolic death has occurred (e.g., that of a child or a victim of a horrendous crime). In many cases, these behaviors are to be performed for a longer time within the directly related group of the dead, such as relatives and close friends, than within the society at large.

Wearing mourning clothes, weeping at any evocation of the dead, abstaining from washing oneself, or fasting, are typical forms of behavior, but many other forms are found all over the world. Also ranked among the piaculary rituals are the habits of inserting obituaries in the newspapers, placating them in public venues, the sending of letters of condolences, and also the holding of religious services at regular intervals after the deceased's departure.

Commemorations and Remembrances

Commemorating means reviving the memory of some important event. Examples are numerous at the collective level: birth of a Nation (4th of July), death of the Ancient Regime (14th of July), and explosion of a revolution (7th of November), and so forth. Some of these collective revivals deal with death, be it that of a lone individual (Gandhi or Martin Luther King) or that of a huge number of individuals, such as at war (Armistice Day as celebrated at the Cenotaph in London on the nearest Sunday to November 11). With the popularizing of the "duty of memory," commemoration ceremonies have become rather common. Commemorating may also be staged at the individual or group level. The occasion may be that of celebrating a joyous event, as in the case of the silver, ruby, golden, or diamond wedding anniversary.

Commemorating one's death is in some contexts mandatory, in others not. The celebrating acts may be private, such as bringing flowers to someone's grave by way of a birthday present. The ritualistic dimension then becomes discreet and may even be unnoticeable: Saying a silent prayer on some occasions in honor of a deceased close relation is a kind of rite that remains secret, but its function is that of all rites, controlling the passing of time and seeing to it that oblivion does not occur.

Mortuary rituals seemed to be on the wane during the last few decades, but one can detect a kind of reversal of this trend, especially in cremation ceremonies. We can thoroughly get rid of someone's corpse, but never get rid of death itself. And trying to cope with it by resorting to rites remains one of the most imperious concerns of humankind, at all levels of collective existence.

Mortuary Science Education

Mortuary science education is designed to train individuals to become funeral directors and embalmers and assist them to meet state-imposed licensing requirements. Postsecondary mortuary science programs are most prominent in the United States and Canada. This is due, in part, to the high rates of embalming in these two countries, combined with governmental licensing requirements for funeral practitioners. Internationally, most training of funeral workers is done through apprenticeships. Japan, for instance, which adopted a national examination for funeral workers in the 1990s, has only two schools with programs in funeral direction. In the United Kingdom, formalized mortuary science education programs were instituted in 2008 (at the University of Chester and the University of Bath). In Australia, there are no educational requirements for funeral workers, though there are six programs that award nationally recognized certificates. Similarly, New Zealand has one university that offers two separate degrees for funeral work but does not require its funeral workers to hold a degree.

Although most countries lack formal education requirements for funeral workers, many national trade associations are attempting to introduce legislation to mandate educational prerequisites in

their respective countries. The International Federation of Thanatologists Associations (IFTA), founded in 1970 and headquartered in Monaco and the Netherlands, includes Canada and the United States as members. One of the objectives of the IFTA is to advocate for global educational and regulatory standards for funeral workers that are uniformly administered.

Most funeral workers in the United States and Canada are required by law to be licensed to practice their trades. However, only some funeral workers are required to have formal education, a requirement that varies from state to state or province to province. In the United States, where workers must have at least some postsecondary education, the American Board of Funeral Service Education (ABFSE) is responsible for overseeing mortuary science and funeral directing education programs. The International Conference of Funeral Service Examining Boards (ICFSEB) oversees the tests that are administered to students wishing to become licensed practitioners, and a liaison works between the ABFSE and the ICFSEB to ensure continuity of criteria.

While the licensing of funeral directors is overseen by individual states in the United States, all people who desire to obtain a license must pass a national examination administered by the ICFSEB. Approximately half of all the United States and some Canadian provinces have a dual licensure program. In states and provinces that maintain two separate licenses, funeral direction and embalming are considered separate and distinct. Thus, there are different sets of requirements for obtaining each license. Almost all states and provinces, regardless of the licensure system, require some formal secondary education in order to be a licensed embalmer (often a 2-year associate degree). In places with dual licensures, funeral direction typically does not necessitate earning a college degree but an apprenticeship that, while varying in length, is generally one to two years.

Since 1970, the number of mortuary programs in the United States has increased from 21 programs to 56 accredited programs in 2005. There are currently 10 such programs in Canada, according to the Funeral Service Association of Canada. Slightly less than one-half of the U.S. schools make available some form of distance learning in their curricula. Most of these mortuary science programs are a part of 2-year, degree-granting institutions, but there are 4-year baccalaureate mortuary science programs in the United States. Some mortuary science programs offer additional certificates for those wanting to become pathology assistants and/or forensic investigators.

In 2008, members of the ABFSE narrowly voted against accrediting mortuary school programs that would allow students to earn a degree in funeral direction that excludes courses in embalming. The push for a degree in funeral direction only has been a recurring issue because of the funeral industry's trend toward the differentiation of occupational roles (i.e., workers specialize in embalming, sales, or funeral arrangements rather than all three).

History of Mortuary Science Education

Embalming, the central task around which mortuary education has evolved, is an ages-old practice that extends back at least to the ancient Egyptians. However, embalming in North America was most often used for the preservation of cadavers for the purposes of medical research. Prior to the American Civil War and for some time after, most Americans buried their dead close to home, either in church graveyards or in family burial grounds. Relatives and neighbors of the deceased took responsibility for cleaning and burying the body. The war dead often had to be transported hundreds of miles to their burial ground, creating a need to preserve the dead long enough to be returned home for funeralization.

Individuals known as embalming surgeons assumed responsibility for embalming thousands of the war dead, simultaneously exposing the public to a new aspect of funeralization. Additionally, following his assassination, Abraham Lincoln's body was embalmed. Tens of thousands of mourners viewed his body en route from Washington, D.C., to his resting place in Springfield, Illinois, providing further evidence for the utility of embalming.

The English translation of an 1838 text on embalming by the Frenchman Jean Gannal was another crucial turning point for embalming education. This work served as a canonical text for itinerant educators who traveled the countryside to train others in embalming techniques. It was only near the end of the 19th century when standalone mortuary colleges began to appear. The Cincinnati

College of Mortuary Science, founded in 1882, is the oldest such college in the United States.

The nascent funeral industry of the time provided two important cultural themes that continue to be evident in contemporary mortuary science education programming, namely (1) the importance of the apprentice relationship in the education of embalmers and (2) the putative association between embalming and the medical disciplines. Today, embalmers and funeral directors in almost every U.S. state and Canadian province are required to apprentice under the guidance of a licensed practitioner. Furthermore, where formal education is mandatory, coursework related to the health sciences are central.

Mortuary Science Curriculum

The curriculum of mortuary science education includes chemistry, microbiology, anatomy, and physiology, in addition to embalming and restoration. Social science classes, especially sociology and psychology, are also required in addition to more specialized courses in grief counseling. Today, curricula also include business courses, such as ethics, management, marketing, and law.

Presently, coursework in embalming and restoration remain foundational to mortuary science education. The learning of chemical and physiological components of death, as well as the tools and techniques used in embalming, are the majority of such classes. Students also learn the history of embalming, the ethical considerations involved, and the purposes behind embalming.

According to most practitioners, embalming has a threefold purpose. The first is to preserve the body by delaying decomposition and putrefaction. Students are taught about the effects of certain diseases or medications the deceased may have taken, either of which can alter the absorption of embalming fluids. Similarly, the length of time the body has been dead, the cause of death, and the physical environment in which the body had been in postmortem (and pre-embalming) affect the techniques of embalming and the selection of chemicals.

The second purpose of embalming has to do with sanitation. Embalmers legitimate their practice as a means to protect public health through the appropriate disposal of contagious tissues and the elimination of pathogens. Students receive instruction in the proper handling of bodies as well as embalming instruments. They are also instructed in the use of particular cleansers and disinfectants.

A final purpose of embalming is restoration of the body to an aesthetic and socially acceptable appearance. The need to do so seems more critical at a time when individuals experience longer lives. With the aid of ever-evolving medical technologies, people die at older ages and yet may have undergone trauma or extended periods of illness or suffering in the process. Thus, mortuary science students are educated on ways to create a visage that suggests an absence of suffering in the deceased.

This is accomplished through a variety of procedures. Dye is injected in order to provide color or, conversely, to mask discoloration of the skin caused by either illness or medication. Chemicals deodorize the body, the mouth is sutured shut, eyecaps are inserted, and specific tissues can be injected with fluids to plump them up or drained to reduce swollen appearances. Each technique is intended to provide funeral visitors with a final, pleasing image of the deceased.

Forms of Embalming

Two forms of embalming are taught: arterial and thoracic. Arterial embalming requires the use of an embalming machine to first drain the blood from the body. Next, embalming fluids are injected and the embalming machine circulates those fluids. One must learn to make an incision, raise the correct blood vessel, insert the equipment, and operate the embalming machine.

Thoracic, or abdominal embalming, involves inserting a hollow, cylindrical trocar into the stomach to aspirate the major organs of the chest and abdominal region before injecting embalming fluids into the body cavity, also with the trocar. Embalming bodies that have been previously autopsied or bodies that have missing tissues as a result of body tissue donation requires additional expertise.

Students enrolled in embalming courses are encouraged to also enroll in an internship program so that they may develop their learned skills. Some mortuary science programs also perform in-house embalmings for the surrounding community.

Restorative Arts

Mortuary science programs often distinguish between embalming and what is known as the "restorative arts." While the former involves the application and injection of chemicals for the preservation and overall appearance of bodies, restorative arts have to do with treatments and procedures to specific areas of the body. These more localized treatments are intended to address issues such as cosmetics application, the concealment of wounds, or the reconstruction of various forms of disfigurement that occurred around the time of death. Once referred to as demisurgery, the restorative arts emerged in the 1930s to repair bodies that had been heavily damaged or mutilated so that the loved ones might have an open-casket viewing and funeral service.

Typically working on dummies, students learn to fill in missing tissue and correct for disfigurements that can result from gunshot wounds, automobile accidents, or other violent bodily traumas. Students also learn about the application of cosmetics, airbrushing techniques, and the use of various tools with which to paint or spray on concealers. Students learn how to pack cavities, apply artificial facial and head hair, inject gels, as well as perform advanced stitching techniques. The molding of clays and wax-like putties to form physical features is another component in the restorative arts.

Trends in Mortuary Science Education

According to the ABFSE, the demographic makeup of students is changing. In 1971, approximately 95% were male, and men continued to make up the majority of mortuary school students to the beginning of the 2000s. By 2008, however, just over one-half of all enrollees in mortuary science programs were female. Furthermore, the average age of mortuary school students is increasing. Only one-fifth of new students are 20 years old or younger, while one-third of mortuary school students are over the age of 30. The typical student profile is changing in other ways as well. People of color also are enrolling in increasing numbers than ever before. The percentage of white students decreased from about 85% in 1971 to 63% in 2007. Black students make up about 25% of the current student population, and Hispanics enrollees make up about 8%.

Mummies of Ancient Egypt

The word mummy is derived from the Persian *mumeia,* referring to the bitumen material that covered the Egyptian corpse. Thousands of Egyptian mummies have been excavated, hundreds of thousands have been lost to mummy exportation and modern urban sprawl; perhaps millions more remain in the tombs and shifting sands of Egypt.

Mummies have been part of popular culture throughout the past millennium. The European mummy trade was active for centuries, and much of this interest in mummies increased as a result of Napoleon's Nile military campaign of 1799 when a French soldier found the Rosetta stone. This stone had three sections of writing, Greek and two forms of old Egyptian writing, namely demotic script and hieroglyphics. In 1823, linguist Jean-François Champollion cracked the demotic and hieroglyphic code, which was based on a language related to Coptic.

From the Middle Ages onward, Europeans were fascinated with mummies. Placed on public display throughout Europe from the 1400s through the

1700s, mummies were thought to have medicinal benefits. Thus, human bones were ground into powder intended to serve as a cure for migraines, stomach ulcers, paralysis, and poisoning. Mummies also were used by farmers as fertilizer. Artistic paint mixed with mummy powder was used to create colors thought to have a longer lasting effect. In the 1800s, in Canada, the linen used to wrap mummies was imported to make paper, but this practice ended because of the fear of disease. And, even in Egypt, mummies were burned to fuel trains. Today, Egyptian mummies remain popular attractions for a variety of venues, including horror movies and museum exhibits.

Much of what is known about ancient Egypt is centered on Egyptian beliefs of death. Within this cultural orientation it was believed that an individual continued to exist; that is, the dead would be reborn. All that they possessed and all that made them what they were in this life remained when they were reborn. Based on this belief, many ancient Egyptians spent their entire life preparing for death. Wealthy individuals also believed this transition should be celebrated.

The ancient Egyptian death ritual progressed in an orchestrated manner after death, with mourning, preparation of the corpse, interment, and rituals for the deceased that would be continued in perpetuity. Mourning the deceased lasted up to 70 days. Believed to be useful in assisting the living to cope with death, ceremonies such as the "opening of the mouth" were thought to reanimate the dead organs and senses, particularly affecting the deceased's future ability to speak. Thus, the mummy and a statue of the deceased would be touched by a priest near the mouth using tools such as an adze and a forked *pesesh-kef* knife. This allowed the corpse to speak words that would enable the individual to continue on the path to the afterlife. Families also spoke with and brought food to the corpse, while also performing rituals during the mourning period.

Believing in the afterlife, Egyptians kept the corpse intact through mummification. The pre-Dynastic Egyptians noticed dried bodies were preserved by hot, dry sand, and were not destroyed by maggots that would normally thrive on decaying tissue. During the Early Dynastic period (3150–2686 B.C.E.) attempts were made to stop the postmortem putrefaction by wrapping corpses in linen. During this period (2686–2181 B.C.E.), Egyptians practiced a technique that allowed better body preservation through the removal of the internal organs, which were then independently preserved.

Egyptians performed embalming and employed it on the wealthy and the poor. And, because all living things were believed to be reborn and this rebirth was thought to be a continuation of individual existence, animals were mummified as well. The most elaborate mummification techniques appear to have been employed during the New Kingdom dynasties (1570–1070 B.C.E.) and the final dynasties of the pharaohs. First, the brain was scrambled and extracted through the nostril by a hook that was jabbed into the cranial cavity. An incision was made on the left side of the body to remove the lungs, stomach, liver, and intestines, and each was placed in a canopic jar sealed by a figural head of one of the Four Sons of Horus, deities that guarded specific organs into the afterlife: Imseti (a human—liver), Hapi (a baboon—lungs), Qebehsenuef (a falcon—intestines), and Duamutef (a jackal—stomach). The heart muscle, believed to be the site of intelligence, was never removed. The incision would be covered with wax or an amulet bearing the eye of Horus. The body was then cleansed with palm wine and pounded spices such as myrrh. Even the eyes were removed and replaced with wax or resin, stone, or even onions. With the organs displaced, the body cavity was filled and the body was covered with a natural salt or natron and left to dry for 40 to 70 days.

Embalmers attempted to make the dried corpse look lifelike by filling parts with sawdust, plumping up the cheeks of the face and padding the genitalia. Often animal fat and plants were used to preserve and soften the body, which was also coated with beeswax and exotic resins. Linen would be used to wrap the corpse.

The wealthy would have each toe wrapped individually and may have each toe housed in a sheath of gold. A mask was then placed over the mummy's head and the mummy was ready for burial. The poor were covered in natron, and oil of cedar or other solution was injected in the anus. Once liquefied, the intestines were purged when the anus was unstopped.

The Golden Age of Egyptian archaeological discovery was the period between the two World Wars when a most dramatic archaeological find

resulted in the discovery of the undisturbed tomb of the Pharaoh Tutankhamen on November 26, 1922. Tutankhamen was a minor ruler who died at the age of 19, probably due to an accidental fracture in the leg that became gangrenous. His burial tomb with its striking gold death mask, gold and jewelry, an enormous amount of art and wooden crafts, ritual figures, funerary furniture, clothing and textiles, games, musical instruments, and chariots among many items made Tutankhamen the most famous mummy of all time.

Within physical anthropology, paleopathology was to gain much notoriety as a scientific discipline as a result of the physical examination of mummies. Three individuals began the macroscopic mummy investigation: Grafton Elliot Smith, a neuroanatomist who is alleged to have dissected 30,000 mummies without a detailed record existing; Warren Dawson, an insurance man who became a self-taught anthropologist interested in mummification; and Alfred Lucas, a chemist who focused on the natron and other substances found on and in mummies. Sir Marc Armand Ruffer (1859–1917) would take paleopathology and mummy studies to the next level, and he would start the true scientific research on mummies. Sir Ruffer believed that with every excavated mummy, the potential knowledge gained for medical science was significant, and he explored well beyond the macroscopic examination to microscopic evaluation of the mummy tissue. He figured out how to rehydrate the soft tissue of mummies and made histological slides in order to examine the tissue for diseases. Through histological analysis, Ruffer found the calcified eggs of the blood fluke *Schistosoma* in the tubules of the kidneys of mummies dating before Christ. Not only was Ruffer one of the first to use x-rays in the analysis of mummies, but he also realized the epidemiological importance of the information to be recovered from mummies. His publications on mummies included entries on malaria, congenital conditions, tuberculosis, arthritis, and atherosclerosis. An edited volume of Ruffer's work was published after his untimely death in 1917.

The scientific study of mummies slowed during the next 50 years as physical anthropologists perfected their methods of analysis and medical technology slowly became more advanced. In the 1960s, medical doctors and physical anthropologists again turned their interest to mummy studies, and that interest continues to the present. Improved radiological equipment, new medical instruments, and the use of CT scanners have brought to bear new findings without damaging the mummy by unwrapping the linen. Scans allowed scientists to determine that the brain was removed, resin material and packing material was placed in the body cavities, and that a corpse might have congenital skeletal abnormalities, familial skeletal and dental traits, pathology, or inflicted trauma. CT scans have been pieced together to provide Internet explorers with a virtual tour through the chest cavity of a mummy.

Diseases such as leprosy and tuberculosis have been diagnosed in the remains of mummies and the DNA from *Mycobacterium tuberculosis* has been extracted. Electron microscope analysis of liver tissue has indicated the presence of liver flukes, and lung tissue examination has yielded particles that indicated that the body of Nekht-Ankh had a sand pneumoconiosis. X-rays have shown nodules in the abdominal wall of mummies, which reveal remains of Guinea worms. Hydatid cysts caused by the dog tapeworm have been found in mummies by the use of an endoscope. Histological examination of muscle tissue of mummies has resulted in the isolation of parasitic infestations. Hair has been examined to help determine ethnicity. Immunohistochemical staining of tissue has advanced in such a manner that the identification of tumors and antibodies to certain cancers are noticeable in mummies.

Mummies of ancient Egypt have become symbols and an identity. This nationalism/mummy nationalism is largely due to the efforts of the Secretary General of the Supreme Council of Antiquities in Egypt, whose mission has been to publicize each new discovery, such as the recent identification of the mummy of Queen Hatshepsut, and to preserve the national monuments, mummies, and treasures. Museums that have mummies and artifacts from Egypt are being contacted and asked to return looted and confiscated items back to Egypt. These efforts resulted, for example, in the return to Egypt of the Ramesses I mummy in 2003 from the United States after having been on display for many years in a Niagara Falls, New York, museum and later in Atlanta, Georgia.

Mummification, Contemporary

Principally, the process of mummification involves the desiccation of the body, thus differing from embalming, which substitutes bodily fluids for substances that slow down the process of decomposition. The ancient Egyptians perfected their technique over many hundreds of years. In the beginning, they struggled to achieve the same results that could be found within naturally desiccated bodies buried within the hot, dry desert sands. Their practice developed alongside religious and royal ideology, with the first individuals to be deliberately mummified being the Pharaohs of ancient Egypt in around 3400 B.C.E. The desire to achieve immortality through the preservation of the body became a practice that was extended down through the royal family, the nobility, and eventually the rest of the population. The treatment that was afforded the poor was of much lower quality than that given to the wealthy.

Contemporary Mummification

Today, a range of different methods are available concerning how the body is to be treated after death. However, the Church of Summum, based in Utah, prides itself on being the only organization to offer mummification as part of the funerary rites. It was publicly founded by Summum Bonem Amen Ra (formerly Claude Nowell) in 1975, taking inspiration from ancient Egyptian religious practices.

The term that Summum applies to their modern mummification procedure is "thanatogenetics." Although this mummification has been adapted from the original concepts of ancient Egyptian practices, their techniques for preserving the body have been extensively researched. Ra spent years perfecting the method with colleagues and students at the Lynn University, Boca Raton, Florida, using over 30 human and 40 animal cadavers to find the best way to preserve remains. The actual tools and formula used are a heavily guarded secret, despite the amount of media attention that the organization has received. At the end of the treatment, the body is wrapped in multiple layers of gauze and cast in "mummiform" fiberglass. The entire process is intended to ensure that putrefaction does not occur and the genetic structure of the body remains "at an optimum," which would in theory allow for DNA retrieval and perhaps the cloning of the deceased in the future.

The Church of Summum is a nonprofit organization, and costs for mummifying a family member or pet vary, with the money going toward the costs of materials used in the process. According to their website, this is a service that appeals to a variety of different people, ranging from those who feel drawn to elements of ancient belief systems to those who seek comfort in knowing that they will be preserved (and possibly remembered) for years to come. For many, inhumation and cremation are not desirable modes of burial, and therefore mummification may be the answer. The services proffered by Summum do not end with the mummification of the body. A special mausoleum "museum" is on offer to clients so that their bodies can be viewed and appreciated by family members, encouraging more of a relaxed and "at ease" view of death.

Even though the Church of Summum is fundamentally attempting to continue an ancient process, the fact remains that knowledge of many of the techniques employed by the ancient Egyptians are still lacking in detail. To learn more, a variety of different sources need to be studied—including the remains of the ancient Egyptians themselves. However, these bodies are precious and are embroiled in ethical

debates concerning their study and display. As a result, Egyptologists and scientists have had to seek alternate means to test their hypotheses.

In 1993, Bob Brier and Robert Wade, in conjunction with the Maryland School of Medicine, created a mummy based upon ancient Egyptian tools and techniques (including some 400 pounds of dry natron) applied to a modern human cadaver. The goal was to make a human mummy that would both macro- and microscopically stand the test of time. There are acknowledged difficulties in obtaining ancient DNA from Egyptian mummies, which would allow the study of genealogies, owing to problems such as degradation and contamination. Brier's experiment is thus a useful resource for the study of the impact of mummification upon molecular structures in the body.

Natural Mummification and Preservation

Contemporary mummification is not always deliberate, nor is it always desiccation that leads to a body's preservation. There are a number of natural ways in which a body may survive in an exceptional state of preservation without deliberate intervention. Furthermore, these relatively modern—often beautifully preserved—mummies can be found all over the world. Many act as testimonials to a religious way of life, ranging from the self-mummified bodies of Japanese Sokushinbutsu to the air-dried Capuchin monks of the Palmero catacombs, Italy. Others are the sometimes strange or tragic byproducts of the environment, providing an opportunity to see a snapshot of someone's last moments prior to death, such as the frozen corpses of members of the Franklin Expedition (1845–1859).

Finally, it would appear that "contemporary" mummification has different connotations to the "ancient" variety. The ancient Egyptians developed their techniques as a response to their religious beliefs and the environment in which they lived. Today, the reasons and methods behind mummification are as diverse at the people found in this state. Regardless, they all command respect and awe and have the ability to communicate something about themselves and the way in which they lived, even in death.

Museums of Death

Museums are institutions that collect and display objects or artifacts of scientific, historic, cultural, or artistic value. Museums of death focus almost entirely on issues surrounding death, funerals, and memorialization in Western society, and on the objects produced as part of the mourning and memorialization processes. Since the 19th century, Europe, America, and many other countries have developed commercial enterprises surrounding funerals and mourning, while other societies and cultures have held onto traditional rituals of burial and memorialization. This entry describes collections that feature the wide range of death-related objects in different cultures and time periods in specialized museums of death.

Most museums of death are relatively new, having been founded within the past few decades. The reasons that this type of museum is now found to be more culturally acceptable are complex, but there are several factors to their growing popularity. Those factors include the deterioration of long-standing, primarily 20th-century taboos about public discussion of death and dying and the public displays of corpses, and an increased interest in the history of the rituals of burial and mourning.

An interesting point is that most of these museums do not explicitly call themselves "museums of death," rather they choose names that nevertheless reflect their related focus, for example The Museum of Funeral Customs in Springfield, Illinois; The Museum of Mourning Art in Drexel, Pennsylvania; or The Funeral Museum in Vienna, Austria. Museumgoers clearly understand what kinds of exhibits they will see, and that these will be related to death and dying in some way. Some museums take a kitsch, pop-culture approach, using humor as part of their message—for example, the motto of The National Museum of Funeral History in Houston, Texas is "Any day above ground is a good one." In general, however, these museums do not attempt to glamorize, romanticize, or glorify death, as often happens in films, rather their focus is on presenting objects and information in a historically accurate and culturally interesting way to foster discussion about how modern societies have dealt with death, dying, and mourning.

Caskets

Typically, the most prominent display for any funeral museum is the collection of coffins and caskets. In America, until the 19th century, coffins were usually made by a local carpenter or cabinetmaker who made up a simple wooden box on demand. Later, as the preparation and display of the deceased was increasingly taken over from the family by commercially run funeral parlors, the coffin business also specialized. "Caskets," or fancy coffins, became popular through clever marketing; these take their name from Renaissance jewelry boxes—an appealing name to the bereaved, evoking the thought of treating their beloved as they would a "precious gem." Caskets often feature luxurious interior fabrics (e.g., silk), and ornamental hardware—handles and name plates—of brass, gold, or silver. Catalogs for this hardware dating from the 19th century are veritable treasure troves of 19th century design. Some museums, for example The National Museum of Funeral History (Houston, Texas), also display innovative coffins or oddities, for example the "cooling" coffin that, in the days before refrigeration, allowed for the inclusion of ice to help delay putrefaction. Other things related to funeral culture and burial, such as shrouds, are often also included in funeral museum exhibits.

Of European museums of death and funeral culture, the Vienna Funeral Museum is probably the best known. Founded as an extension of the Viennese Municipal Funeral Department, the museum presents the history of Austrian, and specifically Viennese, burial and funeral history through the department's own collections and business papers, including coffins and hearses. However, museums specializing in funerary art, history, and culture can be found all over Europe, including in major cities, such as London, England; Paris, France; Amsterdam, the Netherlands; Budapest, Hungary; and Hamburg, Germany. The Museum for Sepulchral Culture in Kassel, Germany, specializes in the history of monuments.

Funeral Vehicles

Hearses, or conveyances to transport the dead, form another major component of many funeral museums. Before the 19th century, coffins were either carried by mourners to the graveyard or taken by horse and cart, a utilitarian mode of transport that was used for many different purposes on a daily basis. The development of a specialized vehicle to transport coffins and caskets dates from the 19th century; these vehicles were often splendidly outfitted, with sumptuous and plush interior upholstery, draperies, tassels, and exterior decorations. The more important the dead, the fancier the hearse used—sometimes including pairs of color-matched horses with large plume headdresses and ornate harnesses. Since the advent of the automobile, hearses are now usually black cars, with some vestiges of 19th century black drapery. Occasionally, museums display unusual hearses, for example the Mercedes hearse that transported Princess Caroline of Monaco at her funeral. The Museu de Carrosses Funebres (Museum of Funeral Hearses) in Barcelona, Spain, has in its collection hearses dating from the 18th to the mid-20th centuries, and includes ornate baroque horse-drawn carriages, as well as a silver Buick, and white carriages that were used for children and virgins.

Embalming

Another compelling subject for such museums is the topic of embalming. Embalming has been

practiced in one form or another since ancient times—Ancient Egypt is the best known, but other civilizations including the Incas and ancient Chinese also used it as part of preservation and mummification techniques. While embalming largely fell out of favor for centuries in Europe, in America techniques for efficient and sanitary embalming were developed, particularly during the American Civil War (1861–1865), when family members seeking the return of their war dead helped to popularize the practice. Museums often display different types of embalming techniques and products through the years, and the advances in embalming equipment that have been developed.

Mourning Collections

Some museums specialize in collecting and displaying the large variety of objects that are related to mourning and remembrance. In early America, tokens, such as gloves or rings, were given out during funerals to eminent attendees; these are now found in some museum collections. George Washington's death in 1799 was the first to generate widespread public mourning in America. For years after, artifacts were commercially produced to commemorate Washington's death, including lithographs, handkerchiefs, and ceramics showing images of mourners at Washington's gravesite. Young schoolgirls were taught to paint or embroider fancy pictures commemorating the deceased members of their families; these became treasured heirlooms. These objects, whether commercially produced or personally crafted, tell of the history of mourning.

The 19th century witnessed the development of elaborate rituals and objects of mourning in Western European and American history, wherein Queen Victoria was extremely influential. Upon the death of Prince Albert in 1861, the Queen embarked on a prolonged period of private mourning that lasted until her own death in 1901. Queen Victoria's private grief and her public role as the longest reigning monarch in English history helped to promote the development of an array of artifacts to publicly express one's status as a mourner and to preserve the memory of the deceased. Widows were expected to adhere to a rigid series of stages in their dress, behavior, and interactions with the outside world for up to several years. Color was the primary indicator of the degree of mourning. During the early "full" or "deep" mourning period, women wore either all black or all white. Men were also expected to wear dark clothes, but for shorter periods. Later stages of mourning allowed for a gradual return to color, first gray, then in the final stage, purple or violet. Accessories such as gloves, hats, fans, and handkerchiefs conformed to these colors. Specialized stores and department stores were important purveyors of mourning goods, including the black-bordered stationery (with different-sized borders, depending on the mourning stage) used during the mourning period. Crape, a type of fabric, was especially associated with mourning clothes, and was also used to drape front doors or buildings to signify public or national mourning, such as in the period following the assassination of President Lincoln in 1865. All of these types of objects—clothes, accessories, fabric, and stationery—are often exhibited by museums interested in the history of death and dying.

Yet another significant category of museum death-related collections is mourning jewelry. From the late 18th century onward, mourning rings, brooches, cameos, bracelets, necklaces, and pendants appear in great and elaborate varieties—some with images of urns (a classical motif referring to the ashes of the deceased), some containing hair of the deceased, often with small pearls, and others made simply of black jet, a stone made popular by Queen Victoria.

Postmortem Photography

Technological developments also spurred the growth of another mourning-related industry, the postmortem photograph. After the introduction of photography in 1839, photography studios soon flourished in many towns and cities across America. One specific service of the photographer was to visit the home of the bereaved to take a photograph of the deceased, either posed in some way to appear alive (or if an infant, in the mother's arms), or lying in the casket. A postmortem photograph allowed a mourner to retain a visual representation of the deceased. Although this practice was fairly common in 19th-century America (less so in Great Britain), these photographs today are relatively rare and often make their way into museum exhibits as

oddities. Postmortem photography is still used today, particularly as a therapeutic tool for parents who have lost a baby or a young child; these images may one day form future museum exhibits.

Ephemera

Other types of mourning artifacts were of a more ephemeral nature—that is, they were not necessarily meant to be useful beyond the period of mourning, although sometimes these objects survived anyway, saved by family members and friends. Such artifacts include the memorial cards handed out at the funeral. These cards, usually black (or white, for children and occasionally women) with gilt-edging and gold print, were bulk printed, and contained the name of the deceased, birth and death dates, and usually a standard verse or poem. Some artifacts were disseminated in great numbers during the mourning for a national figure, for example black-edged ribbons and memorial cards for President Lincoln. Today, funeral programs and cards from the mid- and late 20th century are of considerable interest to museum curators, since objects like these form part of the continuum of the history of mourning and funeral practices.

Conclusion

Museums that deal with death-related topics and artifacts don't just collect ancient "relics" or antique objects, or focus on Europe and America. Contemporary objects such as 19th- and 20th-century funeral home items—for example, fans or calendars distributed by the business, funeral programs, or monument catalogs from various companies—are also of interest to historians and museumgoers. Additionally, foreign or exotic civilizations and cultures are often well represented in large, general audience, natural history museums, with inclusion of their death and burial-related artifacts. Museums about death, dying, and funerals thus present varied aspects and culturally different ways of memorializing death, dying, and bereavement throughout history.

Muslim Beliefs and Traditions

In Islam, spiritual belief refers to the existence of God and the total belief in the One and only God, Allah, and that Muhammad, the Prophet, is His messenger (*Kalimah Shahadah*). The basic fundamental beliefs of the Muslims, followers of Islam, are the true understanding of and total belief in the oneness of God (Allah). It is the first tenet in Islam. Everything that is done by a Muslim is directed to only one thing—to gain Allah's pleasure and blessings.

Muslims are guided by two major references, the Qur'an, the Islamic Scripture, and As-sunnah, the practice of the Prophet. For Muslims, the understanding of death, life, and the purpose of life derive from these sources. Every Muslim believes that there is life after death and, as stated in Islam's Six Pillars of Faith, life on earth is not as important as life in the hereafter.

The Purpose of the Creation of Human Beings

In Islam, to understand death, it is essential to discuss life, living, and its purpose. It is fundamentally

important to know, before death comes upon us, the purpose of man's creation. In fact, a Western view also agrees that loss through death must be experienced in order to understand the questions relating to life, death, and purpose.

In welcoming the newborn into a Muslim family, the *Azan* (ritual call to prayer) is said in the right ear of the child, and the *Iqamah* (ritual call to initiate congregational prayer) in the left ear. Those words are the first thing a Muslim child hears after coming into this world—the attestation of the belief and the call to worship the Creator. In Islam, life prepares a person to die. The Qur'an provides a complete guide as to how one should lead one's life. In life, one must submit oneself to Allah; one must learn to know and serve Allah. The Islamic concept of *Ibadah* (servitude) means that everything one does will result in getting a reward from Allah, provided that one does it in the cause of Allah.

Human beings have been placed at the highest rank of creation. We have been chosen to be God's vicegerent on earth and have been given the responsibilities, the duties, and the trust to ensure peace on earth. Above all, human beings are created with one ultimate purpose, to seek the pleasure of Allah. Therefore, how one leads one's life will determine how life after death will be for that person. Two important assumptions about life that affect one's death are accountability of behavior and life is a test.

Accountability of Behavior

All actions on earth determine one's place in the life hereafter. One is accountable for every single action and even the smallest events. In fact, happiness is mentioned twice in the Qur'an and both times refer to the life hereafter, not the life on earth. According to Sharif Muhammad, success is not measured by what we have in life. Instead, real success is one's ability to be saved from the punishment of hell and be admitted to paradise.

It is impressed upon all Muslims to be balanced in life so that life on earth is not abandoned in the hope for better life in the hereafter. Being balanced is about fulfilling the roles and responsibilities that one will be accountable for in the life hereafter. Besides the responsibility as a Muslim to submit to Allah, neglecting one's responsibilities to others, such as family, parents, neighbors, and employers, on earth may also result in later punishment.

Life Is a Test

The emphasis on life after death has made death a bridge or a transition from life on earth to the life hereafter. Life and death are created as a test to find who among us is the most righteous. Everyone will die, and this life on earth is just probation, during which one's faith will be tested by many things. Some are tested by calamities and some are tested by good things, but in the end all will return to Allah so that, based on merit, judgment is rendered.

As stated in the Qur'an, people shall be tested by fear, hunger, and loss, and Allah has created life and death with a purpose and a supreme wisdom. We are tested by both bad and good things, and life and death are created as tests. Allah only tests those who are capable of being tested, as He knows one's ability to handle the resulting stress. Muslims rejoice that Allah has promised that every test will end with relief. Islam explains death in full detail, how it happens, and what Muslims should do before, during, and after death.

Death in Islam: Important Concepts

1. Return to the Creator—Death is the time for man to return to the creator.
2. There is no escape from death—When the time comes for someone to die, it is impossible to escape from it.
3. Death is for everyone, regardless of age—Allah has not made a distinction between who dies first, the young or the old, the rich or the poor.
4. Time of death is unknown to us—No one has the slightest idea of when one is going to die.
5. All the actions stop after death—There is no turning back or bargaining for more time, as Allah has given us ample time to do our best deeds. Belated regrets or awareness are no good to anyone.
6. Death is not our final destination—Death is not the final destination in Islam. This is clearly stated in the tenets of Faith (*Iman*); all Muslim believe there is another life after death.

Life After Death: What Happens When a Person Dies?

Death is a day of judgment and a transition to the eternal world. A dead person will return to their origin. The physical or material aspect will return to earth buried in the grave; the spiritual aspect of man will return to its Creator, Allah. The *ruh* that was once breathed onto man will be lifted and returned to Allah, the Creator. It is a promise that every human has made to Allah upon his or her completion (as He breathed in His ruh in us) that one will return to Him, the Creator.

The Day of Judgment is the day when all deeds will be weighed. We make no defense, but must take responsibility for our behavior. Parts of the body, such as hands, legs, stomach, and eyes, will bear witness to one's sinful behavior. The good will go to heaven and the sinful will have to pay for their sins.

Role of Community: Relatives, Friends, and Neighbors

In Islam, care is extended to the family of the deceased by comforting the relatives, sharing their sorrow, and offering condolences, sympathy, and support. The necessary funeral preparation must take place immediately. Friends, relatives, and neighbors will help with the preparations, as the burial must be done almost immediately. In Malaysia, for example, a group of four or five trained individuals will be responsible for funeral preparation. They are not paid for this service to the community. But normally, the family of the deceased will give a token of appreciation in the form of money, clothing, or anything that the family can afford. Families, friends, and neighbors come to visit and offer condolences to the bereaved families.

Coping With Death

Every true Muslim has been exposed to the basic understanding of death. It is the understanding and belief in the concept of Divine Will (*Al Qada* and *Qadar*) that affect one's acceptance of death. This knowledge, in the first place, helps a person cope with loss when death occurs. Muslims are asked to prepare for their own death because one's life and death are in the hands of Allah and no one knows the exact time of their death.

Although life after death (*Alam Barzakh*) is an invisible phenomenon and hence inconceivable by worldly means, Muslims are encouraged to contemplate death through God's creations. As Muslims contemplate the lives of human beings in the darkness of the embryonic stage and compare it with life after birth as one grows into adulthood, then by extension, one can visualize the vastness of what one will experience after one is freed by death.

We can observe the influence of the important elements of the Muslim religious belief system and its acceptance of death as divine will as reported in the research finding of how death is dealt in a Malay community. A study of a close family member's death among Malay Muslims conducted in 2005 to 2006 reveals three types of responses toward death: (1) universal response, (2) religious spiritually inclined response, and (3) Malay ethnic-cultural responses. Universal coping responses include shock, denial, and the rejection of the news of death. Religious spiritually inclined responses are praying and making *doa* (supplication) as well as reciting Qur'anic verses, *Yaseen*. Not long after the initial reaction of disbelief, many Muslim Malays turn to religious teaching as a coping mechanism. Malay ethnic-cultural responses include visiting the grave on specific occasions, a symbolic initiative important to the living, and holding small gathering or feast for relatives and close friends for 3 or 7 consecutive days, followed by the 40th day and 100th day. This study clearly demonstrates that the remembering of death is a significant coping mechanism for Muslims regardless of how one reacts initially to the news of the death of a loved one. For Muslims, the knowledge of the Islamic view of death, a view that death is in the hands of Allah, serves an important means through which they can face death, cope with and deal with social and personal life changes after death of a loved one, as well as prepare for the life hereafter. Hence, Muslim beliefs and knowledge help a Muslim be more prepared by doing things that will bring happiness to their life hereafter despite the fact they still have fear and anxiety to accept the "real" death.

Mythology

Mythology is a wide-ranging area of research that focuses on the development of individual identity, making the cosmos intelligible, social understanding as a collective experience, spirituality, the concept of birth and death, cultural awareness, and the relationships between these entities. It was in the 1920s that the ethnographic work of James Frazier and Joseph Campbell provided the foundational understanding of these elements and the current ideas in the field. From their work, current researchers in this area see death as a pivotal aspect, believing it to be the one unifying fear of all humanity that is expressed in narrative forms. This domain does not have a single definition of death, as the basic premise of myth is that individuals seek to understand their life-death connections as an individual emotional response. This is the case even when the individual subscribes to a collective religious belief system.

Hence, mythic response has lead to the development of a myriad of religious or spiritual beliefs, rites, and narratives. However, despite the variations, researchers in this discipline have recognized that because all of humanity are faced with death, similar themes emerge in the mythic narratives. The rituals, images, and language that describe and explain death over time and the cultural variations as well as the similar themes regarding these life-death relationships are the grist of mythic investigation with the core of understanding myths centering on three questions: Who am I? Where have I come from? and Where am I going? How individuals and groups answer these questions is related to their explanation of death within an interpretation of life.

In the death myths across the spectrum of current religious understanding, including Christianity's belief of entry into heaven after death, Buddhism's cycle of reincarnation, and Islam's rites of burial and entry into heaven, there is a universal underpinning that death is a condition of hopeful transformation. This mythic ideal of transformation has arisen due to the natural decomposition process, whether from burial or cremation, and in light of this, if life is to be meaningful there needs to be a sense death is one aspect of living representing entry into another form.

It is also generally accepted that all secular narratives place death as the core element, and that whether secular or religious, the narratives have a similar underlying theme of "death as living leading to transformation." The concept of death and associated mythic meanings of change are embedded in narrative through a series of connected metaphorical layers of narrative patterns, words, and visual symbols.

Textual Myths: The Quest and Death of the Hero

Across cultures, myths rely on a central characteristic of undertaking a quest. In these quests there

are sections of plot, such as call to change, overcoming personal issues, finding personal understanding, overcoming real or imagined monsters, and achieving a goal, all of which lead to the death of the hero. These plot transformation processes allow us to read and see firsthand the transformation in life of a fictional character and how life can be a preparation for death.

Because of our universal fear of dying, all of the death aspects related to a fictional hero are also linked to the need to comprehend the inevitability of our own death and our fear of purification. Although far removed from us in time and place, the function of these mythic encounters is to both allow us to continually confront this fear as well as reveal afresh how someone else answered the three great "life questions" as they came to face the one common human denominator of death. These death experiences take many forms but are typically linked in some way to the concept of sacrifice, in that living and dying for others is the path to finding genuine fulfillment in this life, leading to transformation into the next. The textual facets of death are as follows:

The Scapegoat Death. It has been suggested that this mode of heroic death occurs in some form in all narratives. Embedded in all cultures and in all of the major religious literature, this facet is typically linked to the notion of a messianic figure expunging all sin through a sacrificial death. The notion of the scapegoat is a long-held precept and predates the contemporary narratives of Christianity, Islam, and Judaism by millennia. The occurrence and need for a scapegoat death is a metaphor for the existence of social disorder and chaos in a culture when the hope for peace and security has faded and there is a need for cleansing or a new beginning. Mythically speaking, the point of this form of death by a leader is sacrificial in that their death is in place of that of another member of society. It is, therefore, the pinnacle of mythic narrative, as this single death is the transition point among disharmony, disunity, and the ushering in of a new order of peace. This mythic death narrative underpins many religious narratives in that belief in a scapegoat figure ensures transformation after death into a new eternal life of peace. It is accepted in this field of research that the death myths of Christ, Mohammed, and Buddha all have aspects of this narrative form.

The Heroic Death. Linked to the notion of the "good death," or the death that results from a battle with evil, this mythic form serves to usher in an era of peace. However, the "heroic death" also reveals how alone the hero is, thus relating to the solitary nature of death. Almost always a male, the hero is the victorious warrior. Having high social status, he is able to fit well into that social scene. But his death narrative reveals the sense of isolation all humanity encounters at the end of life. This death myth is often revealed as a massive fall, being struck down by a powerful blow. This idea of "falling" is a metaphor for one's humanity and ultimate end. Current drama and action movies such as *300, Sin City,* and *The Departed,* use this form of mythic narrative, as do the current television series dealing with the afterlife and police investigations, and many animated visual forms.

The Maternal Death. While there are few female heroic central characters in narrative, and therefore few heroic deaths, the female death motif is nonetheless an important facet of myth storytelling. Just as the heroic male death is linked to sacrifice, the female death in myth is linked in a similar fashion to the concept of martyrdom as a transformative death. Rarely is the female death portrayed in the same light as the powerful death of the male warrior form. Even when there is a portrayal of the female combatant, her death is often portrayed as either one that occurs in childbirth or metaphorically linked to the birth experience; itself a mythic metaphor of transforming from one world to the next. Although the male dies a powerful warrior death portrayed as a fall, the female dies a painful death being bound or as she either literally or metaphorically gives birth to a new "warrior-to-be" child. This form of mythic death experience is seen to be one of submission, wherein the female is willing to give her life as part of the female role so that another may live. While submissive in mythic terms, it is not secondary to the male death or role in life but more substantive in that it is only through the female that life can begin. The maternal death form is also emblematic of the life cycle myth, as it prefigures the conception of the warrior or hero in the bridal bed, and the possibility that he too will finally die as he was born, immersed in blood and suffering, having his

own flesh ruptured. For mythic researchers, the story of Joan of Arc and, more recently, the female movie deaths of Carrie White in *Carrie,* Spiderman's girlfriend Gwen Stacey, and Ellen Ripley in *Alien 3,* all represent this form of death experience.

The Evil Death. While conflict between good and evil is a major theme, this encounter has several meanings. Often cast as a clash between light and dark, the opposition to the heroic force is almost always deemed deserving of death. Good must prevail and destroy this source of evil energy. And while death comes to this being, this war represents the hero fighting against self and the evil within. The evil shadow that is being portrayed represents the evil in us all, thus making us deserving of death. If the hero does not suffer a martyr's death, then this causality is often revealed at the end of the narrative, with the heroic figure being overcome by the dark twin of death. The death of Gollum in *Lord of the Rings* is a case in point.

Words and Death Mythology

Lexical terms such as *grave* are an obvious reference to death. However, despite the personal and cultural variations, narratives also contain an array of words that prompt one's contemplation of death. These include terms such as *skull, crucifixion,* and *eternity*. This pool of language is believed to be based on narratives we hear as children. However, concepts such as *bereavement* eventually become taboo subjects. Elements of the afterlife abound in children's stories, but these words remind us of our mortality.

Thus, these words create focused projections of past narratives, personal encounters, and images of death that we have seen or experienced. In a sense, these projections forecast our demise and thus force us to confront a reality that extends beyond the experience of everyday life to include the concept of life after death, spirituality, and religion.

Visual Depictions of Death

Perhaps the most cogent form of mythic symbolism is the use of shapes, lines, and connected visual elements that are found in buildings and paintings. Even the most simple forms, such as circles, and all forms of places of worship have a deep spiritual meaning. One example is the circle of Neolithic times that symbolizes the conjoining of earth and sky. Over the millennia, this meaning has transformed into the zodiac sign of Gemini, the wedding band and its hope for eternity, the four gospels of the Christian cannon, and overarching representation of atonement and freedom from the bonds of death.

In recent times, the depth of meaning of these symbolic forms is increasingly being realized. Mythologists, archeologists, and ethnographers have made connections between the death masks found in Asia and the animal motifs and depictions of knots and circular patterns found elsewhere on churches, temples, and mosques. In relation to death, there is a vast array of visual emblems that are recognizable through the simplest of forms. One example of an ancient emblem is the Christian cross that adorns graves around the world. It is a physical marker of death, but it also symbolizes the hope of new life and a new beginning. The cross represents the heroic death of a messianic figure willing to assume humanity's evil. This symbolism is derived from the Neolithic death narrative of Tamuz, son of Astarte, a prototype story for both Christian and Jewish messianic narratives as it details the virgin birth of Tammuz, his sacrificial heroic death, and his mother's rebirth on the winter solstice of December 25. Scholars view the continuation of this death narrative as being manifested in the Christian memorial of serving Hot Cross buns at Easter, with the cross representing the "T" for Tammuz and Easter being a modern linguistic version of Astarte. Death as myth simply becomes translated into similar patterns that hold different cultural meanings.

Across time and cultures, the site of death has been marked by similar illustrative rituals that articulate death as both an end as well as a new beginning. Perhaps the oldest iconic element that deals with death and life is the labyrinth. While now representing a circle, such as a wedding band, the circular spiral form represents descent into death as well as the path that leads away from death. The labyrinth represents an enduring symbol found in burial and funeral sites across the globe in elements as simple as patterned tiles on graves. It is through mythic analysis that this form can be seen as emblematic of the cycle of life that

includes death as an integral component, all in a world that appears to have been demythologized.

Near-Death Experiences

Because of 20th-century advancements in resuscitation technology, people in numbers unprecedented in human history were returning from the brink of death reporting distinct psychological experiences with transcendental and mystical features that profoundly changed them. In 1975, psychiatrist and philosopher Raymond Moody Jr. first termed this as a near-death experience (NDE) and informed the public and most professionals about NDEs. By 2005, authors had published numerous books and over 800 refereed journal articles on the subject. In these publications, researchers reported on more than 65 studies involving over 2,500 near-death experients (the people experiencing NDEs). In these studies, they addressed the content and aftereffects of NDEs, the circumstances and incidences surrounding the experiences, and the characteristics of near-death experients. Researchers and NDE theorists also addressed the implications of NDEs for an understanding of death and the nature of consciousness. Following is a summary of 30 years of research and theory on these topics, as well as future directions in the field of near-death studies.

NDE Features and Aftereffects

Researchers have divided NDEs into two categories based on their predominant emotional tone and content: pleasurable and distressing. In both types, most near-death experients are adamant that their NDEs were as real or more real than their usual experience of reality and that their NDEs were different than dreaming, hallucination, or other familiar or known altered states of consciousness.

In pleasurable NDEs—those dominated by feelings such as peace, joy, and love—the number and combination of reported features varies but includes one or more of the following: total peace; separation of one's consciousness or sense of self from the body; observing the body and/or its surroundings; rapid movement through a non-earthly tunnel or void, usually toward a light; entry into the light, then perceived as an all-knowing, all-loving being; a life review, involving re-viewing and reexperiencing every moment of one's life and, simultaneously, being everyone on the receiving end of one's actions; encountering beautiful scenery and/or music; encountering deceased loved ones or other spiritual entities with whom one communicates telepathically; encountering a border or limit; and either voluntary or involuntary return to the body, which the experient may not specifically recall or may recall having been through any of a variety of bodily locations such as the head, chest, or whole body. Near-death experients usually report a sense of timelessness in the NDE and sometimes report omniscience and/or having been shown past lives or future events.

Physical aftereffects of pleasurable NDEs can include a sense of confinement in the body that usually resolves relatively quickly; light and sound sensitivity that may or may not linger; increased allergic and medication sensitivity; and electromagnetic

effects in the experient's vicinity, such as the malfunctioning of lights, computers, cell phones, and watch batteries. Short-term psychological aftereffects can include anger, sadness, and/or longing related to a sense of loss of the often profoundly pleasurable NDE; relief at being alive; frustration at the inability to adequately describe the ineffable/indescribable quality of the NDE; fear of being disbelieved, pathologized, or demonized; and withdrawal from others or preoccupation with telling others about the NDE. Long-term psychological aftereffects can include a total loss of fear of death (an almost universal experience following pleasurable NDEs); an increased sense of self-acceptance; empathy for others; caring and love for humanity; an appreciation for nature and life; altruism and sense of service; a sense of detachment; a sense of alienation; compulsion to read and learn; a decreased tolerance for violence; and a decreased interest in wealth and fame. Social aftereffects can include isolation or frequent retelling of the NDE; testing in social relationships to determine safety to disclose the NDE without fear of negative reaction; family and friend relationship stress and changes related to the experient's psychological changes, including increased incidence of divorce; and career changes, often in the direction of greater social service. Spiritual aftereffects can include an ongoing sense of connection to a higher power or domain and/or to humanity, life, or the cosmos; religious or spiritual difficulties, especially if the NDE diverged profoundly from the experient's previous worldview, as it often does; leaving or becoming more deeply involved in organized religion; increased psychic experiences; ability to heal others; and an enhanced sense of meaning in life, especially that the purpose of life is primarily twofold: to develop in the capacity to love and to learn—to acquire knowledge.

Much less frequently, some near-death experients report NDEs dominated by distressing feelings such as confusion, powerlessness, isolation, guilt, or horror, usually resulting in terror. Researchers have identified four types of distressing NDEs. Most distressing near-death experients have reported the same features as pleasurable NDEs but feeling fearful, which some researchers believe is associated with near-death experients' resistance to the unfolding NDE. Next most often, distressing near-death experients have described hyperawareness of total isolation in an absolute and eternal void. Even less frequently, distressing near-death experients have described "hellish" experiences involving torment and suffering. Rarest of all are reports of feeling negatively judged by a higher power.

Aftereffects of distressing NDEs are quite similar to those of pleasurable NDEs except for a higher incidence of relief at being alive and lower incidence of the loss of fear of death—at least in the short term following the experience. Most distressing near-death experients perceive the NDE as a warning and respond by reforming themselves in some way. For a variety of reasons, some near-death experients foreclose on reflection on the experience, and a few retain an open, searching attitude regarding the experience and its meaning for their lives.

Incidence and Characteristics of NDEs

Research has not yet clearly revealed the exact incidence of NDEs. Different types of studies have yielded rates ranging from 10% to 35% of people in situations of actual or threatened severe illness or physical or emotional injury. Researchers continue to debate NDE incidence.

No demographic variables predict whether or not a person in a near-death situation will later report an NDE or whether, if an NDE is reported, it will be pleasurable or distressing. Nonpredictive variables include age, sex, socioeconomic status, education level, sexual orientation, preexisting beliefs, history of prosocial or antisocial acts, mental health status, and circumstances of the near-death situation. Perhaps most notable is that both pleasurable and distressing near-death experients are just as mentally healthy as nonexperients, just as likely to have a history that includes or excludes deeds that society tends to consider good or bad, and just as likely to be devoutly religious or spiritual or disbelieving in any religious or spiritual belief system. Children's NDEs do not differ substantially from adults' NDEs. Also, NDEs resulting from combat or suicide do not differ from those resulting from natural illness or unintentional accidents—though near-death experients in general, and those whose NDEs were the result of suicide attempts, are usually strongly committed to suicide prevention because of the conviction that each life has meaning and purpose. Some researchers

have found among near-death experients a higher level of psychological absorption—the tendency to become deeply absorbed in an object of attention. However, because the spontaneous nature and relative infrequency of NDEs makes them difficult to study, it is unknown whether this characteristic occurred after, and perhaps as a result of the NDE, or if it preexisted, and perhaps facilitated, the NDE.

Because most researchers have conducted studies in the United States and other Western countries, less is known about non-Western NDEs. Members of many non-Western cultures have reported NDEs, and their content has reflected their cultures. A few features can be considered truly universal, such as encounter with spiritual entities and the experience of an otherworldly social system. Another possibly universal characteristic is encountering a border or limit beyond which near-death experients sense they would not be able to return to physical existence. Most researchers have concluded that culture clearly contributes to, but does not entirely explain, NDEs.

Implication of NDEs for Understanding Death and the Nature of Human Consciousness

Most near-death experients say that, as a result of the experience, they do not merely believe, but actually know, that their consciousness will survive their physical death. Some people who have not experienced, but have learned about, NDEs have drawn similar conclusions. However, from a purely scientific perspective, NDEs cannot provide evidence of the *ongoing* survival of consciousness, because no experient *remained* dead. To scientifically study the phenomenon of *ongoing* consciousness, researchers would need to directly study people who are *irreversibly* dead—a notoriously difficult research population. Thus, from a scientific perspective, NDEs can, at best, narrow but not close the gap in the leap of faith regarding the survival of consciousness.

Another question that several authors have addressed is the "reality" of the NDE. Arguments have fallen into one of two categories: material and nonmaterial. Materialist explanations rest on the assertion that the NDE can be reduced to brain function, specifically the physiology of the dying brain. Chief among these hypotheses is that NDE phenomena are the result of lack of oxygen to the brain. Nonmaterialist explanations rest on the assertion that NDE phenomena cannot be reduced to brain function. Chief among these hypotheses is that nonphysical, veridical perception occurs in NDEs. In numerous cases of veridical perception, near-death experients have reportedly perceived unanticipated objects or occurrences in the physical world during their NDEs that, based on the condition and/or location of their physical bodies, they should not have been able to perceive—yet the perceptions were subsequently shown to be accurate. Authors and researchers continue to debate material and nonmaterial interpretations and explanations of NDEs.

Future Directions in the Field of Near-Death Studies

Despite substantial research into NDEs and their aftereffects, much information remains to be known about them. Consequently, researchers are continuing to study them, with emphasis on certain aspects. One aspect is the extent to which near-death experients manifest changes that, by the standards of any major religion, would be considered spiritual. Another aspect is the extent to which near-death experients compose an "at-risk" group (at risk after their NDEs for distress and/or dysfunction in the physical, psychological, social, and/or spiritual domains). A related aspect is how health care providers can be most helpful to near-death experients and their associates. Because NDEs typically involve near-death experients' immersion into an alternate reality that they neither expected nor felt prepared to understand or integrate following the experience, health care providers from every field—medical, mental, social, and spiritual—have a role to play in helping near-death experients and their families, friends, coworkers, and other associates. The goal of ongoing research is to determine how to promote the greatest holistic well-being for everyone affected by the NDE.

Other research directions more broadly address the nature of death and consciousness. In these efforts, researchers are attempting to move beyond the less scientifically valued collection of anecdotes toward the more valued study conducted under controlled scientific conditions. One focus of this type of effort is veridical perception: Typically,

these researchers conduct hospital studies involving targets visible only from the vantage point of the ceiling, hoping that, over time, a number of resuscitants will describe NDEs in which they accurately report the content of the target. Another focus is electromagnetic and healing aftereffects of NDEs: Researchers are conducting surveys to determine the extent of these phenomena and planning studies in which they attempt to measure the electromagnetic correlates of them.

In conclusion, advances in resuscitation technology have resulted in numbers of NDEs unprecedented in human history. These experiences provide humanity with a unique perspective on the human experience of death. NDEs are likely to continue to occur, and ongoing research into them may provide a basis for health care providers to be most helpful to people that NDEs have affected and provide novel insights into the nature of death and human consciousness.

Necromancy

Necromancy is defined as the ability of a sage, shaman, or priest to raise the dead from the grave and communicate with them as one would talk normally with the living. The word itself is derived from the Greek words of *necros* (meaning the dead, the departed, or a specific reference to the corpse) and *manteia* (which has overlapping meanings of foretelling, to summon forth, and divination).

Of all religious practices this "summoning forth" or "calling up of the dead" has perhaps the longest history and the broadest cultural practice. Seemingly common to many cultures across human history, the clearest, but still scant, anthropological evidence of this ritual places its origin, or at least consolidation as common practice, in the Neolithic Era in many areas of Europe. It is speculated that in this area it was an integral component in the worship of Saturn, who in turn became Poseidon in later centuries. While there is little direct evidence of its development, it is speculated that necromancy then became an integral ritualized component of the evolutionary growth of this form of worship as it extended into the religious polytheistic religions of the ancient civilizations surrounding the Mediterranean and the Far East. Thus it became one of the cornerstone practices in the religions of the Canaanites, Egypt, Greece, and Rome. Each of these cultures carried this practice forward as they continued to develop and expand, whereby it also became a common ritual in Persia, the greater Babylonian Empire, and the later occidental religions.

The relatively small amount of ethnographic and anthropological research reveals that in other parts of the globe, such as Polynesia and the Caribbean, necromancy has been considered to be a normal religious exercise by societies that practice voodoo. Although there is little research focus in this area, in other religions, such as Judaism and Christian communities, it is considered to be taboo. This belief is centered on the banning of this practice by texts such as the Old Testament book of Deuteronomy (18:11) and as exemplified in the narrative in 1 Samuel 28, where the witch of Endor calls up the prophet Samuel for King Saul. Interestingly, the text does not state it was a counterfeit vision or a disguised demonic form, although many Old Testament and Christian scholars assume this is the case. Herein lie the core elements for those groups that assert the validity of this practice and those that uphold its categorization as being taboo. First, a key facet of necromancy lies in the theological notion of the "resurrection." For Christianity, Islam, and Judaism, only God or Allah can genuinely breathe life into and raise the dead, and for

these religions this is commonly believed to occur at the Last Judgment. Thus, practitioners of necromancy are seen to be taking on the role of the creator and sustainer of human life, which is a theological anathema for these religions.

Related to this concept of only God being able to create or recreate life is the current debate surrounding what theologians call "the state of the dead." In regard to necromancy in particular and the concept of death in general, the contemporary focus has been on several key Old Testament verses that seem to indicate that the term *soul* means a "life force" and not an entity capable of existence of its own accord, that the body and soul are a single entity, and that death becomes an unqualified sleep until the Last Judgment. Therefore necromancy would not fit within the parameters of this theological position of the soul or life existing after death.

For these reasons, in many areas of religious practice, theological research, and religious study necromancy is considered to be perhaps the most demonic or the blackest of all religious forms. For whatever reason, it is still typically believed by many religions that "calling forth the dead" steps into the domain of the devil or Satan, who has claimed the body or the soul as his own because the corpse itself was laid to rest in the ground, which many theologians and anthropologists deem to be classed as his territory.

Thus, in some societies and religious groups, both past and present, the priests had to protect themselves through the use of various symbols, which could include a blood sacrifice as means of atonement, the drawing of a circle on the ground to represent uninterrupted protection, burning incense to symbolize the protective shielding by a higher power (and the rising of protective prayers), and the use of symbolic forms and words drawn within the circle to offer protection.

Necrophilia

Necrophilia refers to engaging in sexual intercourse with a corpse. This behavior has been referred to as a dangerous sex crime, regardless of the physical state of the victim before the act of necrophilia. The necrophile may mutilate a corpse before, during, and/or after the sexual encounter, or may simply sexually assault the corpse. In some instances, the perpetrator actually commits a murderous act and then performs an act of necrophilia upon the corpse. The necrophile is typically an individual who becomes sexually excited and aroused by viewing a dead body or simply going to a funeral home or cemetery, and who then needs or relies on the dead body to fulfill the sexual gratification.

Most individuals view the act of necrophilia as immoral and heinous, and the individual who performs an act of necrophilia as mentally deficient, having an abnormal and perverse sensuality. Although it is difficult for most people to accept that any individual could engage in this type of behavior without some type of mental abnormality, the behavior develops out of an erotic attraction to dead bodies emerging from the need to gain control by engaging with a partner who is unable to resist.

The typical necrophile is male and the typical victim is female, although a few female necrophiles, such as Karen Greenlee and Leilah Wendell, have been identified in recent years. Victims are generally viewed, by the necrophile, as substitutes for the women who have rejected him, so he resorts to corpses to stimulate and facilitate the act of masturbation. Sexual gratification, therefore, is

achieved through the engagement of sexual activities with a dead body. Although many necrophiles can and do engage in consenting sexual relationships, many with spouses, the most desired and powerful sex is with a corpse.

Necrophilia as a sexual act is not a new phenomenon. Evidence indicates that ancient people, including Egyptian, Roman, and Greek men, practiced the act of necrophilia. For example, in ancient Egypt, precautions were taken to ensure that the corpses of the wives of men of rank were not violated by the embalmers. It is also known that government agencies attempted to thwart this activity by placing guards to protect the gravesites of royalty from grave robbers and sexual predators. In the late 20th century, necrophilia became more recognized in the United States and elsewhere, as stories of serial killers having sex with their dead victims became headline news.

The American public seems fascinated with stories of murder and sex. Indeed, the lives of Ted Bundy and Jeffery Dahmer became not only front-page news, but also "movies of the week" on various cable movie networks. But these stories are not limited to the United States. Serial killers and necrophiles Dennis Nilson in London and Andrei Chikatilo in Russia, known as the "Rostov Ripper," made headlines across the world. In 2006, police in New Delhi, India, identified Surendra Koli as a serial killer, with some labeling him a necrophilic predator.

Currently, there is no federal legislation barring the engagement of sex with a corpse. However, at least 17 states have enacted statutes making the act of necrophilia a crime. About half of the states have made the act of necrophilia a felony, carrying a sentence of up to 10 years in prison.

Types of Necrophiles

Three types of necrophiles have been identified. The first is identified as the pseudonecrophile—an individual who has a transient attraction to a corpse and only fantasizes about sexual activities with a corpse. The partner of the pseudonecrophile is alive and well but cooperates in a sexual encounter that requires her to pretend to be dead. The sexual encounter is made possible when the woman takes a cold bath or shower, dusts with white powder, then lies completely still in bed or even in a coffin while the man performs sexual acts. It is of paramount importance that the female remain absolutely still, as any movement on her part, however slight, will cause the necrophile to withdraw. Should this occur, his ability to engage in the sexual act will decrease or disappear completely. Two closely related types of pseudonecrophile are the necrophile fantasy offender who, while he fantasizes about having sexual relations with a corpse, does not carry out these fantasies. The platonic necrophile, on the other hand, does not actually touch a dead body; rather pleasure and sexual gratification is gained merely from viewing the body.

The second type of necrophile is an individual identified as a regular necrophile. This individual engages in sexual activities with a person who is already dead. This individual is able to carry out his necrophile tendencies by placing himself in an occupational setting that allows for easy access to individuals who have already died. For example, the regular necrophile may be employed as a morgue assistant, funeral parlor assistant, ambulance driver, hospital orderly, cemetery employee, or assistant in a coroner's office. Gaining easy access to corpses allows the fantasy that demands sexual activity with a corpse to be easily realized. This is the most common type of necrophilia, as most necrophiles obtain bodies through their work.

A third type of necrophile is identified as a necrosadistic offender. Also known as a homicidal necrophile, the necrosadist murders his victims for the sole purpose of engaging in sexual relations with the corpse. Mutilation of the corpse often occurs; the mutilation apparently is seen as an important part of the event/ritual, as this act is thought to reduce the worth of the corpse while increasing the emotional excitement of the necrophile. The ultimate gain for this type of necrophile is the sexual gratification gained from the encounter with the corpse, not the act of murder. Although this type of necrophile is considered by most analysts to be extremely rare, examples of the necrosadist or homicidal necrophile can be found in historical as well as in recent literature, including the chronicles of Ted Bundy, John Wayne Gacy, and Albert Fish.

Characteristics of the Necrophiliac

The etiology of a necrophile is not easily identified. What serves as identifiable characteristics of a necrophile suggests differing levels of participation in

acts of necrophilia, from merely fantasizing about a sexual relationship with a corpse (the most common), to engaging in a sexual relationship with a corpse, as well as the act of murder for the purpose of obtaining a corpse for sexual gratification. Because the participation level ranges through the extremes of human behavior, the explanations are also diverse, ranging from explanations for why an individual who fantasizes and does not carry out the necrophilia act is different than another individual who wishes for a necrophilia encounter and is willing to commit murder to fulfill these desires.

Although a wide range of personality characteristics of necrophiles has been identified, many of these characterizations are inconsistent. Thus, it is extremely difficult to establish a checklist of personality characteristics for the necrophile. As a case in point, some necrophiles have been identified as heterosexual, while others are identified as homosexual. Many necrophiles indicate they engage in non-necrophile intercourse, indicating part-time perversion and part-time conforming sexual behaviors and activities. And necrophiles also have been identified as having histories of previous sadistic sexual activities. Necrophiles have been diagnosed with personality disorder and/or engaging in behavior considered by some evaluators as psychotic. But most if not all necrophiles are of above average intelligence and have normal personalities.

Necrophiles are known to engage in other forms of dangerous and unusual behaviors, including vampirism and cannibalism. The true vampire practices necrophilia, while the autovampire fantasizes about having a dead body, and is thus classified as a pseudonecrophile. Moreover, many necrophiles engage in necrophagia or the cannibalism of a corpse.

Explanations for why an individual would engage in an act of necrophilia vary as much as the explanations offered by the researchers who attempt to explain the act. Necrophiles have been identified as insensitive to others, possessing a deep hatred for women, and experience an overwhelming fear of rejection. In the latter instance, the perpetrator compensates for feelings of inadequacy inasmuch as the actual sexual activity with a corpse provides the necrophile with sense of having the victim in complete submission to his authority and will. Rejection does not happen, failure does not occur, and humiliation is impossible.

Total control of the sexual encounter and total domination over the victim appear to be among the general characteristics of all necrophiles. In addition, alcohol abuse is reported as an important factor. However, for the homicidal necrophile, alcohol may actually assist in vanquishing trepidations about killing rather than enhancing the necrophilic act. Other motivations identified include an attempt to overcome feelings of isolation and the need for comfort, being reunited with a romantic partner, having a conscious sexual attraction to corpses, and improving self-esteem. All seem to be enhanced through exerting control and power over a homicide victim.

Finally, paraphilia, defined as an erotosexual condition to which a person is recurrently responsive to and obsessively dependent upon, is noteworthy in relation to necrophilia. Paraphilia is also characterized by arousal from an unusual or unacceptable stimulus, perception, or fantasy. For individuals diagnosed with paraphilia, the stimulus is necessary to initiate or maintain erotic arousal and to achieve or facilitate orgasm. It is known that necrophilia may occur in conjunction with other paraphilias. This is important and relevant to any treatment options for necrophiles, including medications to reduce sex drive and improving social and sexual relationships.

Neomort

A term coined by Willard Gaylin in a 1974 *Harper's Magazine* article, neomort refers to an individual human who has suffered brain death but whose other biological capacities have been maintained on a respirator, possibly with cardiac assist. This entry explores the issues surrounding the potential use of neomorts as organ donors and for other purposes.

The traditional criterion of death had been irreversible cardiac arrest. So defined, death was compatible with the transplantation of certain organs, including kidneys and corneas. But the growing practice of cardiac transplantation rendered the traditional criterion no longer useful. In the past, cardiac transplantation involved the removal of the still-beating heart from one individual and the implantation of it into the body of another individual suffering from heart failure. If irreversible cardiac arrest were to remain the definition of death, cardiac transplantation would forever be an act of killing the donor. The plight of individuals suffering from failing hearts who could have their normal lives restored through cardiac transplantation prompted the redefinition of death in the 1960s.

Redefinition was necessary, for heart transplants must be made with the living heart, unlike other organs. This meant removing the beating heart from the donor and transplanting it into the receiving patient. Doing so, under the cardiac criterion of death, entailed killing the donor even if no brain function was present.

Legislation was developed to redefine death. In a remarkable show of unification, all 50 states passed the same legislation in short order. The model that "brain death" proponents advocated, now adopted in all 50 states, is the Uniform Determination of Death Act (UDDA) of 1986, Section 1, chapter 23-06-01. Effective as of July 1, 1987, this act reads as follows:

> An individual who has sustained either (1) irreversible cessation of circulatory and respiratory functions, or (2) irreversible cessation of all functions of the entire brain, including the brain stem, is dead. A determination of death must be made in accordance with accepted medical standards.

That widespread acceptance, however, did not signal an absence of criticism. First, based on various apocryphal accounts of individuals who, having been declared dead, revive, many have doubted that diagnosis of brain death that leads to cardiac transplantation is an unerring procedure. One critic likened it to execution of individuals later found, through DNA analysis, to be innocent of the crimes for which they were convicted.

Second, there was suspicion of the motives of those who advocated the brain death criterion over a previous "dead donor rule," the permanent cessation of the functions of the prospective donor's heart. Despite a wide public support for increasing organ supplies, critics argued that elevating this laudable goal over the satisfaction of the then current criterion of death was an act that elevated pragmatic utility over our commitment to fight to preserve one another.

Third, the clamor for access to transplantable organs of patients suddenly confronted with the consequences of personal irresponsibility plus the indifference to prevention of a public health policy oriented toward cure rather than prevention, together with the financial rewards to transplant hospitals of such surgeries, places the dying in the service of the salvageable.

Against all these objections, the new definition of death was legally and widely accepted. Nonetheless, a host of other troubling issues stood in the wings awaiting their consideration.

First, a choice needed to be made between requiring prior explicit consent of the prospective donor to the harvesting of organs, and presuming the donor's consent absent an indication by the donor to the contrary. Numerous other countries have a policy of routine retrieval of transplantable organs from cadavers and neomorts, grounded on a supposed inherent obligation of the individual to the society. The United States could follow this philosophical orientation to maximize the supply of transplantable organs, or it could require explicit consent from the competent donor, expressed through a public verbal wish, a signed and current donor card, or a conversation with a loved one or health care professional, in prospect of a looming demise.

While routine retrieval was rejected in the United States in place of prior consent, the threat of possible litigation prevents its complete effectiveness. Even with a signed and witnessed donor card, transplant units in hospitals are unwilling to

honor donors' expressed wishes in the face of the disagreement of any next of kin.

One suggestion is to permit procuring organs during the terminally ill patient's dying phase after informed consent has been obtained. Such autonomy-based end of life donations raise the issue of coercion in the process of obtaining and acting on consent to donation, but the issues there are not substantially different than those successfully dealt with in Oregon's procedures that permit terminally ill patients to obtain a physician's assistance in hastening death.

Gaylin's *Harper's Magazine* article suggested other possibilities offered by neomorts that highlight the need for extensive public discourse. In his novel *Coma,* physician-author Robin Cook envisioned neomortuaries, in which neomorts would be maintained on life support and used for various medical and scientific purposes. Gaylin suggests other possible uses for neomorts: training of medical students ranging from routine medical exams to practicing surgical techniques; testing of drugs and surgical procedures to decrease the likelihood of species-specific incompatibilities that might steer us away from promising therapies or toward therapies with negative effects that were not predictable based on animal experimentation and the reporting of cellular data alone; banking of organs and tissues, thoroughly typed and cataloged, to be held available for the transplantation needs of future patients; continual harvesting of renewable and multiply present tissues throughout the body; and manufacturing of hormones, antitoxins, and antibodies.

The prospect of viewing each of us as standing to the other as potential source of life extension is disturbing. Yet, for some, the prospect of a kind of life extension in service of others after our death is attractive.

Neonatal Deaths

A neonatal death is death of an infant prior to the 28th day of life. Demographers and epidemiologists define the neonatal mortality rate (NMR) as:

$$NMR = \left(\frac{Deaths^{z}_{<28days}}{Births^{z}} \right) * 1{,}000,$$

where

$Deaths^{z}_{<28days}$ refers to deaths to infants younger than 28 days old, in year z; and

$Births^{z}$ is the number of live births in year z.

Neonatal deaths are usually examined separately from other infant deaths occurring during the first year of life. This distinction is made because (a) there is very high mortality during the first minutes, hours, days, and weeks of life, and (b) the causes of death in the neonatal period tend to differ from the causes in the postneonatal period (28 days to 364 days after birth).

Primary Causes of Neonatal Mortality

In 2005, about 30% of all neonatal deaths occurring in the United States were due to prematurity, or being born before 37 weeks of gestation. Generally, the more premature the infant, the more likely death will occur. Only about 20% to 35% of babies born at 23 weeks of pregnancy survive, compared to 50% to 70% of those born at 24 to 25 weeks. Survival increases to more than 90% at 26 to 27 weeks' gestation, whereas births before 32 weeks' gestation, comprising about 2% of all births, account for most neonatal deaths and disorders.

Premature births occur after spontaneous premature labor (50% of cases), a spontaneous rupture of the membranes (30% of cases), and intentional

delivery of a premature infant for the benefit of the infant and/or mother (20% of cases). Causes of preterm birth that are the consequences of the mother's health include high blood pressure, placental problems, a previous preterm delivery, a multiple birth, and abnormalities in the uterus or cervix.

Neonatal deaths also result from structural and genetic birth defects such as spina bifida, anencephaly, and heart or kidney defects. Birth defects account for around 21% of all deaths to infants in the United States recorded during 2005. Defects where the heart and lungs do not develop fully are the most common cause of neonatal death. Abnormalities in which the infant has more or less than the normal 46 chromosomes represent a common cause of neonatal death. It is rare for embryos with chromosomal abnormalities to survive the pregnancy, but those who do will likely die within the first few weeks of life. Other less prominent causes that account for the almost 40% of remaining neonatal deaths include pregnancy related problems, such as complications involving the placenta or problems with the umbilical cord and membranes.

Variation in Neonatal Mortality

Every year four million infant deaths occur during the neonatal period. Globally, 99% of neonatal deaths are in low- or middle-income countries. The largest numbers of neonatal deaths occur in south-central Asian countries with the highest rates in sub-Saharan Africa. Worldwide, the main cause of neonatal deaths is preterm birth (28%), severe infections (26%), and asphyxia (23%).

In developed countries, around two-thirds of all infant deaths occur during the neonatal period and are often due to preterm delivery or birth defects. There has been a dramatic decline in the NMR due to low birth weight mortality, whereby almost 80% of the deaths are to birth weights of less than 750 grams. This decline is believed to be due to technical strides in obstetrics, neonatal intensive care, and policies that provide health care access to disadvantaged groups.

The NMR in the United States has fallen from 15.1 in 1970 to 4.62 in 2003. However, global neonatal mortality numbers have not significantly changed. Even though infant mortality rates continue to decrease because of widespread interventions that include vaccines and oral rehydration therapy, the proportion of neonatal deaths is likely to increase because 98% of deaths, largely due to infections (32%), occur in the poorest countries where many births occur outside of the formal health care system.

Distribution of Neonatal and Postneonatal Deaths

In developed countries, the risk of infant death is higher in the days immediately following birth and then diminishes. In contrast, the risk of infant death in developing countries increases with age. Thus, developed countries tend to have a higher percentage of all infant deaths in the neonatal period, whereas developing countries have a higher percentage of all infant deaths in the postneonatal period.

The world NMR is 30, with Africa and Asia having the highest rates at 41 and 32 respectively. Europe and North America record the lowest rates, both at 5. The postneonatal mortality rate for the world equals 47, with the highest rates recorded in Africa and Asia at 62 and 50 respectively. The 2 lowest postneonatal mortality rates are in North America at 7 and Europe at 13.

The countries with the highest NMR in 2004 were Liberia (66), Cote d'Ivoire (64), Iraq (63), Afghanistan (60), Sierra Leone (56), Angola and Mali (54), Pakistan (53), and Central African Republic and Lesotho (52). Countries with the lowest NMR were Singapore, Japan, and Iceland (1), Sweden, Spain, Slovenia, San Marino, Norway, Monaco, France, Finland, Czech Republic, Cyprus, Belgium, and Andorra (2). The United States had an NMR of 4.

However, it may be incorrect to compare mortality rates across countries because countries often define births and, therefore, infant deaths differently. For example, in Austria and Germany, birth weight must be at least 500 grams to be considered a live birth. In other parts of Europe, the fetus must be at least 30 centimeters long. In Belgium and France, births resulting from less than 26 weeks of pregnancy are automatically registered as lifeless; and some countries do not register babies who die within the first 24 hours.

Neonaticide

In 1969, Phillip Resnick documented the killing of newborns within 24 hours of their births as a unique form of infanticide, describing the crime as neonaticide. Though relatively uncommon in the contemporary experience, neonaticide typically follows concealed pregnancies that are discovered when the bodies are found, for example, in trash receptacles. Neonaticide is often the result of a new mother's efforts to hide or dispose of a live-born infant to prevent discovery of the pregnancy and birth by her parents. Neonaticides also arise when a victim's mother seeks medical attention for complications from an unassisted delivery, but disavows having given birth. The aftermath of a brief search for her child is discovery of her newborn's untimely death. Neonaticides differ from the killing of older infants and children in terms of motive, method of killing, and offender demographics.

Those who commit neonaticide tend to be young, unmarried women in their teens or early twenties. They are typically terrified of their parents' reactions to nonmarital pregnancy, fearing that their parents will banish them from their home or they will lose their parents' love and/or respect. Some also worry about the shame surrounding illegitimate births, that their futures will be negatively affected by parenting an illegitimate child, or that their paramours will desert them if they divulge their pregnancy. These women postpone disclosure, but seldom know when their babies are due and panic when labor takes them by surprise. During chaotic, unsupervised births, the hysterical mothers may harm or dispatch their newborns. Some women remain in denial about their pregnancy until close to their delivery dates and a few remain in denial even after delivering their newborns and allowing them to die in confusion-filled deliveries, complicating classification of their intentions. A few women plan to deliver then kill their newborns, but these cases are quite rare. Instead, it appears that the vast majority of newborns are killed by young mothers who are overwhelmed by the prospects of pregnancy and parenting, and who panic during delivery.

Historical Efforts to Control Neonaticide

Attempts to address the problem of neonaticide have occurred since at least 318 C.E., when Emperor Constantine outlawed the then common practice of Roman fathers killing unwanted infants under *patria potestas*. Other attempted solutions included foundling homes where families could deposit unwanted newborns, some of which were outfitted with devices that allowed for anonymous surrenders of unwelcome children. Proclamations of religious edicts and regulations were issued from many a church pulpit, but these did little to eradicate the gruesome discoveries of discarded newborns. When social and religious responses failed to work, laws were enacted to address increases in the incidence of neonaticide.

The most important law was the 1624 Act to Prevent the Destroying and Murdering of Bastard Children, which held that women who concealed their illegitimate pregnancies were to be executed if their children were found dead, even if they claimed their children were stillborn in an unassisted birth.

This British law specifically addressed the common defense at the time, that newborns discovered by authorities had simply been born dead. It also served as the basis for other nations' legal reforms, and versions of the law spread throughout Europe and into the fledgling U.S. colonies. The laws did not eliminate the killing of newborns, however, and neonaticides continued to constitute a sizable percent of homicides in Europe and the United States. Over time, public sentiment softened toward neonaticidal women and juries refused to convict based on their desire to avoid draconian penalties for pitiable defendants. The laws were then amended so that proof of intent is required.

Incidence of Neonaticide

Despite the intense media coverage that often surrounds neonaticide, documented instances of the crime are relatively uncommon in the United States. According to official statistics, the number of newborn deaths attributed to homicide averaged 25 per year from 2000 to 2005, ranging between 23 and 31 deaths per year. Before reliable birth control and access to legal abortions, the numbers were several times higher, averaging 69 neonaticides per year from 1943 (the first year reliable data on neonaticides were collated) and 1973 (the year access to legal abortions was guaranteed). The numbers have averaged 26 neonaticides per year since 1973. It is important to note, however, that these statistics do not include undetected neonaticides, which could number into the thousands according some scholars.

The typical neonaticide victim is killed through neglect or passive means rather than intentional homicide. One-third of the documented neonaticides between 2000 and 2005, for example, resulted from suffocation of the victim and another 14% were due to drowning. Victims may drown when their mothers deliver into toilets or be suffocated during misguided attempts by their mothers to silence their cries. Only 5% of the killings between 2000 and 2005 involved weapons. The other neonaticides resulted from fatal falls during delivery, exposure, or other unspecified causes.

Although female neonaticide is thought to be a problem in some countries, neither gender is more likely to be the victim in the United States. Nearly identical percentages of documented neonaticides between the years of 2000 and 2005 were males and females (49% vs. 51%). With respect to race, most neonaticide victims are white. Two-thirds of neonaticide victims between 2000 and 2005 were white, 30% were black, and 8% were other races.

Obituaries, Death Notices, and Necrology

Death is the final equalizer, but how the living interpret and respond to death and how it is presented publicly is social and cultural. Some form of public notification of individual death is common in all of the developed world and much of the underdeveloped world except in times of mass tragedies, such as war, famine, or natural disaster. The form of death notification depends largely on location in time and place of the deceased and on the social meaning of death in a particular culture and time.

There are different labels for the public notification of death; obituary, derived from the medieval Latin *obituārius,* "report of death," is perhaps the most common. Obituaries and death and necrology notices are all a means of communicating to the public, usually to selected audiences, that one among us has died. Published obituaries or death notices typically include minimal vital statistics, and some provide more personal information that further identifies the deceased and describes what kind of person he or she was. Today in the United States, almost all deaths receive some publication closely approximating the actual statistics of death.

Progress toward the egalitarian obituary, however, is yet to be realized in most cultures. Mushira Eid commented that when she began researching obituaries in the Egyptian press in the 1930s she found "a society without women." Until the late 20th century, not only in Egypt but also in the United States and many other countries, women were identified in their obituaries by their husbands or fathers, not for their own lives and often not even by their own names. Janice Hume noted the absence of women, children, African Americans, and of the poor and powerless in general from obituary pages in 19th-century America. Another example of how obituaries, or the lack thereof, reflect social status is the case of slaves whose deaths were noted only by family and by word of mouth.

Well past the time of slavery there was infrequent public notification of African American deaths, and many were buried in unmarked graves. If their passing was noted, it was because of their relationship with prestigious whites or because they were presented as role models for their race. For example, a "colored woman" was remembered in the *Baltimore Sun* in 1855 for "her loyalty to her mistress." Historically, the changing status of African Americans in the United States can be gauged by their representation in mainstream media obituaries. The current use of obituaries to announce deaths for those of all stations in life is a result of accessibility and affordability of print and, more recently, electronic media and an underlying ideal about the worth of all people bolstered by the growth of the funeral industry.

Necrologies

Another means of notifying the public of selected deaths is that of a necrology. Before the printing press made daily publication and mass dissemination of information possible, it was customary for publications to periodically disseminate lists, a

necrology, of people who had died in a given time frame. Many organizations or publications continue the practice of collecting and disseminating the names and perhaps a brief biography of people who died over the past year, since the last meeting or last publication. The necrology may be selective, as in well-known actors or public personalities, or limited to members of a particular group, such as a church or fraternal or professional organization. Less selective necrologies can simply include all people known to have died in the past year, by community or state. The practice of gathering and listing deaths of relevance to a particular audience is an old one, perhaps first practiced as early as 1731 by *The Gentleman's Magazine* of London. In 1869, the London *Times'* necrology for the year listed deaths in order of precedence: members of the House of Lords, followed by those of baronets, then those from the arts and sciences, the legal world, the professional army, and the House of Commons.

Function of Death Announcements

The announcement of death, whether labeled obituary or death or funeral notice, is a cultural artifact with variations determined by history, custom, religion, social class, gender, technology, the news media, and publishing policy. Public announcements of individual deaths, today largely products of the print news media, serve multiple functions in any given culture. Obituaries are important data for genealogical, sociological, and anthropological researchers. They can help the researcher piece together individual or family biographies, and they can inform about historical or cultural eras in the life of a community or society. For social scientists interested in documenting social-structural changes, obituaries are microlevel reflections of macrolevel realities. For survivors, obituaries are a part of the process of grief management, informing the public about a death and often including content for the purpose of impression management. Many obituaries serve as a tribute to the deceased and to his or her life accomplishments and community service; therefore, they present positive, selective facts. News obituaries, typically written by journalists about well-known people either in the national or local arena, in addition to announcing the death of a public figure, have historical significance and serve as a kind of collective memory. Local obituaries register the deaths of ordinary citizens as a public service, and national or international publications register the deaths of the famous, infamous, and the powerful. In recent years, particularly in capitalistic societies, obituaries have taken on an economic function. Many newspapers charge for printing obituaries or charge beyond a minimum number of lines. Families will typically pay for long announcements or to have a picture printed because these artifacts are a means of distributing grief and of showing respect for the deceased. Politicians and business and professional people regularly read (or have someone read for them) obituaries in local papers to learn who among their constituents, clients, customers, or the significant others of any of these, has died. In response, they will send flowers or other condolences. For some newspapers the daily obituaries are a source of revenue. For the reading public, they are an integral and important part of their newspaper.

Democratization of Obituaries

Obituaries of celebrities or public figures, known as news obituaries, appear in newspapers with national or international readership and represent a kind of cumulative history. Such obituaries are selectively written in publications once called newspapers of record, for example, *The New York Times, The Washington Post, The Times* of London, and *Le Monde* of Paris, among others. This is true of the obituaries of ordinary people selected as newsworthy by local papers. They not only pay tribute to individuals but also are representative of a community or historic era (for example, the last civil war veteran). News obituaries written by journalists, whether local or international, have a different historical significance than those written by family members, which are often more about family survivors than the deceased.

Until relatively recent times, obituaries were indicative of social status. It was not until the late 20th century that obituaries underwent a type of democratization, giving every citizen some, even minimal, publication of death. It is also a relatively recent phenomenon that information deemed socially inappropriate is not screened out of obituaries, for example, when the cause of death was

suicide or AIDS. Divorces were deleted from life histories, as were illegitimate surviving children or nonmarital partners. It was newsworthy in the 1990s when *The New York Times* began identifying deaths caused by AIDS and when papers began identifying surviving partners, including same-sex partners. Today, even those of ignoble reputation may be eulogized in an obituary if he or she is deemed newsworthy. However, the democratization of death is still incomplete; there is still an uneven quality in publications. Those deemed worthy of news obituaries still tend to be the dominant male group in any culture.

Public Announcement of Death

There are various means of announcing the death of an individual, some simple and factual, others elaborate and socially constructed. Public announcements of death have evolved from the days when the town crier or the "Death Crier" marched through the village streets, often with bell in hand, informing all within hearing distance of the latest death or deaths. Later this verbal announcement was replaced by publicly posted notices. Today death notices, obituaries, and necrology reports are recognized as a part of the publication of death; however, it is impossible to provide a uniform definition of the first two. There is a tendency on the part of the public to use the terms death notices and obituaries interchangeably, with these being differentiated largely by working definitions in some publications. Daily newspapers often differentiate the two, but some reverse the definitions of death notice and obituary, typically differentiated by free versus paid newsprint. The news obituary, however, is more clearly differentiated by the fact that it is a news story about the death of a person significant to a readership audience. The simplest, most direct, and most similar of the three phenomena, termed by some a death notice and by others an obituary, conveys the basic facts about a life and death: name, time of death, date of birth or age, and funeral information. Such brief notices of death are symbolic equalizers, as they include no superfluous information, no clues as to whether this was an important person or an individual known only to family and friends. Such limited notifications of death are little more than vital statistics, typically generated by mortuaries, and published free of charge by most newspapers, now both in print and online. These brief notices may or may not be followed by a longer obituary, usually written by a family member, friend, or sometimes by the deceased. The longer obituaries are typically transmitted to the news media by a mortuary or crematorium and are more likely than the abbreviated notice to contain information written to present the deceased in a select and positive way. Long obituaries also contain facts as to lineage, spouse or life partner, and progeny of the deceased. They often eulogize the deceased and provide markers of his or her accomplishments, memberships, and honors. The more detailed notifications of death are generally published as paid announcements; some newspapers handle them through their advertising departments. Thus, in death a person's obituary is socially constructed and cost accounted. When the brief, free death notice is not followed by a more personal and in-depth memorial to the deceased, it is usually for lack of family or because the deceased died in institutional care or outlived others who would be interested in their passing. Some journalists have expressed concern that many papers routinely run uncensored family-paid obituaries alongside the minimum-line free announcements with no differentiation, leaving readers to wonder why some people get more space and more accolades than others. There is little question, however, that the longer versions of death notice are more interesting, from both a cultural and a research perspective, than the vital statistics form.

Paid Obituaries

Publishing policy regarding death notices/obituaries is the subject of much debate by journalists, editors, and the public at large. Most newspapers have a clear policy about what they will publish and the cost. A survey by the Readership Institute found that most papers provide both free news obituaries and paid obituaries with the length and detail in the news obituary varying from the barest essential facts to expansive chronicles of the deceased. Although most newspapers have shifted the function of the in-depth obituary to a paid obits feature, they continue to offer a free minimum-line death notice so every passing life is noted, even if

the family cannot afford or chooses not to buy a longer obituary. The fact that most newspapers, both local and national, have implemented a paid obituary policy is justified by some because print and online venues are now provided. In fact, some newspapers allow family or friends to write obituaries online and the public to write messages of condolences or personal anecdotes about the deceased. However, paid obituaries remain controversial, as evident in an editorial in *The American Journalism Review,* charging newspapers with relinquishing their public responsibility by implementing paid obituaries and treating the death of a community member as a commercial venture.

The fact is that many survivors, especially family members, will pay for an announcement (some sacrifice to do so), even as the news media continue to commercialize obituaries and death announcements. Not every newspaper will provide a cost-free news obituary for every ordinary citizen. Survivors, however, need to publish the death of their family member or friend as a request for the public to share in the grief and appreciate the life of a unique individual. Notifications of death are found in the Obituaries page of any local newspaper on any given day, usually produced by family, friends, or morticians. These typical publications will contrast sharply with those professionally written (perhaps in advance of death) to mark the passing of a much loved or renowned public figure. In both cases, however, public notification is a part of the social response to death. As death is published, grief is distributed and the private pain is shared.

Organ and Tissue Donation and Transplantation

The transplantation of organs is a well-established therapeutic intervention and part and parcel of specialized surgical services in many hospitals all over the world. Organ transplantation entails the surgical replacement of irreparably damaged organs with healthy ones obtained from either living or deceased human or animal sources.

The number of organ transplants around the world is estimated at about 80,000 per year. Survival rates can vary significantly depending on many factors, such as the condition of the organ to implant, organ and receiver compatibility, the health status of the recipient, and so forth. Under satisfactory medical conditions, the rate of successful organ replacements is quite high. For example, survival rates for a patient after heart replacement surgery in the Cedars-Sinai Medical Center, Los Angeles, California, are more than 90% survival after 1 year and more than 80% after 3 years. The survival figures for patients after a kidney transplant is on average 97% after one year and 94% after 3 years; for transplantation of the liver, patient survival is 85% after one year and 80% after 3 years; and for pancreas transplantation it is 97% after 1 year and 90% after 3 years. The rate of survival for bone marrow transplantation with donated bone marrow is 73% after 1 year.

History

The first successful organ transplantation took place in 1954 after a number of years of failed

attempts. A kidney transplant was performed at the Peter Bent Brigham Hospital, Boston, Massachusetts, where donor and receiver were identical twin brothers. The recipient lived for 25 years with the transplant. However, for genetically unrelated patients the results were less promising due to the recipient's immune system rejecting the "foreign" organ. Successive trials underscored the importance of a good blood and tissue compatibility between donor and receiver in order to avoid organ rejection. Compatibility guidelines were established and issued.

A major breakthrough in the avoidance of organ rejection was the development of immunosuppression drugs: cyclosporine in 1972 and tacrolimus in 1987. This made possible the transplantation from organs other than kidneys or hearts and the transplant of tissue from living donors, such as bone marrow, with good long-term results.

The Transplantation Process

Cadaveric Organ Donation

A major source of organs for transplantation is deceased people. The most common transplantations are of kidneys, heart, lungs, liver, pancreas, corneas, and also of parts of the intestine.

A transplantation can be divided in two phases, first the extraction of the organ from the donor body and, next, the reinsertion of the organ into the body of the recipient. The lapse of time between the organ extraction and the transplantation of the organ into the patient is of utmost importance because the longer the organ is outside of the body without blood circulation and oxygenation (i.e., ischemic time) the more the organ deteriorates. A heart, for example, extracted from the donor's body, even when kept in appropriate ice-cold fluids, cannot be maintained more than 4 hours. Kidneys can be maintained for up to 36 hours.

The organs are extracted from recently deceased donors or more commonly from brain-dead donors. Brain-dead donors are deceased by reason of their brain and brainstem function being irreversibly damaged (i.e., irreversible loss of consciousness, lack of autonomous respiration and reflexes), but whose blood circulation and respiratory function are artificially sustained.

Organ donors must be relatively young and free from any systemic disease, such as cancer, infections, or transmissible diseases, that could infect the receivers. Comparatively few potential donors qualify. Ideal candidates are healthy, brain-dead donors that are dead as result of, for instance, head traumas, whose bodies are kept artificially ventilated (oxygenated) and blood circulation artificially maintained so the organs stay in optimal condition until the transplantation is to take place.

Once a deceased is assessed as a potential donor in the intensive care or emergency unit of a hospital, a nurse, physician, or personnel of a local organ procurement agency (OPO) will contact the relatives to assess the views of the deceased as well as his or her family regarding a possible organ donation. If the answer is affirmative, information is sent to the regional transplantation center, where a transplantation coordinator will instruct the personnel at the local hospital on how to care for the donor body or organs, and at the same time order the laboratory tests needed to determine the status of the organs, blood and tissue type, and so forth. The transplantation coordinator will also be responsible for choosing a suitable patient from the organ waiting list. A good match between organ and patient is a relevant factor in achieving a successful transplantation even if the developments in immunosuppression (i.e., antirejection therapies) have made it less critical than years ago.

The Organ Transplantation

The success of a transplantation largely depends on the organ and the recipient being as compatible as possible; that is, the blood group and antigens (rejection markers in white cells) of the organ and of the recipient will have to "match" in order to reduce the rejection of the alien organ by the recipient's immunity system. Except in organ donation between genetically identical twins, the risk of rejection of the transplanted organ will be a lifelong affair, and the recipient will need to take antirejection drugs on a permanent basis.

Patients in need of organ replacement are enlisted by their physicians in the corresponding organ waiting list at the local transplantation center. Patients are ranked according to several relevant factors: degree of urgency, time waited thus far on the list, distance to transport the organ, and health status of the patient. Selection among those ranked high on a list will ultimately depend on the degree of blood and tissue compatibility with the available organ(s). Some organs are so scarce, such as children's hearts,

or the patient on the waiting list is so "mismatched" by having for example an unusual blood type, that the coordinator will search into national and even international lists for an appropriate match.

The relatively few deceased who qualify as appropriate organ donors, along with the increasing number of serious conditions that can be successfully treated with organ replacement, makes human organs critical resources. As a result and because organ markets are banned in most countries, organ scarcity has led to the design of complex structures of organ distribution and sharing to ensure that most waiting patients will get a fair chance of receiving an organ.

Living Donation

Organs, commonly a kidney or parts of the liver, can also be obtained from living donors, often blood relatives (i.e., genetically related) and therefore compatible donors. The donation of a kidney and liver parts are possible because the donor can go on living with the remaining kidney, and the liver regenerates, even though there are some risks involved in the removal of the kidney or liver section and future complications. Living organ donation from genetically unrelated donors, such as spouses and friends, are also performed with comparable rates of success. Living donation among relatives can entail ethical problems in connection with familial obligations, social pressures to donate, and even the use of indirect forms of payment. Similarly, transplantation with organs from a genetically unrelated donor can entail forms of payment and money exchange that the hospital has little possibility of controlling.

Tissue transplantation is understood as the transplantation of stem cells from the bone marrow. Stem cells are unspecialized cells that have the capacity to develop into more specialized types of cells. Bone marrow transplants are used in the treatment of several blood diseases, such as leukemia and lymphoma. The aim of the procedure is to replace the damaged bone marrow of the patient with healthy stem cells after the patient has undergone radiotherapy and chemotherapy.

There are two major types of bone marrow transplants: autologous and allogeneic. In the autologous type, the patient's own stem cells in the bone marrow will be extracted before the chemotherapy or radiotherapy and then reintroduced afterward. The reason is that chemotherapy destroys not just cancer cells but also stem cells, leaving the patient without defenses to resist infections.

In the allogeneic type, the blood-forming stem cells injected in the patient after chemotherapy are transplanted from a genetically compatible donor (e.g., a genetically compatible sibling). National and international bone marrow donation programs and registries have been developed in order to find compatible stem cell donors for patients in need of bone marrow transplants and who do not have compatible related donors.

Models of Cadaveric Organ Donation

Most countries have regulations concerning the use of human organs and tissues for therapeutic purposes. Existing regulations concerning cadaveric organ donation are based on two donation models. In the "opt-in" model, organs are obtained from individuals who, when they were alive, made an explicit statement to donate (relatives may donate the organs following the wishes of the deceased). In the "opt-out" model, organs are obtained from all deceased individuals who fit the organ donor profile, except from those who, when they were alive, vetoed the donation (relatives may also veto the donation following the wishes of the deceased). The first type of policy underscores donation as an act of giving, while the second type underscores the responsibility of the collective toward patients in need of organs. Notwithstanding the policy, with the exception of Spain and Finland, the rates of organ donation are endemically low in most countries, even if variation is found due to sociocultural characteristics (e.g., Hispanics in the United States are less willing to donate) and gender (males more willing to make cadaveric donations). Also, while a few religious groups forbid organ donation, most large religions approve the procedure.

The low figures of organ donation are just one of the factors explaining organ scarcity. Advances in neurosurgery and emergency medicine have reduced the number of potential organ donors from accidents or trauma to the brain, so the hope of increasing the number of organs focuses on the increasing use of non-brain-dead donors (e.g., patients dying in emergency units), xenotransplants, and even organ markets.

Ethical and Social Psychological Issues in Organ Transplantation

Ethical, cultural, and psychological issues associated with organ transplantation touch on issues of sacrality and human mortality. The use of the bodies of the dead for transplantation purposes stirs fears of contamination and violates some sociocultural taboos. Also the use of brain-dead donors alters cultural representation of death and dying. Thus, although organ donation is defined as an altruistic and meaningful act, it has been associated with some recipient anxieties, such as the fear that some psychological qualities of the donor may be transferred along with the organ. Similarly, patients receiving organs or the family of the donor may believe that organ transplantation entails more than the transfer of an impersonal organ, but also entails part of the soul of the deceased and implies reciprocal social and emotional obligations.

A serious ethical concern related to chronic scarcity of organs is the documented existence of a widespread illegal organ trafficking (mainly of kidneys), organized by international crime organizations that profit on poor and underprivileged "organ sellers" and buyers from richer countries in need of a transplant. China, which has advanced organ transplantation programs, has been subject to international criticism for its use of the organs of executed prisoners in replacing organs in cadres and "medical tourists." Kidney transplantations, for instance, sell for $70,000 to $80,000. More than 90% of all organs in China are obtained in this way, with the executions scheduled to fit the arrival times of recipients.

The Future of Organ Transplants

Important obstacles for further developments in organ transplantations are endemic organ scarcity and problems of immunosuppression, or organ rejection. One alternative solution, still under experimentation, is xenotransplantation, transplantation with graft organs from *transgenic pigs* (pigs carrying human genes that make the organs more compatible to human recipients). However, xenotransplants imply the transgression of yet another taboo in crossing the barrier between species by merging recipient and "donor" into a chimera, a mythological being part human and part animal.

Orphans

Orphans are defined as children (age 0–17) who have lost their parents through death or abandonment. Children who have lost one parent are described as single orphans, while those who have lost both parents are known as double orphans. Those who have lost their mothers are known as maternal orphans, and those who have lost fathers as paternal orphans. The reasons children become orphans are varied. Parents may die due to physical or mental illness, accidents, natural or man-made disasters, crime, violence, war, drug use, suicide, murder, HIV/AIDS, and endemic or epidemic plagues. The death rates of young adults in countries with poor health care support and poor occupational safety are higher than in more developed

societies with effective health and welfare provision. Deaths of young adults are more likely to leave young children orphaned.

Children are abandoned by their parents for a number of reasons. Causes of abandonment may be due to political instability, asylum seeking, unwanted pregnancies, poverty, rape, gender selection (prefer boys, kill or throw away girls), government policies (for instance, one child per couple policy and no support for children of migrant workers in China), unwillingness to keep sick children (medical costs are unaffordable) or disabled children (infants with observable disabilities or deformities), imprisonment of parents, and political persecution.

Numbers of Orphans

There is no reliable worldwide estimate of orphans, although a number of international organizations have attempted to give an idea of the extent of the problem, including UNICEF, UNAIDS, and the U.S. President's Emergency Plan for AIDS Relief (PEPFAR). According to their figures in 2006, there are more than 132 million orphans (including those who have lost one or both parents) in the 5 most affected regions of the world (sub-Saharan Africa, Asia, Latin America, and the Caribbean). They estimate that over 10% of all orphans in these regions have lost both parents. The percentage of double orphans out of the total population of children in sub-Saharan Africa is 2.4%, and in Latin America and the Caribbean it is 2.6%, which is 3 times greater than their worldwide estimate of the percentage of all children who are double orphans (0.8%).

If single orphans are included in the analysis, the percentage is even more alarming. Compared to Asia, Latin America, and the Caribbean, where 6% of all children are orphans, 12% of all children in sub-Saharan Africa are orphans. The large numbers of adult deaths in poverty-stricken areas is also due to a lack of safe drinking water, poor nutrition and hygiene, lack of affordable and accessible health care, infectious diseases, drug abuse, HIV/AIDS, war, racial conflict, and violence. Poor maternity care often results in high rates of maternal mortality, especially in South Asia and sub-Saharan Africa. With economic growth and vigorous attempts to eradicate poverty, the number of orphans in Asia, Latin America, and Caribbean is expected to drop. Unfortunately, the number of orphans in sub-Saharan Africa is still expected to rise due to uncontrolled and untreated HIV/AIDS.

AIDS Orphans

The numbers of orphans are extremely high in some regions of sub-Saharan Africa. Nigeria alone has an estimated 930,000 AIDS orphans. The role of AIDS in creating orphans in Uganda, Nigeria, Tanzania, Rwanda, Zimbabwe, and Botswana has been widely reported. In a study of a rural community in western Kenya, 1 out of 3 children below 18 years of age had lost at least 1 biological parent, and 1 out of 9 had lost both. Another study of AIDS orphans in Kenya found that more than 12% of orphaned children wished that they were dead, compared to less than 3% of nonorphaned children. Many of the orphaned children suffered from poor sleep, stomach problems, and had little hope for their future.

AIDS orphans were also found to have higher levels of negative mood and pessimism compared to nonorphans because of the strong social stigma and material and emotional deprivations that they experienced. They have been traumatized by watching their parents slowly die. Their bereavement is complicated by worries about their own health, as well as being seen as unclean and contagious by others.

Sudden Traumatic Deaths of Parents

Parents' death due to illness may often provide children with time to prepare socially and psychologically for the loss. In situations of violence, suicide, and trauma, the death of parents is sudden and unexpected. Additional stigma is attached to suicide because of the association with mental illness, religious prohibitions and punishments, and cultural beliefs about evil spirits. Many orphans suffer from post-traumatic stress disorder especially when they witness their parents' traumatic deaths.

Care for Orphans

Paternal orphans are often taken care of by their mothers as a single parent, which means that despite their loss, children can still grow in a supportive environment with love and care. The

situation of maternal orphans is often more difficult. Widowers tend to remarry quickly so that children of the first wife are raised by a stepmother. There are many cultures where it is harder for widows to remarry. The situation for widows in less developed regions is often harsh, as financial strain may be coupled with cultural oppression and discrimination. Widows may not be able to inherit their deceased husband's land or estate. Besides loss of income, female-headed households are vulnerable to sexual harassment and robbery.

Children who have lost both parents are often looked after by grandparents, or older siblings will take charge of managing the home. Such households are clearly vulnerable. Many orphaned children in poor countries will have to toil as child labor in order to feed themselves and are deprived of schooling. Brothers and sisters who have lost both parents may find themselves separated and raised in different institutions or by different foster or adoptive parents. These orphans will experience multiple losses, a total uprooting from all familiar social networks and affectionate relationships as well as kinship and community support systems. Generally, children thrive when they have opportunities for education, social and emotional support, vocational training, moral education and care, and where these resources are linked to intimacy between caregiver and children. This is why substitute homes with foster or adoptive parents are increasingly preferred for orphans.

Depictions of Orphans in Print and Film

In Western fairy stories, movies, and novels, there is a strong theme that originated centuries ago about the poverty and mistreatment of orphans from Cinderella and Snow White, through Jane Eyre and Oliver Twist, to Harry Potter and Lemony Snicket. One recent study of children's literature found that out of 56 orphaned children who appeared in folktales, 30 were portrayed as maltreated.

These stories serve at least three purposes. The first is to remind children how lucky they are and that they should be compliant and obedient to their parents, study hard, and appreciate what they have. The second is to suggest that deprivation and hardship are good training for resilience. Hostile environments can incubate noble characters. The third is to cultivate a sense of compassion for underprivileged people by addressing the pain and hurt of the wounded child.

Resilience and Orphans

There are real stories of distinguished people who survived being orphaned as children and who have become inspirational role models, outstanding professionals, and leaders in history. They include Nelson Mandela, Mother Theresa, and Chiang Kai-shek, all of whom had lost their fathers by the age of 9, and Queen Elizabeth I of England whose father, King Henry VIII, famously beheaded her mother when Elizabeth was 3 years old. With the experience of abandonment, fear, insecurity, and uncertainty, orphans often develop a sense of compassion for other underprivileged populations. They may have a stronger drive to serve and fight for the livelihood of deprived individuals and groups.

Orphanages and Child Welfare

With disintegration of extended family systems and neighborhood mutual help, government and nongovernmental organizations need to intervene to provide care and support for orphans and children in need. This can take different forms: institutional care, small group homes, foster care, community support, and adoption. Institutional care (i.e., orphanages) can often attract resources and funds because of its economies of scale, better promotion, and fund raising, although they are not necessarily the best solution for children. Large-scale nongovernmental organizations (NGOs), such as SOS Children's Villages, World Vision, UNICEF, Serving Our World, Half the Sky Foundation (serving orphans in China), Gaurav Youth Unity Society (serving orphans in Nepal), and so forth are promoting different forms of service structures to provide orphans with effective care. Governments often facilitate institutional care because obvious gross child neglect creates bad publicity and invites criticism of competence in public governance.

Developmental Problems of Orphans Raised in Institutions

In the late 1930s, psychologists began investigating the development of children who were brought

up en masse in institutions. Commonly cited problems include delays in emotional, motor, social, speech, and physical development; severe behavior and emotional difficulties, such as aggressive or antisocial behavior; as well as underperforming intellectually. John Bowlby subsequently developed his highly influential attachment theory. This identified the importance of the development of a secure and continuing attachment to a stable caregiver during infancy for the development of a mature and secure adult personality.

Recently, research by UNICEF has found that orphans are more deprived of education, socialization, and nutrition than their national peers. Thus, without protection of family or state, orphans are likely to face isolation, prejudice, crime, abuse, neglect, child labor, prostitution, exploitation, and HIV infection. Problems in orphanages may be caused by the lack of labor, training, and resources to provide the necessary human understanding for infants and children. Rapid staff turnover, staff burnout, and tight budgets are common problems. Large-scale orphanages in Russia, Romania, North Korea, and China have all been extensively criticized for gross child abuse and neglect in the last decade.

Adoption

Orphans can be given a new home through adoption. Formal adoptions are often managed by statutory organizations that involve the judicial system, although some countries still permit informal adoptions. However, the number of infants available for adoption in major cities in affluent societies is declining because of the widespread availability and use of contraception and, in some circumstances, termination of pregnancies. Many couples have to resort to developing countries to look for babies to adopt. Africa, China, Eastern Europe, and Asia are suppliers of children for international adoption, which has become controversial.

There were about 127,000 children adopted annually in the United States in 2000–2001, a number that has remained relatively constant since 1987. Adoptions are no longer dominated by kinship adoptions and private agency adoptions; public agency and intercountry adoptions now account for more than half of all adoptions in the United States. Adoptions through publicly funded child welfare agencies accounted for 40% of all adoptions (up from 18% in 1992). Intercountry adoptions accounted for more than 15% of all adoptions (increased from 5% in 1992). As well as a lack of adoptable American children, there are also concerns about the uncertainties inherent in domestic adoption, such as birth parents failing to give up their rights or reclaiming a child already placed in an adoptive home. According to the U.S. Department of State, more than 22,000 children were adopted from outside the United States, particularly from Mainland China (6,493), Guatemala (4,135), Russia (3,706), South Korea (1,376), and Ethiopia (732). Critics have described international adoption in the United States as modern-day slavery, child trafficking, and cultural and racial hegemony.

Finally, children are the future. Prevention of adult death through hygiene and occupational and environmental safety is crucial. Empowerment of women, education on gender equality, sanctions for discrimination against women and girls, improvements in public safety, and services for children with illness or disabilities can help reduce the abandonment of children.

Palliative Care

Palliative care is comprehensive, holistic care that concentrates on improving quality of life rather than on curing disease. The term *palliative* is derived from the Latin *palliare*, meaning to cloak. It encompasses hospice end-of-life care but is not limited to it. Palliative care is used along with treatment of disease in some situations.

In the broadest sense palliation applies to any situation when the treatment of symptoms is the focus. For instance, there is no cure for the common cold, and treatment is for relief of symptoms. Similarly, physical therapy, applications of heat and cold, and pain medications are palliative for back pain but not curative. In practice, however, the term *palliative care* refers to relieving suffering and improving the quality of life of patients experiencing life-threatening or life-limiting complex, serious illness. Palliative care is appropriate for patients at any stage of illness.

History

Palliative care has been part of health care for centuries. In the 4th century C.E., early Christians were known for providing hospice care to injured travelers and the seriously ill and dying. Fabiola, a Roman noblewoman, provided financial support and served as a nurse in hospice care and gave impetus to the movement.

The modern palliative care movement began in the mid-1960s. Dame Cicely Saunders established St. Christopher's Hospice for the care of the terminally ill in England in 1967. Her focus was relief of suffering and compassionate support for patients at the end of life. The hospice movement began in the United States in 1974 through the community-based home care program in New Haven, Connecticut. The first hospital palliative care program was also established in 1974, at St. Luke's Hospital in New York City. The hospice and palliative care programs focused on relief of pain and other symptoms as well as the emotional and spiritual concerns of dying patients and their families. More hospital-based palliative care programs began in the 1980s. Since then, the number has increased to more than 1,200. Over half of U.S. hospitals with 100 beds or more have a palliative care program.

The American Academy of Hospice and Palliative Care Medicine was established in 1988 to provide certification and continuing education for physicians who are in palliative care. The academy's focus is the "science of comfort and the art of caring" in life-limiting or chronic illness. In the early days, physicians in the palliative care movement often felt as if they were second-class citizens among their medical colleagues. Hospice and palliative care medicine is now an established subspecialty in medicine.

Care Recipients

Palliative care may be delivered in the hospital, nursing home, in-patient hospice, or at home. The patient and family are the recipients of care and are at the center of the health care delivery model.

Programs are available for patients of all ages, including children, and at any stage of illness. The care providers work together as a team to help relieve suffering and improve quality of life.

Patients with complex, life-threatening, or life-limiting illnesses are the recipients of care. Some of the medical diagnoses are cancer, cardiovascular disease, respiratory disease, kidney failure, Parkinson's disease, Alzheimer's disease, AIDS, amyotrophic lateral sclerosis, and multiple sclerosis. When patients are referred for hospice palliative care, they have approximately 6 months or less to live; the most common diagnosis among these patients is cancer. Other patients receiving palliative care may be receiving therapies for the underlying diagnosis simultaneously. The common factor with hospice and nonhospice palliative care patients is that they have complex health problems and can benefit from holistic, compassionate relief of physical, psychosocial, and spiritual suffering.

Funding for Care

Most insurance plans cover all or part of palliative care services in hospitals. Terminally ill patients may have coverage through their private insurer. Those who are age 65 or over and on Medicare are eligible for the Hospice Medicare Benefit. The patients and families must commit to accept the benefit with plans not to seek further curative therapies. A set daily fee is given to the approved hospice program to provide terminal illness care. If the patient improves, the benefit may be suspended and the patient will return to regular coverage. Those without insurance are served through Medicaid (the state and federal program for the indigent) or through charity services of the hospital or hospice program.

Interdisciplinary Team

Palliative care providers include professionals and volunteers. All have special education and training in palliative care. A physician, usually an internist or family practitioner, leads the team and writes the orders for therapies to be used. A psychiatrist (also an M.D.) may participate to determine psychological needs and medications that may be helpful. One or more nurses help to develop the plan of care and direct care to patients and their families. A clinical psychologist or social worker may serve in a counseling capacity. Social workers also help to resolve financial issues. Pharmacists provide consultation about appropriate medications, especially those for pain control. A chaplain is available to assist with spiritual aspects of care for the patient, the family, and the staff as well. If the patient has a spiritual advisor, the chaplain may serve to encourage and facilitate that relationship. Other professional team members may be a physical therapist, a music therapist, a specialist in therapeutic touch or massage, or an acupuncturist.

Volunteers serve an important role in the care of hospice patients. They may be assigned to a family in home care and provide companionship, assist with errands, bring meals, or do whatever will be helpful to the family and the patient. They are required to participate in a volunteer training class prior to making the visits. The volunteers do not perform direct patient care but provide support in a variety of ways.

Palliative Care Practices

Dame Cicely Saunders described the physical and psychological distress of seriously ill patients as total suffering. The goal of palliative care is to help the patient find comfort and relief from the suffering and to enhance quality of life as long as the patient lives. That may include helping them prepare for approaching death. The implementation of palliative care does not preclude the continuing use of more active therapies by the primary physician or oncologist. Even with hospice patients, radiation and chemotherapy may be continued for pain control and symptom relief. The palliative care team works closely with the primary physician to assure that palliative practices complement the ongoing active therapies.

The palliative care team members do an initial assessment of the physical, psychosocial, and spiritual needs of the patient and the family. This is an essential first step in determining the priorities of care.

Pain is often the physical symptom that is creating the greatest stress. When the patient is comfortable, other issues are much easier to address. Ideally, the physician, the patient, the family, the nurse, and other providers confer to determine the medications and their administration to provide the most comfort without unpleasant side effects,

such as somnolence or confusion. Other complementary modalities may be gentle massage, acupuncture, or guided imagery to help in pain relief.

Nausea may accompany chemotherapy or radiation treatments or be a result of the underlying disease process. The palliative care team uses appropriate interventions to help reduce this annoying symptom.

Loss of function symptoms, such as urinary continence or mobility, also creates distress and may affect the patient's coping ability and relationships with family. If the patient is at home, the family caregiver may have difficulty knowing how to assist the patient as function changes. The team members may suggest a urinary catheter to assist the patient, keep the skin dry, and make care easier for the family member. Additionally, the team physical therapist is available to help the patient increase mobility as much as possible. The patient can have benefit not only by being able to be more independent but also by the sense of accomplishment and relief that care is easier for the family member.

Other physical symptoms may be swelling that is creating pain, inability to talk following a stroke or surgery for a brain tumor, changes in vision or hearing, or amputation. The palliative care team can help the patient get needed help with these and other physical problems that are creating distress.

The team is very concerned with the psychological stress of the patient and the family member. Active listening is a skill that is crucial to all the team members. The patient may express signs of depression, suicidal tendencies, relationship problems with family members, and other emotional problems. The good listener who spends time with the patient can identify the major concerns. Often the patient will share thoughts and concerns with the care team member that he or she cannot easily talk about with a family member. Additionally, treatment with a mild antidepressant may reduce a patient's distress and improve coping skills.

Spiritual support is appropriate for all patients and families, whether or not they have a religious preference. The chaplain or another team member may do a spiritual needs assessment to determine how the team might be of support, particularly with the stress of a life-threatening diagnosis or approaching death. Listening to the patient's concerns and questions about why things are happening, where God is, and what the patient's relationship to God consists of is often very helpful so that the patient may move toward personal answers or simply feel free to raise questions out loud. Some patients find that doing a life review, either orally or in writing, helps them to identify positive accomplishments and values to pass on before they depart. Writing or other creative efforts may be helpful to both patients and family members as they cope with the situation.

Family members are included in palliative care. They participate in planning the care for the patient, and they are given emotional and spiritual support as needed. The primary caregiver in a home situation is offered respite care to take a break and get rest and emotional refreshment.

Palliative care is comprehensive and is individualized for each patient and family. All involved mutually agree upon the assistance that the team gives. The patient and family choose whether to participate in a formal palliative or hospice program and may discontinue services at any time.

Education for Palliative Care

In the past, medical and nursing education programs had little content on end-of-life care. A 2007 study reports on a survey of 122 medical schools and 580 baccalaureate nursing programs to determine the curriculum content related to death education. All of the medical schools and 99% of the nursing programs surveyed had some content, but the average number of hours was less than 15.

There are a number of medical schools, however, that have been proactive in developing palliative care centers and educational programs. The Center for Palliative Care of Harvard Medical School in Boston began in 1996 under the leadership of Loring Conat, M.D. It is a collaborative program with Massachusetts General Hospital, the Dana Farber Cancer Institute, Brigham and Women's Hospital, and the Children's Hospital of Boston. Medical students take palliative care courses in their first and second years of study and work directly with dying patients and their families. Internists or family practice physicians are eligible to apply for a 1-year fellowship program in palliative care. Continuing education programs for physicians, nurses, and other professionals are offered throughout the year. The center has publications on various topics related to palliative and end-of-life care.

From 1996 to 2006 the American Academy of Hospice and Palliative Care Medicine awarded subspecialty certificates in hospice and palliative care to 2,883 physicians in the United States. In September 2006 the National Board of Medical Specialties approved hospice and palliative care as a subspecialty in medicine. The National Board of Certification of Hospice and Palliative Care Nursing certifies advanced practice nurses, basic registered nurses, licensed practical nurses, and nursing assistants in various aspects of hospice and palliative care as well.

Pediatric Palliative Care

Pediatric palliative care is both a philosophy of care and an organized program for delivering care to children with life-threatening conditions and those children's families. The recognition that the child and the family are the unit of care is the foundation upon which palliative care is based. Palliative care promotes clear and culturally sensitive communication among the child, family, and their primary caregivers that assists the family to understand the diagnosis, prognosis, and benefits and burdens of treatment options. It is an integrated approach in which medical science and humanism are merged with the goal of addressing physical, psychosocial, and spiritual needs of these children and their families. It is achieved through an interdisciplinary approach that uses a combination of active and compassionate therapies designed to enhance quality of life for the child and family, thereby minimizing suffering, optimizing function, and providing opportunities for personal growth. Pediatric palliative care is not simply providing care at the end of a child's life; the pediatric palliative care philosophy should be implemented at the time of diagnosis and continue through the child's death, attending to families' needs during bereavement. Palliative care is appropriate over the continuum of a progressive, life-threatening condition and may be initiated in conjunction with curative treatment.

History of Pediatric Palliative Care

The hospice movement that began in the 1960s with the establishment of St. Christopher's Hospice by Dame Cecily Saunders in London, England, laid the foundation for providing care for individuals with life-limiting illnesses and their families in specialized locations. In the United States, the hospice movement grew from a grassroots beginning with most programs designed as home care support. The hospice concept was adapted to hospital settings of caring for the dying with the establishment of the first hospital-based palliative care unit in Montreal, Canada, established by Dr. Balfour Mount, who coined the term *palliative care* in 1972.

The development of palliative care for children followed the early footsteps of adult models of care and thus has a more recent history. Loci of care available for palliation in children can be loosely categorized into inpatient, primarily tertiary care children's hospitals, or domiciliary facilities and outpatient or home-based programs. In some places, home care programs are coordinated through inpatient facilities. In addition to the standard

hospital, there are freestanding palliative facilities, commonly referred to as hospices. The first of these, Helen House, established in England in 1982, led the way for the establishment of nearly 40 similar facilities throughout the United Kingdom and for the first freestanding children's hospices in North America (Canuck Place in Vancouver, Canada, in 1995), in Australia (Bear Cottage in Sydney in 2000), and in the United States (George Mark Children's House near San Francisco in 2004). In Canada, the hospice concept was applied to children's hospital settings in the mid-1980s with pediatric palliative care programs in both Toronto and Montreal Children's Hospitals. In the United States, the early pediatric palliative care movement was primarily directed toward supporting the dying child and family in their home environment, beginning with Dr. Ida Martinson's pioneering the first home care program for dying children in Minnesota in 1972. The first U.S. hospital-based pediatric palliative care program started in 2001. In hospitals, the pressure for delineated areas for children receiving palliation came originally from those services carrying significant numbers of children with chronic illness in their terminal phase, such as oncology and cystic fibrosis services. In the past decade, many children's hospitals have instituted palliative care programs to provide support and follow-up to children with these and other life-limiting conditions.

As the field developed, professional and national organizations became involved in pediatric palliative care. The Association for the Care of Children with Life-Threatening Illness, based in the United Kingdom, and Children's Hospice International, based in the United States, were among the first. In the United States, the Institute of Medicine report on the status of end-of-life care for children served as an impetus for attention to pediatric palliative care. National groups such as the National Hospice and Palliative Care Organization in the United States, the Canadian Hospice and Palliative Care Association, and the European Association of Palliative Care actively support pediatric palliative care endeavors; standards of practice have been developed. Various medical and nursing professional organizations have published position papers pertaining to pediatric palliative care. The number of research reports and textbooks has increased since 1993, when the first publication pertaining to pediatric palliative care appeared in the first edition of *The Oxford Textbook of Palliative Care*. Finally, joint projects have contributed to improvement of pediatric palliative care within host countries and, more recently, across the world.

Differences Between Pediatric and Adult Palliative Care

Compared to palliative care for adults, certain concerns are unique to or particularly evident in children. Foremost, the death of a child is never viewed as normal or natural and always as tragic, unlike our customary expectations of death as a natural phenomenon in an older adult.

Smaller numbers of children die, compared with adults, and from heterogeneity of illnesses, some of which are familial in nature; thus, more than one family member may have the same condition. Many pediatric illnesses are rare and follow irregular disease trajectories, making diagnosis, prognosis, and medical management even more difficult and uncertain than it is for seriously ill adults. Advances in technology and pharmacology have produced benefits, enabling the survival of many children who might otherwise have died from life-threatening conditions, such as extremely premature newborns or children with congenital cardiac abnormalities. In all such cases, the ethics of care forces the question of whether aggressive care is always justifiable. Ongoing discussion considers this question, along with questions pertaining to uncertainty, quality of life, and assent and consent. Even when death is imminent, the need exists for blending of curative and palliative care models; optimally, initiating palliative care principles should occur at diagnosis even though complex ethical, legal, and health policy issues affecting children further complicate the timely provision of pediatric palliative care.

Children are not small adults. Obvious physiological and pharmacokinetic differences between children and adults influence management. Developmental differences must be considered when dealing with pediatric patients who range from neonates to adolescents and young adults, and managing their care must adapt over time as they change developmentally (i.e., cognitively, emotionally, physically). Furthermore, focusing on the well-being and suffering of the family takes on greater emphasis in pediatrics. Parents are integral to the

care team, as they are direct caregivers, legal guardians, and decision makers for their child. Siblings and peers are greatly impacted by the illness and death of the ill child; grandparents too have unique needs. Language and cultural variances, cognitive development, and family dynamics must all be considered. As a result, the care team often comprises a wide variety of professionals, including child life therapists or school teachers. Most children with serious illnesses are treated in tertiary care centers, often far from their home communities. When children leave the hospital, an adult palliative care service or community hospice may be the only available source of hands-on pediatric care. Thus, despite the salient differences between the adult and pediatric realms, adult-focused practitioners may also be members of the pediatric palliative care team.

Population Served

As expertise in pediatric palliative care expanded, the importance of developing services for children with conditions other than cancer was acknowledged. Four patterns of disease progression describe children and adolescents requiring palliative care:

1. Conditions for which potentially curative treatment has failed (e.g., malignancy)
2. Conditions for which intensive treatment may prolong and enhance life, but premature death still occurs (e.g., cystic fibrosis)
3. Progressive conditions for which treatment is almost exclusively palliative but which may extend over many years (e.g., neurodegenerative conditions)
4. Nonprogressive neurological conditions that result in an increased susceptibility to complication and premature death (e.g., severe cerebral palsy)

Palliative care services for children continue to be underutilized. In the United States, it is estimated that more than 50,000 infants, children, adolescents, and young adults (up to age 24) die annually from the complication of a complex chronic condition. On any given day, it is estimated that 5,000 of these patients are within the last 6 months of their lives. Most children's deaths in the Western world occur in hospitals, and most of these, in neonatal or pediatric intensive care. Children with a complex chronic condition who die in hospitals are likely to experience periods of mechanical ventilation and hospitalization before death. In addition, accidental deaths remain the leading cause of deaths in children and adolescents; many of these deaths occur in emergency departments or pediatric intensive care units. Even if the time in hospital is brief due to traumatic injury and subsequent death, all salient principles of palliative care are fully applicable.

Barriers to Optimal Pediatric Palliative Care

Several barriers to providing optimal pediatric palliative care have been identified: fear and denial of the child's prognosis, silence about the topic of death among practitioners and families, uncertainty of outcomes, and delayed identification of the need for palliative care; limited financial resources for specialized pediatric care, fragmented follow-up care after discharge from hospital to the community, and limited access to specialty care in rural areas; inadequate assessment and management of symptoms, communication problems, and inattention to psychosocial and spiritual issues; false hope for cure, inappropriate continuation of advanced life-saving technology, and ethical and legal issues; lack of research on pediatric palliative care; and lack of training and expertise among health care providers.

Ongoing development of pediatric palliative care must address these barriers. Several barriers are associated with the clinical context in which palliative care is provided. Specialized time, expertise, and resource requirements are essential for providing care to children with life-threatening conditions. It is recognized that limitations in funding and staffing are paramount concerns and can restrict providers' capacity for providing the specialized palliative care needs of critically ill children, as well as restrict capacity to create environments that foster communication and attention to psychosocial concerns of children, families, and health care professionals. The inadequacies of professional education and training in end-of-life issues have prompted leaders in the health care community to target these issues for intensive reparative efforts. Enhancing the interdisciplinary

collaborative nature of practice and fostering instructional mentoring relationships to improve palliative care for children and their families are increasingly being implemented. Because working with terminally ill children is intense and sometimes overwhelming, attention is being directed to the needs of health care providers.

Other barriers pertain to the underlying situation of uncertainty in confirming a diagnosis, predicting prognosis and disease trajectory, or predicting treatment response. Moreover, uncertainty motivates families and providers alike to continue curative treatments that may delay or limit the discussion of the possibility of death until late in the disease course. Historically, palliative services were initiated when curative therapy was no longer appropriate and the child was "dying." However, all children in the categories of life-threatening illnesses are at risk for premature death. Therefore, the initiation of palliative services is based more on the underlying disabilities (physical, emotional, and spiritual) that the illness brings to the child and family as well as their underlying needs for support. Discussions must occur between and among providers, patients, and families about their goals, be they to eradiate disease, extend life, enhance comfort, and promote quality of life and support of the family during life and after death.

Future Directions

Provision of palliative care for seriously ill children began to garner much support during the late 20th century. Impressive improvements have resulted through addressing known shortcomings and progress continues in developing the field. Future avenues will continue to investigate ways of optimizing care of children who will likely die before adulthood and focus greater attention to the palliative care of diverse children and families within the Western world as well as in developing countries where life-limiting conditions among infants, children, and adolescents present unique challenges.

Persistent Vegetative State

Persistent vegetative state is a medical syndrome produced by brain damage. In persistent vegetative state, the patient is awake but does not demonstrate cognitive ability and shows unawareness of the self and the environment for at least 1 month. The person demonstrates no purposeful, sustained, or voluntary behavioral responses to visual, auditory, tactile, or noxious stimuli, and there is no language comprehension or expression. There is bladder and bowel incontinence and preserved cranial nerve and spinal reflex function; sleep–wake cycles may be normal. The state often occurs following coma and is caused by traumatic brain injury or oxygen deprivation. The term *persistent vegetative state* may be somewhat misleading

in some cases. In the United Kingdom, the Royal College of Physicians recommends using the terms *vegetative state, continuing vegetative state,* and *permanent vegetative state* to distinguish between early and late stages of the syndrome, and because the patient may, indeed, recover, at least partially.

Clinical Features

The brain represents only 2% of body weight but accounts for 20% of oxygen utilization. Lack of oxygenation (anoxia) for more than 2 to 4 minutes leads to rapid destruction of brain cells; the extent of injury increases with the duration of oxygen deprivation. Extensive brain damage results in brain death, and somatic death follows rapidly. The development of cardiopulmonary resuscitation (CPR), artificial respiration, and other technologies has made it possible to keep people alive after motor accidents, drowning, and cardiac arrest. Because CPR can keep the person alive for long periods of time, different levels of brain damage and consciousness can occur, depending on the duration of anoxia during the resuscitative process. If the person survives, extensive brain damage sometimes leads to a partially conscious state without purposeful behavior inconsistent with a sapient existence. This particular condition was first named *persistent vegetative state* (PVS) in 1972 by Jennett and Plum. It is different from brain death where there is no consciousness, motor function, or electroencephalographic activity.

There are several states of altered consciousness that may be confused with PVS. *Coma* is a state of unconsciousness that may or may not be reversible and can occur with or without brain damage. *Minimally conscious state* (MCS) is a condition distinct from coma and PVS with inconsistent and erratic responsiveness that may last for years. Generally, MCS has a better prognosis than does PVS. It is also different from *locked-in syndrome*, in which the patients are aware of the self and the environment but have lost motor function and speech.

Brain Death and the Definition of Death

Brain death is a state of irreversible destruction of the brain. Criteria for diagnosis include deep coma and absence of any brain-stem functions (e.g., spontaneous respiration, pupillary reactions, gag and cough reflexes). Hypothermia, drug overdose, and poisoning should be excluded. Electroencephalography is useful, but not essential, in determining brain death.

For centuries, the diagnosis of death was based on permanent cessation of breathing and the heart beat. Because of technological advances and ethical and legal implications, a restatement for the traditional definition of death was needed. A presidential commission was formed, and in 1981 it issued a report on the definition of death in the United States. Because of ongoing changes in technology, increasing sophistication in medical knowledge, and refinement of techniques, the definition of death was based on clinical physiological standards rather than solely on medical criteria and tests. This statutory definition was to be kept separate and distinct from provisions governing criteria for organ donation and termination of life support. The report does not deal with the medical, legal, and ethical issues in brain-damaged or dying patients.

Causes and Clinical Diagnosis

The most frequent causes of PVS are direct head trauma, anoxic brain damage from cardiac arrest and near-drowning, or prolonged periods of severe metabolic disruption. Other causes include hemorrhagic stroke, sepsis and serious infections, and prolonged increased intracranial pressure from tumors or abscesses.

Accuracy of diagnosis in PVS is often difficult because objective assessment of residual cognitive function is a problem since motor responses to verbal commands during neurological examination are inconsistent, variable, and may seem purposeful at times. Tests such as magnetic resonance imaging (MRI) and computed tomography (CT) scans show the extent of brain damage, but these tests cannot demonstrate functional capacity. Moreover, it is difficult to determine if and when recovery will occur. Unlike brain death, there are no agreed-upon criteria or tests that will confirm the diagnosis of PVS. However, it is more or less agreed by many experts that a diagnosis of PVS on neurological examination should have the following components: (a) wakefulness without detectable awareness, (b) lack of purposeful motor activity, and (c) lack of cognitive function. Postmortem, the brains of patients with PVS are

heavily damaged with loss of matter, reduced weight, and enlarged ventricles. The most consistent finding is diffuse axonal injury and widespread degeneration of subcortical white matter; often there is damage to the thalamus.

Prognosis

In PVS, the patient will either eventually recover, though not necessarily fully due to residual brain damage, or remain in PVS until death. Infection is the leading cause of death in patients who do not recover. In some cases, patients spend decades in PVS until death occurs. In general, prolonged survival is rare. The older the patient is, or the longer he or she has been in PVS, the less likely it is that the patient will recover.

Because of a lack of uniformly standardized medical criteria and diagnostic tests for PVS, there have been several controversial legal cases related to the diagnosis and prognosis for recovery and serious disagreement about withdrawal and termination of care in PVS. Notable controversial cases have included those of Terri Schiavo in 2005, Nancy Cruzan in 1990, and Karen Ann Quinlan in 1975. Although these cases have been extensively adjudicated in court, there is still no uniform agreement on how best to determine if life support should be continued or terminated.

Ethical and Legal Considerations

The moral, ethical, and legal difficulties with discontinuation of life support and the withdrawal of medical care are the key issues in both brain death and PVS. In the Western world, the legal definition for brain death is better established than that for PVS. With brain death, guidelines are well established for discontinuation of mechanically assisted respiration, tube feeding, and ongoing medical care in order to allow somatic death to occur. Additionally, there are guidelines for organ harvesting for transplantation in brain-dead patients. However, despite the establishment of such guidelines, ethical debates on all of the previously mentioned types of care continue. These debates about brain death are based on ethical and personal values, emotional considerations, and moral and religious views.

With PVS the situation is even more complicated because the person is not actually brain dead and demonstrates movement and partial consciousness to caregivers and relatives, in part because the diagnosis and prognosis of PVS are often unclear, and the difficulty loved ones may experience in accepting PVS as being potentially irreversible. The lack of clinical certainty in diagnosis and prognosis provides an opportunity for differences in medical opinions and for the appropriate course of action to be taken in an individual case. Inevitably, such situations lead to an appeal for legal relief to define the limits of medical care. The cases of Quinlan, Cruzan, and Schiavo were helpful in establishing the legal parameters for the withdrawal of care. Such case law has allowed physicians and families of a PVS patient to make decisions jointly in order to avoid legal proceedings.

In cases where there is conflict between doctors and patients' families, or among family members, the principle of *substituted judgment* may be applied. In substituted judgment, the law recognizes that recommendations for withdrawal of care may be based on testimony from a responsible person (e.g., a spouse, a relative, a partner, or a close friend), who states that the patient had expressed a prior wish that he or she would not desire to be kept alive on life support and would not want to have extraordinary means taken to revive him or her, should a medical catastrophe occur.

The "Do Not Resuscitate" Order (DNR)

A separate but related issue is the "do not resuscitate" (DNR) recommendation. Many physicians would also make a DNR recommendation to relatives of a patient in PVS should a cardiac or respiratory arrest occur. Before a DNR order is issued, a full neurological examination is done to establish extensive brain destruction, exclusion of the dulling effects of sedatives, toxicity from drugs and chemicals, and agreement among the treating physicians that a persistent state of severe brain damage is present. All medical consultants should agree that the prognosis is irreversible. A clinically catastrophic event should be viewed as "a natural ending of life" rather than as an abandonment of medical care by medical staff. It should also be stated explicitly to the family that the reason for recommending a DNR order and/or for discontinuing artificial life support is not based on cost consideration; clearly,

this would be unethical. Additionally, a clear distinction should be made between the DNR order and withdrawal of care on the one hand, and euthanasia and assisted suicide on the other—distinctions not always understood by the lay community.

In the United States in both PVS and brain death cases, issuing a DNR order or the withdrawal of care does not ordinarily require consent from the courts. Admittedly, the situation in PVS is a much more difficult one, and the risk of a malpractice lawsuit may prevent physicians from making a recommendation to withdraw medical care to allow death to occur. Therefore, it is essential for medical staff to document in the medical record the medical evaluation procedures, discussions with relatives or responsible caregivers, and the outcomes of such meetings. There should be complete concurrence among all interested parties (or with the person having power-of-attorney) that both withdrawal of care and the DNR order are unanimously agreed upon in order to minimize the risk of lawsuits for negligence. There remains the difficult problem of cases in which the family refuses to allow the withdrawal of care to a family member in PVS after many years of care, during which time the cost of such care is borne by the institution. In these cases, litigation may be forced by the hospital, as there may be genuine conflict between the institution and the patient's family.

Because of the possibility of irreversible brain injury in the future, some healthy individuals now make decisions ahead of time when they are still mentally competent, so that in the event of serious illness, they can advise caregivers and relatives what may be done to limit care. It is customary now in the United States to have a discussion before a major medical or surgical procedure to document the patient's wishes in the event of a catastrophe rendering them mentally incompetent. Families also often have such discussions ahead of time to document their wishes in a "living will." Many people appoint a proxy or grant a durable power-of-attorney to a responsible person to allow decisions to be made should they become mentally incompetent. Although such steps are extremely valuable in clarifying the wishes of a patient should they be rendered mentally incompetent, they do not alter or remove the ethical and medical responsibilities of the physician; however, they greatly reduce the complexities of decision making in this difficult area.

Personifications of Death

As a personification, death is portrayed as a person with human characteristics, in contrast to a functional description of death, such as "the end of life of an organism." The anthropomorphic features of death are represented in the physical appearance of death (e.g., a human skeleton) and the activities death is imagined performing (e.g., playing an instrument). In addition, death can be given a gender, clothing, personality, and voice. Personifications of death are representations of how humans imagine death. By personifying death, we reveal how we experience death, especially when death is given a particular character. In stories in which death is presented as a person, humans trick or play with death; this suggests that people want to be in control of their own deaths.

Personifications of death have been depicted in mythology, art, literature, and popular culture since 800 B.C.E. This entry overviews four themes to explicate the richness of the personification of death: (1) images of death in mythology and religion, (2) the gender of death, (3) modern images and motion pictures, and (4) the psychology of personifications of death.

Images of Death in Mythology and Religion

In Greek mythology death is represented by Thanatos, the god of death. Although Thanatos is a god, like other Greek gods, he has human attributes. He has a human body and is seen as the brother of Hypnos, the god of sleep. A classical image of Thanatos is a barely dressed man with wings who ends people's lives by a gentle touch. In this ancient representation, death is not cruel or frightening, but rather, a kind, inevitable visitor. The anthropomorphism in the illustrations of Thanatos is most visible in a painting by German artist Johannes Heinrich Tischbein, which shows the mother of death, Nyx (the goddess of the night), and her two little children, Thanatos and his brother Hypnos. In the image, the mother Nyx gently places her arms around her two sons.

In Hinduism, the god of death is personified in a human-like body, with a human face or a mask, in the form of Yama. A central attribute of this representation is a bull on which Yama is sitting or standing. The god of death holds a rope or a mace and pulls out the souls of those about to die. The gentleness in the image of Thanatos is not to be found in this personification. Moreover Yama brings justice to the world. A popular myth tells that Yama used to be a human who, just before reaching Enlightenment and after 50 years of meditation, was killed by two robbers.

Many images from the Middle Ages of *la danse macabre* (dance of death) are often combined with parts of texts from the Bible. The dance of death is a metaphor for the last struggle with death. In many images of la danse macabre, death is shown as a dancer, or more precisely, a dancing skeleton, sometimes wearing a robe or piece of cloth. Death also plays different instruments in different images, among others a violin, harp, or drum. In these images, death is touching people or pulling their clothes while showing his teeth, which gives the impression that death is laughing at his guests.

The Gender of Death

If death were a person, would it be a man or a woman? Personifications of death in Western cultures are mainly restricted to a masculine appearance, such as "the Grim Reaper," who wears a black robe and carries a scythe. In this image, death brings the message when someone has to die. However, there are cultures in which death is seen as a female. Female representations of death are often found in cultures where the word *death* is grammatically feminine, such as *la muerte* (Spanish) and *śmierć* (Polish). *La santa muerte,* the holy death in Mexico, is a female skeleton wearing a dazzling robe. In contrast to the sharpness of the scythe, she holds a bouquet of beautiful, colorful flowers and brings love, luck, and protection to the people. In exchange for the protection *la santa muerte* provides, pilgrims bring luxurious, hedonistic gifts, such as alcohol and cigars, to her altar. Worship of *la santa muerte* has been forbidden by the Catholic Church, but she continues to be worshipped by Mexican people.

In *The Young Man and Death* (1865), the French symbolist Gustave Moreau illustrated death as an attractive, young, and seductive woman with her eyes closed. Death stands behind the young man whom she wants to take with her. In French *la mort* (death) is a grammatically feminine noun, which fits perfectly in the symbolic use of death during late 19th-century art movements. In *Thanatos I* (1898) by the Polish painter Jacek Malczewski, death is a beautiful, gracious, young woman with a strong feminine body and long wings, dressed in a white robe. In Malczewski's and others' female personifications of death, she is often associated with the angel of death. Originating from the Judeo-Christian idea of a death angel, this image is also used in art to picture death as an attractive woman with wings.

One of the most famous and controversial images in history of a female angel of death is in the symbolist painting *Death of the Gravedigger* (between 1895 and 1900) by Carlos Schwabe. In this painting death is a female angel with long wings shaped as scythes, wearing a black dress that emphasizes her feminine body. The angel of death

crouches over a grave in a snowy graveyard. In the pit stands the aged gravedigger whose life is about to be taken away. Although death embraces strength and power in this image, she does not appear as a frightening figure, but rather, has the look of a gentle angel. In this image death holds a lit candle, a common symbol that indicates the approach of death. When the candle goes out, it is time to die. The left hand of the death angel points toward heaven, which can be interpreted as a promise for an afterlife.

Another important concept in the personification of death is the depiction of death as an attractive man—the motif of death and the maiden. Used in numerous illustrations, books, poems, and plays, the maiden is often seduced by death and her life taken by his temptation. Death is often depicted as having an erotic relationship with a (young) woman. The tense relationship between lust and death is reflected in paintings such as *Death and the Maiden* (1517) by Nicklaus Manuel, in which the hand of death is under the woman's dress. Matthias Claudius's poem "Der Tod und das Mädchen" describes the dialogue between death and a young girl. The girl is begging death to pass her by, but death answers that he is her friend and he will not punish her. "You will sleep peacefully in my arms" are his last words.

Modern Images and Motion Pictures

The transformation of the image of death is seen in the works of Gustav Klimt. He mixed symbolism in paintings with art nouveau, but his work was heavily criticized for its explicit reflection of the female body. In the oil painting *Death and Life* (1910–1915), Klimt depicts death as a vague bodiless robe with a skull and bony hands holding a mace. In contrast, life is illustrated in the shape of naked human bodies of men, women, and children who are lying together in unity. The intensive use of colors in this painting is significant, as life is represented in various light colors, while death is veiled in black and dark purple. Moreover, Klimt uses crosses on death's robe to link to the symbol of Christian graves.

With the advancement of new art techniques in the 20th century, death received a different face wrapped in old symbols. In *Dada Death* (1918), the artist George Grosz put on a skeleton mask and walked through the streets of Berlin. Here death continued to possess the typical face of a skull, but at the same time death smokes a cigarette and walks between humans. In the classic movie *The Seventh Seal* (1957), directed by Ingmar Bergman, death is represented as an older man in a black robe with a white face. In this emotionless personification, death appears as almost benign. A young warrior is able to delay the end by making death play chess, but he cannot escape his fate. Ultimately, death wins and takes a whole group of people to the final dance of death, evoking the image of la danse macabre. *Meet Joe Black* (1998), directed by Martin Brest, is a contemporary film in which death is personified. The American actor Brad Pitt plays a handsome and charming personification of death who falls in love with the daughter of the man slated to die. Death is presented as a generous fellow and gives the old man more time to say farewell to family and loved ones, without revealing his true nature to the rest of the world. Though classical symbols such as the skull are still used in modern images, in modern depictions, death possesses a more flexible and adjustable nature and is open to negotiation. These depictions of death reflect the human desire to control death.

The Psychology of Personifications of Death

In psychological research death has been studied from different perspectives. Robert Kastenbaum and Ruth Aisenberg (1972) identified four categories in people's personification of death. They asked respondents to describe death as a person. From the answers the following four characters were identified: Macabre, Gentle Comforter, Gay Deceiver, and Automaton. The Macabre views death as a frightening figure, whereas Gentle Comforter is a calm and nonthreatening personification. The Gay Deceiver is an illustration of death as tricky and tempting, and the Automaton is death presented as an unemotional and mechanical entity. This study concluded that most respondents described death as an older male with a gentle character, with second and third identifications of death with a cold attitude and death as a grim, terrifying character, respectively. According to Kastenbaum and Aisenberg's study, if death had an age and gender he would be around 60 years old and male. Other

studies also revealed that personifications of death are related to gender, death anxiety, professional association with death (e.g., funeral directors), and belief in an afterlife. Recent studies focus on death personifications and adolescent risk behavior. Nowadays researchers use standardized instruments in measuring death personifications, such as the Adjective Check List, which consists of 300 person descriptions and is mainly used in personal and social psychology. The research on death personifications can bring us closer to understanding the relationship between humans and their experience of death. Throughout history people have tried to build an image of death by attaching human characteristics. Whether it is fear or fascination that motivates us to create a picture of death, it certainly will not stop in the near future.

Photography of the Dead

Many Christian societies used the photographic method to depict the dead. Whereas this practice may now appear unusual, it had been in fashion from the 19th century to the beginning of the 20th century all over the Christian world. Such a phenomenon raises two issues. The first is the necessity to understand the sense and the social uses of these pictures in the social context of the period. Second is the desire to understand the causes of the disappearance of this practice. Indeed, the refiguring of the family structures and the waning of the importance of religion in the Western societies had a great impact on this practice. This means that the photography of the dead makes sense in a particular social context in which people used it to face the reality of death, then perceived through Christian cosmological ideals. The following discussion presents the association between this form of human experience of death and the social context within which it occurred.

The first part of this entry addresses the recourse to the photographic method to represent the dead in different Christian countries. Then, the discussion focuses on the process of idealization of the dead. Indeed, during funerals the social group creates an idealized memory of the deceased fixed by the pictures. Fixing this idealized memory, these pictures serve three main functions: (1) to create family ancestors, (2) to perpetuate the family identity, and (3) to enhance the process of mourning. Lastly, the phenomena responsible for the disappearance of this practice are discussed in order to present a more global perspective on the association between the photography of the dead and the social context.

Postmortem Pictures as Representations of the Dead

In keeping with the tradition of representation of the dead—which involves recumbent effigies, postmortem depictions, and mortuary masks—the photographic method was used in the 19th century in order to depict the dead. This medium was initially used by painters as a model for the postmortem painted portraits, but photographs progressively became actual representations of the dead. Indeed, the photographic method had major advantages in that pictures were considered faithful reproductions of reality, were infinitely reproducible, and were affordable. Whereas the postmortem portraits were initially intended for the rich and public characters, the appearance of the photographic method allowed a complete democratization of this practice.

Postmortem pictures mainly consist of taking pictures of the deceased lying in state, or of the entire funeral, including the deceased lying in state, the mass, the procession, and the inhumation (see photos). Nevertheless, pictures are found in which dead children are represented in a state of sleep. Indeed, the parents who lost a young child but did not take a picture of him or her when living could, through this medium, still have such a memory in which the death does not appear so obvious.

As with other means of representing the dead, postmortem pictures are associated with Christian conceptions of death. They can be considered as an expression not only of the *ars moriendi* but also of the belief in resurrection. According to this belief, each individual is composed of a body and a soul which are separated after death but which are supposedly reunified after the Last Judgment. In this view the corpse represents strong meanings and the postmortem pictures make sense. Each picture is not only a representation of a deceased person but also a representation of an individual.

The correspondence between Christian conceptions of death and the postmortem pictures explains why these were generally accepted in Christian countries. During the 20th century, this practice was in use in Mexico, Peru, Argentina, the United States, and all over Europe, including in France, Spain, Italy, Denmark, Poland, Hungary, Bulgaria, and among Christian Ghanaians.

Used in different ways, the pictures could be distributed among the relatives, fixed on a brooch or on a pendant, kept in a special jewel-case, placed on the fireplace, hung up on the wall, or fixed on the grave. These pictures could also be placed in family albums among pictures of baptisms, communions, and weddings. In this case, they work as a family archive, which fixes the family history.

Postmortem Pictures as Idealized Images of the Deceased

It is important to consider the practice of postmortem pictures in a more global perspective. Whereas today people take pictures of everyday life, in the past pictures were taken during extraordinary and collective events, such as baptism, communions, weddings, and funerals. Thus, taking pictures solemnized and eternalized the major events of concern to the social group. These events were important because each displayed a change of status and refigured the social structure. Indeed, a baptism integrated an individual into the Christian community, the communion integrated teenagers among the adults, the wedding integrated a new family into the community of families, and the funeral integrated the deceased into the world of the dead. In other words, these events are representative rituals of passage and transition from one status to another.

During these events the social group behaves as if it were on stage and displays an idealized image of itself. Thus, photography as nonverbal text fixed this social ideal. When placed in family albums, the pictures work as archives telling the family and group story, as a storyboard may do, by figuring the major stages of the collective life.

The postmortem pictures are considered a part of this process. Indeed, according to Christians, death is not a rupture but a transition from one state to another. It is the last stage that ends the earthly life cycle. And, the funeral creates an idealized image of the deceased. The manner of dress, the quality of the coffin, and the quantity of mourners and of religious symbols ideally demonstrate one's social status and adherence to the group's social values.

Thus, the ritual and postmortem pictures cover three main dimensions: cosmological, social, and individual. Indeed, by creating a collective memory of the deceased, the social group reaffirms its unity weakened by the loss of one of its members, but it also reaffirms the continuity between the earthly and the life after death. This memory and this continuity are also means to face the distress caused by death. Thus, the deceased do not disappear but continue to live from beyond the grave. They are supposed to live closer to God and in the memory of the living. The fact that postmortem pictures cover cosmological, social, and individual dimensions leads us to attribute to them three major functions: ancestralization, family integration, and the trace.

The Functions of Postmortem Pictures

Ancestralization

An ancestor can be defined as a divinized dead person. In the case of family ancestors, families are involved in a system of allegiances. They have the duty to care for the memory of their ancestors and to satisfy their expectations by rituals, prayers, and the respect of taboos. An unhappy ancestor can cause damage to the living. Those who are living hold expectations of their ancestors as well. Indeed, if they encounter a problem, the living can ask the dead ancestor for help. As Jean Baudrillard states, dead and living are both involved in a process of symbolical exchange. In anthropology, a distinction is made between societies with a cult of ancestors (as in China, Madagascar, and some African countries) and societies with a cult of the dead (as in Western and Christian countries).

The case of Poland shows this distinction. Polish Christians think they can help the dead by praying for the raising of their soul, whereas the Christian dogma states that everyone is judged according to his or her acts. But Polish Christians also think they can expect help from the dead. In this perspective the dead are considered as ancestors in a Christian society.

In this context, postmortem pictures can be considered as representations of family ancestors. By expressing their adhesion to cosmological values with religious symbols and objects, the suggestion is that the deceased will join God and the Saints and will, from this affiliation, be more powerful.

Family Integration

Embodying the family social background and the social ideals, postmortem photographs function as an important identity reference for a family. Indeed, albums are generally consulted during family meetings and promote the transmission of family memory and identity. By expressing their allegiance to an ancestor, family members not only reaffirm their links but also their common identity. Simultaneously, the awareness of its social identity allows a family to preserve its position among the social group.

The Trace

The function of trace has psychological meaning. Indeed, postmortem pictures function as *transitional* objects, meaning that they support the transition between an external reality and an internal one. The process of mourning works in a similar way. First, mourners have to awake to the consciousness of an external reality—the death of somebody—and then internalize progressively the relation with the deceased. Thus, by showing the reality of death and by supporting the memory of the ancestors, postmortem pictures can be considered good media for the transition between the acceptance of the loss and the perpetuation of the internal relation with the deceased.

In contemporary experience postmortem pictures are less fashionable. Although still in use in countries such as Ghana, the Western countries have, since World War II, all but abandoned this practice. Secularization, urbanization, individualism, and professionalization of the funeral field are the major phenomena that account for this change. Indeed, secularization causes a distancing from religion and Christian conceptions of the corpse and of what happens after death. Simultaneously, urbanization implies new legislation based on public health concerns and intensifies the focus on individualism, and so religious and social networks of solidarity become diminished. The families in grief, who were previously supported by these networks, are also more isolated. This social isolation explains in part why families request funeral firms to organize the funeral. Thus, whereas the corpse was previously a ritual object, a critical component of the social and religious dimensions, the funeral now takes on a more profane characteristic managed by medical personnel and undertakers. As postmortem pictures made sense because the corpse was considered a sacred object, the corpse's involvement in a professional dimension explains the irrelevance of postmortem photos in modern societies.

Popular Culture and Images of Death

Western society is normally described as a death-denying culture; death is seldom discussed in an open, forthright manner. Rather, euphemisms for death and dying are employed, and the topic has been characterized as taboo or even pornographic by some observers. People also attach fearful meanings to death and dying. However, citizens simultaneously seem to have an almost fanatical attraction to death-related phenomena. Since people are generally insulated from personal experience with death and dying, they regularly seek information on these phenomena. For instance, images of death, dying, and the dead occupy a prominent place in popular culture and regularly appear in various entertainment and information media. Popular culture, which is a core part of collective existence, both reflects and influences death-related attitudes. Although thanatological themes have historically occupied an important place in Western popular culture, with the advent of new technologies such as the Internet and satellite television, cultural space is even more saturated with these death-related images.

Print Media

Thanatological themes play a major role in the printed media; books about war, crime, and mysteries have been exceptionally popular. However, with the advent of photojournalism, graphic images of death and dying are especially prominent in the print media. Stories about these topics, frequently accompanied by attention-grabbing headlines, often appear in newspapers. Yet, newspapers usually only portray particularly catastrophic, ghastly, and spectacular causes of death. One notable exception is the obituary, which often includes a photograph of the deceased individual.

Death-related images are also prominently featured in many popular news magazines such as *Time, Newsweek,* and *U.S. News & World Report.* Such publications often contain color photographs of the terrible devastation of events such as the September 11th attacks and Hurricane Katrina, as well as gruesome pictures of the victims of war and genocide. Perhaps the most extreme example of this phenomenon is the supermarket tabloids. These publications, with an estimated weekly readership of 50 million people, include articles about accidents, murders, and life-threatening celebrity health scares, as well as features about near-death experiences, ghosts, body disposition, and reincarnation.

Cinema and Television

Death and dying are also a very important part of many genres of cinema. Examples include movies about war, westerns, and dramas. Others include films about accidents, disasters, terrorism, and extinction level events (e.g., a meteor striking Earth). There have also been comedies featuring these topics, such as *Weekend at Bernie's* and *Dead Man on Campus.* Horror films have traditionally been, and continue to be, wildly popular with a significant segment of the population. These include movies about killers, monsters, and zombies, as well as thrillers. The "slasher films" of the 1980s such as *Halloween, Nightmare on Elm Street,* and *Friday the 13th* were exceptionally popular. The horror movie is experiencing a resurgence in recent years, as evidenced by the success of ultraviolent films such as *Saw* and *Hostel.*

Television viewing is an important aspect of the recreation and leisure activities of the masses. Death, dying, and the dead are prominent motifs in much of contemporary television. These are the central themes of many of the most highly rated prime-time television programs, including crime dramas (e.g., *CSI: Crime Scene Investigation* and *Law & Order*) and medical dramas (e.g., *House,*

Grey's Anatomy, and *ER*). These topics are also featured in a variety of other types of television programs. Examples include soap operas, mysteries, documentaries, children's cartoons, and reality shows. These topics are even a mainstay in religious television programming.

In contemporary society, news and entertainment are frequently combined into "infotainment." Televised news coverage has taken on a new, and even more influential, dimension because of the global reach of satellite broadcasting and 24-hour cable news outlets such as SkyNews, CNN, FOX News, and MSNBC. Accordingly, the news media plays an integral part in the transmission of knowledge and information to the general public in the new millennium. Contemporary televised news media are saturated with images of death, dying, and the dead. In times of tragedy, disaster, and crisis, people turn to media outlets for information and these traumatic events in turn become media events. For instance, the funeral of Princess Diana was seen by an estimated 2 billion people worldwide. In turn, the media assist in framing these events in ways that affect how people subsequently attach meaning to these events. Consequently, for many people, the media coverage of these situations becomes the reality, and critics express concern that it is becoming increasingly difficult to distinguish between the actual reality of a situation and the media portrayals of the reality of that situation.

Music

Death and dying have been pervasive themes in popular music as well. These motifs are especially common in contemporary forms of music, particularly rap and heavy metal. However, death-related imagery has become even more influential inasmuch as televised media have added an additional outlet for the dissemination of these thanatological images associated with this music. One prime illustration is the music videos that appear on television networks such as MTV, MTV2, and VH1. These music videos often feature scenes relating to homicide, disasters, accidents, illnesses, and afterlife concerns. In fact, one of the most popular music videos of all time, "November Rain," by Guns N' Roses features a funeral. Live musical performances that regularly appear on broadcast events such as *The Grammys* and the *MTV Video Music Awards* also feature songs with death-related themes. Examples would be performances of "Murder Was the Case" by Snoop Dogg (a song about homicide charges) and "Stan" by Eminem (a song about a murder-suicide). Arguably the most striking example of this was Elton John's performance of the song "Candle in the Wind '97" at the funeral of Diana, Princess of Wales. This ballad, which was among the best-selling and most successful songs of 1997, was an adapted version of the artist's musical tribute to deceased motion picture icon Marilyn Monroe.

Internet

The Internet revolutionized social life, and it now occupies an increasingly influential place in popular culture. As a medium for communication, the Internet transcends geographic, political, and social boundaries. Images and videos, even those taken by a mobile phone, can be instantly disseminated and viewed worldwide. One recent example is the video of the execution by hanging of Saddam Hussein. The Internet is fraught with thanatological content. For instance, there are a variety of virtual memorials to the deceased, and some individuals have blogged (including photographs) their battle against terminal illnesses such as cancer. However, some of this content is far more graphic in nature. One site, called "The World of Death," boasts a large collection of death photographs, including crime scenes, accidents, suicides, executions, and beheadings. There are dozens of similar websites. Some of this death-related content is political and controversial. For instance, members of jihadist terrorist groups post videos of their attacks and beheading of hostages, as well as videos of the last public statements of suicide bombers. The death-related content of the Internet even assumes some configurations that are humorous in a convoluted fashion, such as celebrity dead pools and web pages dedicated to dead celebrity jokes.

Dead Celebrities

Images of dead celebrities occupy a special place in postmodern cultural space. The notoriety of some of these individuals has assumed a pseudoreligious

dimension in contemporary society, sometimes referred to as "symbolic immortality" (i.e., a person's meaning lives on after she or he has died). Examples include Elvis Presley, James Dean, Marilyn Monroe, Mother Theresa, Bruce Lee, Tupac Shakur, Jim Morrison, Ernesto "Che" Guevara, and Kurt Cobain. However, the best illustration of this phenomenon in recent years is the case of Princess Diana. Following her tragic death she was memorialized in a number of ways including songs, videos, web pages, stuffed animals, books, towels, ashtrays, and stamps, to mention but a few. In essence, through images in popular culture, deceased public figures such as Princess Diana continue to exist in the minds of the living.

The Death and Dying Paradox

Sociologists note that a culture's death-related practices and beliefs are linked to the social organization of society. On the one hand, contemporary society is characterized as a culture that systematically denies death and dying. On the other hand, there is an obsessive fascination with thanatological topics that is manifested in the presentation and consumption of death-related images in popular culture. These images are essentially cultural products that simultaneously reflect and influence attitudes about death, dying, and the dead. One possible explanation for this apparent paradox may be that the United States may not be the death-denying society as some analysts allege. However, the fascination with death-related phenomena could also be interpreted as a manifestation of death denial. The saturation of cultural space with thanatological images may desensitize people and thus reduce viewer anxiety about death and dying. In popular culture, death-related phenomena may be presented as fascinating, exciting, entertaining, and even humorous. The sensational images of accidental, violent, and otherwise gruesome deaths may even result in a convoluted type of voyeuristic pleasure for some people, such as the "accident watchers" in the population. Through the reconceptualization of death and dying, the traumatic nature of these events can be socially neutralized. The appreciation of these images also necessitates some degree of detachment, thus further insulating the individual from such death-related anxieties. Even though we are saturated with these images, we rarely view actual corpses.

These images of death, dying, and the dead have been, and most likely will continue to be, the source of a great deal of social controversy. Advocacy groups, as well as medical and mental health professionals, have criticized the amount of violence in television and movies. There are concerns that this may desensitize young people to death and dying, as well as possibly serving as the catalyst for real-life violence. Similarly, popular music, especially "gangsta rap" and "heavy metal," are also criticized. Because these cultural artifacts sometimes include eschatological images of demons and hell, this has drawn the ire of religious and social conservatives. Video games have also been condemned for the portrayal of violent death. With the increasing popularity of new media such as the Internet, the presentation of graphic images of death and dying with continue, if not increase, in frequency. The attendant social controversy is destined to continue.

Pornography, Portrayals of Death in

Portrayals of death in pornography depict the juxtaposition of sexuality with death. Although much literature includes the topic, the representation of death in pornography is relatively rare, as pornography constitutes intention on the part of the pornographer to induce sexual arousal. The understanding of portrayals of death in pornography and its definition are related to whether the material in question is appealing to prurient interests. This entry addresses these issues within the context of changing social mores and the evolving definition of pornography as it portrays death.

The Context of Pornography

Some contemporary media link death with pornography but as separate and distinct elements. Some Internet websites, for example, provide short film footage and claim extremity and perversion. Content does not reveal death and pornography evidenced in the same films. Rather, films of death and films of pornographic representations are offered as distinct film foci. A portrayal of death in pornography may be a fictionalized representation or a depiction of an actual occurrence of death. In the case of pornography, either representation constitutes a portrayal of death.

Arousal from pornography may be physical or psychic. Thus, to arouse sexually does not necessarily require a physiological arousal and may be entirely psychically focused. Alternatively, the intention to stimulate sexually may be unsuccessful in some individuals. But if the text is defined as pornographic in that it is designed and created with the intention to sexually stimulate the observer, the failure to sexually stimulate in some observers does not change the initial intent of the pornographic text.

Pornography is designed to stimulate the mind into considering a possible sexual activity or relationship. Portrayals of death in pornography may personify what Sigmund Freud referred to as the drive of *thanatos*, the "death" drive. Freud postulated that there were two distinct forces in the human psyche: libido, or the life drive, and thanatos, the death drive. Both instinctual drives are theoretically antagonistic to each other. Freud observed regular though infrequent variation away from what he assumed was a "normal"' sex aim: namely, reproductive heterosexual dyadic coitus in humans. Such variation may include gender or object variants. Other analysts have suggested that Freud's concept of sexual libido may be channeled toward any object, thereby rendering obsolete the idea of a "normal" object onto which libidinal energy attaches. The implications move from a "normal" singular focus of libido within a sexualized arena to a diversity of libidinal objects, situations, spaces, and relations.

Pornography as a text is intended to induce sexual stimulation. If one keeps in mind the flexibility of libidinal object, it may be addressed using a variety of subjects. In this regard, the possibility of the eroticization of death becomes understandable as one possibility.

Attitudes and actions in response to death are culturally specific and significant taboos surrounding death and sexuality in most cultures. Pornography may be received as a text that is intended to be sexually stimulating, or it may be read as a vehicle to instruct the novice in the realm of sexuality. For this reason pornography is often regarded as dangerous for those involved in the production of pornography as well as for the consumer.

Some feminist thinkers raise concerns with pornography that depicts women violated in violent situations, as objectified and adjunct/accommodating/subservient to male sexuality and sexual satisfaction. Much of the feminist critique has centered on the notion that women are degraded in the sexualized heterosexual depictions. Sadomasochistic representations of pornography, which frequently include the death of the submissive female, also have generated concern among feminist analysts. Such critical arguments are based on structural power imbalances made obvious in sadomasochistic heterosexual pornography, which instructs men, the predominant users of pornography, to maintain power imbalances between the sexes.

The Marquis de Sade penned a number of texts that included portrayals of death within the pornographic content. Writing in the mid to late 18th century, de Sade's texts were designed to excite sexually and were received as such. His writings outraged the political power of the time but were eagerly received by the general public. De Sade's depiction of death is resultant from overt acts of murder as well as the

engagement of activities that inadvertently end in death, though these outcomes occur through deliberate engagement in sexual activities.

De Sade's *120 Days of Sodom* is a pornographic work that details a clandestine location wherein "friends" and "libertines" engage in largely nonconsensual sex. De Sade's fictional pornographic accounts include many descriptions of mutilation resulting in death, and he outlines a variety of sexualized acts that induce horror and revulsion. The metaphor of a clandestine location in de Sade's text may reflect the intellectually clandestine location of the ideas presented, ideas that may be understood as part of Western sexuality. The sexualized universe represented within de Sade's work gestures toward a disordered portrayal of human interaction that stands in marked contrast with the "rational," ordered universe of the Enlightenment.

Posthumous Reproduction

In Western culture, the practice of creating a likeness of an individual's face and/or body after death through media such as photography, drawing, painting, wax, or plaster can be traced back to at least classical antiquity. These images of ordinary individuals as well as the rich and powerful had a variety of overlapping functions. They reminded the living of the brevity of life, provided a record of death, preserved the features for posterity, and assisted in the rituals of grief and mourning. Although the practice waned considerably in the early decades of the 20th century, it has revived in recent years.

The "death mask" is perhaps the oldest method of preserving the features of the deceased. An exact copy of the face was made by covering it with plaster or wax and allowing it to harden thus creating a mold. A "mask" or bust could then be prepared from this mold. In Roman culture wax masks, called *imagines,* made from death masks of the deceased were displayed in the home and used in funeral rituals. The masks were important particularly for the patrician classes as they established the lineage of an individual, separating him from the lower classes below and those of wealth and power with less established ancestry. When a member of the family died, hired actors would wear the masks and march in the funeral procession, reviving not only the likenesses of the ancestor but also reviving his virtues as well.

The use of death masks continued into the medieval and Renaissance eras during which time they were also used as aids for sculptors creating tomb effigies for the aristocracy and for the lifelike funeral effigies for the lying-in-state of monarchs and other national figures. The best preserved examples of these effigies are in Westminster Abbey. The bodies of these figures were often fashioned of wood, or leather stuffed with hay, with faces and hands made from plaster, wood, or wax. The features were painted or tinted with added facial hair and eyelashes to appear as lifelike as possible. Often dressed in the deceased's own clothing, the effigies provided not only a facial likeness of the dead, but a reproduction of the entire body around which appropriate mourning rituals could be performed as the effigy would not suffer the physical corruption of the deceased's actual body.

Death masks continued to be made well into the 19th century affording posterity with an opportunity to look into the faces of the famous, such as Walt Whitman and Frederick Chopin, years after

their deaths. The masks could also provide more ordinary families with comfort and solace in their grief. Although the practice of making death masks seems to have waned in the early 20th century, it has made a resurgence in recent years as British artist Nick Reynolds and groups such as the Association of Lifecasters International in Summit, New Jersey, continue to receive requests for the masks.

In addition to the death mask, painting and drawing were also popular methods to preserve the likeness of the recently deceased and examples survive from at least the 15th century. These images served a variety of functions. Paintings such as John Souch's *Sir Thomas Aston at the Deathbed of His Wife* (1635) record not only a specific death but also depict the family's mourning, demonstrating their love and participation within accepted societal codes of grief and mourning. Drawings not only recorded the physical features of the deceased for the family, but they also could be used as a model from which the artist would fashion a painting showing the deceased as if alive, such as Ralph E. W. Earle's portrait of Sarah Louise Spence, circa 1833. Although Earle clearly depicts Sarah looking out at the viewer, he communicates the young girl's true state by depicting her holding a rose cast downward, a symbol of a young life cut short.

When photography was invented in the late 1830s it, too, was employed as another medium in which to create postmortem images. Because it also quickly became a relatively inexpensive way to capture a likeness, photography made it easier for families of almost every class to have a last image of their loved one. Although most postmortem photographs are of children, there are a significant number imaging adults as well, and photographs survive from almost every social stratum from the British monarchy to working-class families in America. Children were often photographed being held by parents and siblings or tucked into their beds, their limbs arranged to mimic sleep. The tension between the semblances of life and death were further obscured as many families requested the child's eyes be opened and the body propped up to appear sitting and or holding a favorite toy. While these images often appear gruesome to modern viewers, there is numerous testimony in 19th-century diaries and letters attesting to the great solace and comfort these images provided for the grief-stricken families. More recently, collectors have become fascinated with postmortem photographs, and the numerous websites on the Internet and texts written about them have made the practice more widely known to the general public. While the actual practice of taking postmortem images, like that of death mask, also waned in the early 20th century, postmortem photography has more recently been adopted for use in hospitals to assist families through the grief of a stillborn child.

POSTSELF

The postself is who one is in the minds of others after you are dead. It is one's postmortem reputation; it is how one is remembered; it is one's place in human history. Many individuals, while they are living, have a considerable investment in their postself reputation. The concept of the postself casts a rather wide net, dealing as it does, by implication at least, with the issues of afterlife and hereafter, life-after-death heaven, reunion, resurrection, angels, saints, and god. On the other hand, it is limited to the thoughts and aspirations of living persons, living in a here-and-now world.

For some, the positive postself can be an important goal of life. To have one's memory live on or

to have a participative future in the world yet to come can be of vital importance. The desire may not be legendary, like Mozart or Lincoln, but rather an extension beyond the date on one's tombstone.

There are various ways in which an individual can continue to live on after death. First, and perhaps most importantly, in the memories of others. In life one can make his or her actions count or, just by being, capture the interest and concern of others. Second, there is active stimulation of others through one's works, such as art, music, and writings. A third means is through the use of a legal document, such as a will or directive, in which a living person seeks to control the behavior and welfare of others through what is essentially a system of punishments and rewards.

Yet a fourth means through which one can continue to live on is through suicide notes. Such notes represent a crucial extension of the self beyond death, and these documents often are replete with absolutions, accusations, and exhortations. The suicide note can be a powerful, impactful document through which the postself lives on.

The fifth way the postself is guaranteed is within the body of another person through organ transplantation, either from a living donor or from a cadaver. Thus, one's postself is achieved through the use of body organs or perhaps body parts.

The postself is assured yet a sixth way in the genes of one's children. Indeed, genetics assures that there is biological immortality. Genetic inheritance lives. DNA seems almost infinite. There is an immortal chain of living things. Philosophers write about "generativity," that egotistical hope that one's children and grandchildren might carry on one's work after death puts an end to one's efforts, that they will supply biological escape from death. One becomes a part of the whole stream of human existence with an overflow into an unknown future.

Finally, philosophically, one may achieve a postself through the cosmos. One must try to live as if one is immortal and as if society is eternal, knowing that both assumptions are false. But each must be accepted on faith if one is to believe one will continue to live through the postself.

To cease as though one had never been, to exit life with no hope of living on in the memory of another, to be expunged from history's record. For some individuals this may be a fate far worse than death. Only a feral child or a deeply autistic person might not be capable of conceptualizing a postself.

If one is fortunate enough to live a long life, his or her heart muscles will beat several million times a day. Little more in life is certain. That is why living thoughts of oneself after death can be psychologically important. Herman Melville, arguably one of America's greatest novelist, was right on the mark when he wrote to his friend Nathaniel Hawthorne (in June 1851) that he would be unknown in his own century but that he wrote for a posthumous glory to come. Melville's investment was in his postself.

Pre-Need Arrangements

Pre-need funeral arrangements are the practice of organizing and paying for funerals prior to death, and usually while the purchaser is in (relatively) good health. A term used interchangeably with *pre-pay funerals*, *pre-need arrangements* are part of a wider expansion of consumer choice and individual empowerment in bereavement services. Comparable practice can be found in the development of living wills and patient-centered end-of-life decision making. As a source of income generation, they also form part of a broader commercialization and commodification of the funeral directing industry, whereby funeral providers have become increasingly entrepreneurial and consumer oriented.

Profiling Pre-Need Planning

Not much is known about those who purchase pre-need plans, but research evidence suggests that those who purchase pre-need arrangements tend to be older, more educated, and more religious than

those who do not. It was estimated in 2003 that over a third of all American funerals had been paid for, at least in part, in advance.

While there remains much to be learned about the uptake of pre-need arrangements, much more is known about the business features of pre-need arrangements. In their summary of pre-need arrangements in 1995, Mercedes Bern-Klug, Stanley DeViney, and David Ekerdt found that the cost of pre-need arrangement in the United States ranged enormously, between $195 and $14,000. Such disparity in cost they attributed to the varying fees charged for body disposition—burial, in particular, tends to be more costly than cremation. This range of charges for pre-need arrangements indicates that they are a profitable source of income for plan providers.

As a tangible example of a growing commercialization of death, there are concerns about how pre-need arrangements are regulated and monitored, and the extent to which funeral guarantees are upheld. On the other hand, however, proponents of pre-need argue that they offer choice and flexibility, and enable the individual to leave specific instructions as to what they want to happen after they have died.

Often marketed as providing "peace of mind" in offering the consumer reassurance that provision will be made for their funeral costs and that their wishes will be adhered to, the origins of pre-need arrangements can be found in formal state funerals, in which the funeral was arranged, usually with the agreement of the figurehead, prior to his or her death. The idea that a funeral is paid for before the individual has died also bears similarities to 19th-century burial clubs in North America and the United Kingdom, where individuals paid a weekly fee to cover the cost of their funeral and burial. Pre-need arrangements became popular toward the end of the 20th century as large conglomerate companies began purchasing and operating funeral director chains, and recognized that pre-need arrangement plans not only were feasible in their provision but also were an ongoing and reliable source of income.

Pre-Need Option Payment Plans

According to the National Funeral Directors Association in the United States, there are three ways of arranging and paying for a pre-need funeral plan. First is the option of paying into a trust fund, which is usually arranged through a funeral director, a cemetery, or a private company. In this option, a percentage of the money invested is set aside for the cost of the funeral itself and the remainder becomes available for the use of the trustee at his or her discretion. The second option for a pre-need arrangement is available through insurance companies in the form of an insurance policy. These policies cover the cost of the funeral in the event of the policyholder's death. The third option for pre-need is setting up a savings fund for the explicit purpose of paying for a funeral, which is also referred to as an account payable on death, or POD.

The Funeral Industry and Pre-Need Planning

Pre-need arrangements were initially met with an initial resistance from funeral directors. This was because they thought that, in their experience, people were prone to purchasing more in emotionally charged situations. Arranging and paying for funerals in pre-need conditions was, therefore, seen as undesirable as the customer would most likely be calmer and purchase less. These early concerns reflect the continuing tension between providing an empathetic bereavement service and making a profit. Nevertheless, funeral directors' fears were alleviated by two reasons: First, pre-need arrangements have consistently sold well among pre-need populations and have been adopted as a part of the ever-expanding insurance industry. Second, the bereaved are able to "top up" funerals after the death of a pre-need policyholder. Conversely, this capacity for the bereaved to alter the arrangements made by the deceased policyholder suggest that some, if not all, of the planholder's arrangements can be overridden after he or she has died—an issue of great unease for those concerned about how pre-need arrangements are sold and regulated.

Common Features of Pre-Need Option Plans

In general, there are common themes throughout most plans, unless the pre-need arrangement is simply the provision of funds with no accompanying

explicit requests. Most plans cover advice for the bereaved on the certification and registration of a death, the cost of fees payable to doctors and clergy, care of the body prior to disposition, and the charges for the disposal of the body. Beyond these, the consumer also has a wide range of choices to make with regard to the level of coverage the plan provides and the format, structure, and content of the funeral service. The pre-plan customer can choose the available merchandise, which includes the casket, outer burial container (vault or grave liner), urn, register books, acknowledgment cards, memorial flowers, and clothing facilities. They can also choose how their memorial service is conducted; the vehicles for use in the service, such as a hearse and/or limousine; the cemetery plot and/or other charges; the equipment and staff at the graveside; and the forwarding and receiving of remains. Customers have the option to be very specific in their requests, such as "a mahogany casket with the Last Supper on the upper inside lid," or provide more general requirements, such as a "medium-range coffin/casket."

Supporters of pre-need arrangements point to how choosing from this selection of options when in a calm state of mind ensures that individuals can truly exercise their freedom of choice and ensure that they get what they desire. In addition, individuals have the time and opportunity to shop around for their pre-need plan of choice, enabling them to make an informed decision. Proponents of pre-need also point to how arranging and paying for a funeral prior to death can take pressure off the bereaved in having to make decisions and ensure that there are funds available for the funeral and bodily disposition.

Pre-Need Consumer Advocacy

In the United Kingdom, the Natural Death Centre actively promotes pre-need arrangements as part of a practical, hands-on approach to death and dying. As an option that enables the individual to decide the conduct of activity after their death, the Natural Death Centre contends that pre-need arrangements offer the individual a degree of control over how their body is treated, how they are disposed of, how they are mourned, and how they are memorialized. Pre-need plans can thus encourage individuals to contemplate their mortal condition. As a result, they are viewed and promoted as part of a healthy and responsible attitude toward death. In this vein, pre-need arrangements also suggest there is a contemporary openness about death, one which sharply contrasts with the popular view of death being taboo or denied.

Reservations have been expressed, however, as to the commercial features of pre-need arrangements. Aggressive marketing of pre-need plans, and the possible exploitation of vulnerable populations, such as the elderly or chronically ill, is a concern. It was estimated by the American Association of Retired Persons in 1999 that 43% of Americans age 50 and older had been solicited by pre-need plan providers.

Further concerns have arisen about how pre-need arrangements are upheld. Sometimes the bereaved are able to "top up" the funeral after the policyholder has died. Not only does this suggest that the bereaved can override the deceased's wishes and the policyholder's requests may not be guaranteed by the plan provider, it also indicates that there are possible loopholes in providers being able to charge more in the event of the policyholder's death. Indeed, if insufficient funds were set aside for the funeral, then the provider may well *have* to ask for more. Thus, consumers need assurances that enough money will be available to cover the funeral and disposition costs in the event of their death. The pre-plan policyholder also needs to be assured of what happens in the event that the provider is no longer in business when they do eventually die.

Shopping for the Right Pre-Need Plan

When shopping for a pre-need plan, customers need to consider a range of issues, particularly the way the policy is guaranteed. Customers also need to consider what happens to the policy, should they move, and the security of the money they invest in the scheme. They need to be aware of any refund policy that exists with the plan or how—if at all—they may make alterations to their specified choices. Moreover, policyholders must inform someone of the existence and location of their plan, as it is not unheard of that the next of kin are unaware of a pre-need arrangement—or cannot find it—and arrange the funeral themselves. Finding a plan after a funeral has taken place may cause a great deal of distress for the bereaved.

Framing all of these concerns is one of the key issues surrounding pre-need arrangements: the monitoring of providers. In the United States, the National Directors Funeral Association has written a bill of rights for funeral preplanning; in the United Kingdom approximately 90% of providers are monitored by the Funeral Planning Authority and their code of practice. However, both of these documents are voluntary agreements and offer little statutory protection. With little recourse, consumers therefore need to be fully briefed and aware of the consequences of taking out a pre-need plan. If they are in a vulnerable position, such as being recently bereaved themselves, customers may not be able to make a fully informed decision—which is when concerns about aggressive marketing can particularly arise.

Yet, despite these wide-ranging and legitimate concerns over the regulation of pre-need funeral arrangements and the possible exploitation of vulnerable populations, it is important to recognize the value of pre-need arrangements for those who wish to organize their own funeral. Much like living wills and advance directives, pre-need arrangements offer individuals the opportunity to decide what happens at their funerals and to delimit how much is spent. Nonetheless, to ensure these wishes are adhered to, and in a growing climate of litigation, pre-need plan providers are required to supply clear and concise terms and conditions, and there is a need for coherent and consistent regulation of all providers.

Prison Deaths

Prison deaths remain one of the most poorly researched and documented areas in the social sciences. In no small part this is due to the "total institution" nature of prison facilities and their staffs and the concomitant secrecy that surrounds any death in that environment. Also, there has long been a tendency to use a narrow range of medical categories to define prison deaths; this narrow range of categories serves to obscure the actual causes in many cases. But prison deaths should include all cases wherein an inmate dies, regardless of the location or cause of death. In addition, terminally ill prisoners who are released as a gesture of mercy (or economy) should be included, as well as escapee prisoners who have died. In general, prison deaths include those due to homicide, suicide, and natural causes.

The difficulty of acquiring useful data on prison deaths is considerable under the best of circumstances, and once outside the economically and politically developed countries the problem becomes almost insurmountable. Considerable efforts have been made in recent years, especially by the United Nations, to fill in the blanks, but many gaps remain.

General Considerations

As a general rule, nations that are high-income or at least have significant elements of functional democracy are open in the reporting of prison deaths. Such nations have experienced a decrease in the number of deaths related to suicide and homicide but report an overall increase in prison deaths as a result of an aging prison population. This latter finding reflects the demographic trend of aging found in the larger population.

A common finding is that mortality rates in prison (all cases) are generally lower than those found in the general population. In the United States between 2001 and 2004, for example, the annual prison mortality rate of 250 per 100,000 was 19% lower than the mortality rate in the American population. The vast majority of prison deaths in the United States are due to suicide, homicide, and consequences of an aging population. In the period 2001 to 2004, inmates age 45 and older made up only 14% of the American prison population but accounted for 67% of all prison deaths. Chronic diseases such as heart disease (27%), cancer (23%), and liver disease (10%) accounted for most of the mortality among this older group of inmates. Many prison systems have begun to adapt to an aging inmate population by providing hospice for inmates who are terminally ill. The substantial drop in rates of suicide and homicide in the United States between 1980 and 2003 is noteworthy: The rate of prison suicides fell by 64%, and the rate of prison homicides fell by 93%.

In Canada, while the general tendency has been a decrease in suicide and homicide and an increase in mortality due to aging, there was one notable exception. In the late 1990s, the prison mortality rate for provincial institutions was 211 per 100,000 people, well below that of the general population. In the federal institutions, however, suicide was elevated and helped produce a mortality rate of 421 per 100,000, which was well above that of the general population of Canada. Much of the rise was due to the practice in Canada for inmates with longer sentences to be sent to the federal rather than the provincial institutions, a practice that led to elevated levels of suicide. In England and Wales, suicide and homicide prison deaths have also gradually declined. Between 2004 and 2005, for example, suicide deaths fell by 14%. In Australia, prison deaths have generally declined or remained stable, with one notable exception. Between 1980 and 1997, Australian prisons experienced an increase in suicide, which by 1997 came to account for 42% of all prison deaths. Efforts since that time have served to reverse this trend.

In Russia, which has the second largest prison population only to the United States, a dramatic increase in prison deaths caused by drug addiction took place during the 1990s. Between 1996 and 2003, the general Russia population experienced a ninefold increase in prison addiction deaths, and the prison system was no exception. However, recent changes in Russian law, with more emphasis placed on treatment rather than incarceration, should ease the rise of prison deaths due to drugs.

In Latin America, a basic problem that contributes to prison deaths is the widespread policy of incarcerating untried persons for long periods of time. In Argentina, for example, fully 50% of the 60,000 prison inmates have not been tried, but are confined to police lockups. The same situation exists in Columbia. In fact, lengthy incarceration of untried persons in Latin America is a general pattern and reflects the economic and political situation in those areas.

On the other hand, India has one of the lowest crime rates in the world. The major issue of prison deaths in that country is dehydration due to excessive heat. Prison deaths and crime are low in that nation.

Diseases and Related Matters

For many nations, an increase in prison deaths has been due to infectious diseases, especially AIDS. Many of the affected nations are also lacking in transparency in reporting such deaths. Despite these difficulties, there are sufficient data available to reveal the increase in prison deaths from infectious diseases, and in some cases the increases are large and the level of mortality high.

Sub-Saharan Africa has long been considered the epicenter of the AIDS epidemic. Prison populations in those areas tend to reflect the trends of the general population. South Africa is one of the few developing nations to provide fairly extensive statistical data about prison deaths in general and disease-related deaths in particular.

Since 1996, the number of prison deaths in South Africa increased by 584%, of which 90% to 95% were AIDS-related. It is estimated that about 42% of the prison inmates in South Africa are HIV-positive. Environmental conditions in South African prisons make the problem much worse. Overcrowding is rampant, and several prisons do not have running water. A judicial review recently pointed out that most prisons in that country do not abide by the South African law that requires testing of all new inmates for infectious diseases. As a consequence, life expectancy is lower and mortality

rates much higher for prison inmates in South Africa than is the case in the general population.

HIV/AIDS is increasing in other African prison systems as well. In Namibia, for example, the number of prison deaths due to AIDS has been on the rise in recent years, and about 60% of all prison deaths are AIDS-related. In Kenya, officials report that HIV/AIDS causes some 10 to 15 prison staff deaths monthly.

In Russia, although HIV/AIDS is also a problem, a much larger and more dangerous trend in prison deaths has been the spread of tuberculosis, including multidrug-resistant strains that were first detected in 1991 and have since spread rapidly inside the Russian prison system and far beyond. The rate of tuberculosis infection inside the Russian prisons is 17 times higher than that of the general population, and the number of prison deaths is 8 times higher than that of the general population. By 1999, these rates had increased to 58 times and 28 times, respectively. Indeed, it can be said that the Russian prison system has become the epicenter of a tuberculosis epidemic that has spread far beyond its prisons. Between 1990 and 2006, the tuberculosis rate in Russia had tripled (to 1 person per 1,000) and was 15 times higher than that in the United States. About 10% of Russian inmates have active tuberculosis.

Even more alarming has been the rapid increase of multidrug-resistant tuberculosis strains, which now constitute approximately 30% of all active tuberculosis cases in that country. In addition, HIV-positive inmates are far more likely to carry the multidrug-resistant strains, which serves to elevate prison deaths even more. The annual release of tens of thousands of prison inmates has made the Russian prison system the main source of rapidly spreading multidrug-resistant strains of tuberculosis.

It is reported that within the Indonesian prison system, some 72% of all prison deaths are due to infectious diseases. A lack of funds and overcrowded prisons make the situation even worse.

In contrast, in the United States AIDS deaths in prisons are decreasing. In 1995, a peak of 1,010 inmates died from AIDS in the United States; by 1999, this number had decreased to 242 inmates. But while AIDS-related deaths are down in U.S. prisons, HIV infection rates are on the increase. Although the rate of HIV infection increased only 6% for the general population between 1995 and 1999, the corresponding rate for prison inmates was 19%.

Political Oppression

The most secretive type of prison deaths are consequences of political activities by the state, either through direct action or through neglect. But it is virtually impossible to gain insights based on an accurate count of such prison deaths; most of the evidence is indirect and often contradictory. In all too many cases, some governments go to great lengths to hide such prison deaths in order to minimize public criticism.

Latin American and Caribbean prisons house over half a million inmates, usually under unsanitary and overcrowded conditions and with staffs that are rarely trained and generally corrupt. As a result, riots, gang wars, and staff assaults create many prison deaths in such countries, but few are openly reported. In Brazil, for example, Carandiru Prison experienced a riot in 1992 in which 111 inmates were killed. On May 29, 1998, another 22 inmates were killed in a gang war inside the São José Prison. Scores of inmates die annually from inmate-on-inmate abuse. One unintended consequence of widespread violence in Brazil's prisons has been to produce more highly organized and more formidable gangs. In Brazil, prison gangs have become the main opposition party to prison abuse.

China's prison system has been used by the state to systematically eliminate its enemies, real or imagined. In recent years the main focus of Chinese wrath has been directed against the Fulan Gong (also known as the Fulan Dafa). In 2004 alone, more than 140 Fulan Gong members died in custody. Between 1999 and 2001, government officials inside China confirmed the deaths in custody of well over 1,600 members of Fulan Gong. As hundreds of thousands have been detained by the state, the prison death toll is almost certainly much higher than officially stated.

Tibetans, including many monks, have also been the victims of death while in Chinese custody. Again, the figures are difficult to obtain, but some information is reported. It was officially reported that on June 7, 1988, five Tibetan nuns died while in custody.

Similar levels of prison deaths due to oppression have been noted in other countries. In Uzbekistan, for example, state violence inside prisons is directed at Muslims who attempt to practice their religion outside state controls. In Georgia, the state confirmed 24 deaths in custody in the year 2006 alone. In Turkey, inmates are routinely killed by military units sent to quell a disturbance of one kind or another. Kenya routinely tortures inmates to death.

In sum, for countries that are fairly wealthy and even those with some form of democracy, the unmistakable trend in prison deaths has been downward. One exception to this trend is an increase in prison deaths due to aging. For many countries, the unmistakable trend in prison deaths due to infectious disease has been up and, in some cases, dramatically so. For many other countries, because reliable data are so difficult to acquire, the trend in prison deaths due to various types of oppression has been unknown. More transparency in these nations will serve to drive these types of prison deaths down.

Prolonged Grief Disorder

Because loss is endemic to human life, so too is grief, defined as the psychological response to the loss of another in all of its emotional, cognitive, and behavioral aspects. Fortunately, as research shows, most people ultimately adapt well to bereavement, typically regaining their psychological equilibrium and moving on with life after some weeks or months of acute mourning, although they frequently will continue to miss their loved one for a considerably longer period of time. However, many studies also identify a subset of 10% to 15% of the bereaved for whom grief is both intense and chronic, persisting at disruptive levels for many months or years. This condition, termed *complicated grief* or (more recently) *prolonged grief disorder,* is one whose coherence, correlates, and consequences have received increasing scrutiny over the past decade in both psychiatric and psychological literatures.

As articulated most clearly by Prigerson and her collaborators, the diagnosis of this form of debilitating and intractable grieving is both more clinically precise than the vague and sometimes unsubstantiated depictions of "pathological" grief that have long populated professional discourse and better anchored in progressive programs of research. As it is presently being proposed as an officially recognized psychiatric disorder, the diagnosis applies to patterns of bereavement adaptation marked by persistent inability to function in work, family, or social roles over a period of at least 6 months, in the presence of chronic and intense yearning or longing for the deceased, and several associated symptoms of inability to accept the death, trouble trusting others, disruptive bitterness and anger, uneasiness about "moving on" with life, numbness and detachment, agitation, and a corrosive sense of meaninglessness regarding one's life in the present or future. It is thus conceptualized as a form of pervasive and profound separation distress following a sundered attachment, one that deprives the survivor of a secure base for

exploring the world as well as a safe haven from its storms and challenges, while also increasing the risk of severe and even life-threatening psychological and medical disorders.

Predictors of Prolonged Grief Disorder

Several factors predispose people to prolonged grief disorder following major loss. These include such childhood experiences as a history of early parental death or divorce. Likewise, later experiences in adulthood can also increase the risk of chronic and profound grief, including loss of a first-degree relative, such as a parent, partner, sibling, or child; sudden, unanticipated, or violent death of a loved one; and high levels of dependency on the other for a sense of personal well-being. Several of these factors suggest the role of attachment insecurity in increasing a person's vulnerability to complicated bereavement, as earlier experiences leave some people with anxieties about abandonment by others or a sense of insufficiency in meeting life's challenges on their own. In such cases, later losses of a loved one through death can trigger these vulnerabilities, provoking intense and extended separation anxiety that interferes with their post-loss adaptation.

Outcomes of Chronic Grief

In addition to the significant psychological suffering required for diagnosis, symptoms of prolonged grief disorder, when present to a marked degree 6 to 12 months or longer after the death, are associated with a broad range of functional impairments, such as poor work performance or trouble meeting family responsibilities as well as overall reductions in quality of life. Perhaps of greater concern, they are also associated with several specific health risks, including sleep disruption, substance abuse, compromised immune function, hypertension, heart failure, cancer, and suicide. It therefore is not surprising that bereaved persons who struggle with prolonged grief report higher utilization of medical services and more frequent hospitalization than people with similar losses whose grief is less profound and extended, and that these effects have been observed for as long as 4 to 9 years after the death. The fact that these negative outcomes emerge even when levels of depression and anxiety are taken into account argue for the uniqueness of a prolonged grief diagnosis and caution against considering bereavement complications simply as a relabeling of conventional psychiatric conditions.

Distinctiveness of Prolonged Grief Disorder

Evidence indicates that bereaved people can respond to their loss in a variety of ways that range from resilience or even personal growth, on the one extreme, to life-limiting or life-threatening adaptations on the other. In the latter category, loss can trigger major depression in perhaps 10% of those who suffer it, and post-traumatic stress disorder (PTSD) in still others. However, these conditions are importantly different in some respects from prolonged grief disorder as defined here. For example, whereas depression is characterized by a predominant emotional state of sadness and anhedonia (the inability to experience pleasure) and PTSD is associated with predominant emotions of fear and panic, prolonged grief is defined by profound separation distress and acute loneliness. Furthermore, cognitive themes in depression and PTSD focus on a sense of the self as unlovable or a failure, in the first instance, or as weak and vulnerable in the second. In contrast, in prolonged grief the bereaved person's central preoccupation is with the self as alone in the world, even in the presence of caring others. Brain imaging studies also distinguish between depression and acute grief, with the former suppressing activity in those brain centers responsible for processing personal memories, whereas the latter actually produces heightened activation of these same structures. This corresponds to reports of impaired concentration and recall among depressed people, in contrast to the experience of intensely grieving people, who are often drawn to obsessive review of memories of their loved one to an extent that it is difficult to orient to a changed future. It is therefore important to recognize that any given bereaved individual can struggle with depression, posttraumatic stress, prolonged grief, or any combination of these conditions, but also to bear in mind that they should not be considered equivalent in their phenomenology (how they are experienced) or neurophysiology. Evidence strongly indicates, however, that a diagnosis of prolonged grief disorder at 6 to 12 months

post-loss predicts the subsequent development of major depressive disorder, PTSD, and generalized anxiety disorder in the year that follows.

Prolonged Grief and the Crisis of Meaning

Although much of the research on prolonged grief has concentrated on establishing diagnostic criteria for the disorder and developing scales for validly and reliably assessing its symptoms, investigators have also begun to study processes that could explain some of its core features. One such process is the struggle of many bereaved people to reaffirm or reconstruct a world of meaning that has been shaken by the loss, particularly when the death assaults the survivor's "assumptive world" that life is predictable and that the universe is benign. Meaning, in this sense, can have many components, including understanding the conditions that led to the loved one's death, finding philosophical or spiritual significance in the loss, deriving unsought benefit from the experience (such as revising life priorities or drawing closer to others), and developing greater maturity or strength in the course of survivorship. Across a variety of different losses—of parents, grandparents, children, siblings, and friends—research indicates that the failure to find meaning following the loss, especially in terms of "making sense" of the death itself, is associated with higher levels of complicated grief symptoms. For example, it appears that an intense and protracted search for meaning is especially likely to accompany losses that are sudden and premature, as in the death of a young person, and that a ruminative preoccupation with the loss is an indicator of long-term depression, anxiety, hostility, and grief. Moreover, a failure to find spiritual or secular meaning in the loss accounts for nearly all of the heightened symptoms of complicated grief following suicide, homicide, and fatal accidents as opposed to natural anticipated deaths (as from progressive cancer) and even natural sudden deaths (as from heart attack). It therefore could be argued that prolonged grief disorder is, among other things, a crisis in meaning induced by the loss of an important attachment figure, driving efforts to find significance not only in the loss but also in one's changed life as a survivor. Some bereavement scholars have conceptualized this in terms of attempting to heal ruptures in the client's life story introduced by the loss, through integrating it into the survivor's "self-narrative" rather than simply attempting to have the client "recover" from it.

Treatment of Prolonged Grief Disorder

Research has called into question the effectiveness of grief therapy for bereaved children and adults, perhaps in part because treatment is often offered to otherwise resilient mourners who would do well without intervention. In contrast, it is clear that those persons who display substantial symptomatology are more likely to benefit from treatment, especially when they meet criteria for complicated or prolonged grief. For example, recent research indicates that a specially designed complicated grief therapy outperformed a more general psychotherapy for carefully diagnosed bereaved people and was especially helpful for those whose losses were traumatic. A second study found that a series of thoughtfully tailored writing assignments delivered over the Internet that helped people express and explore their stories of loss substantially reduced symptoms of complicated grief relative to a no-treatment comparison group. On the other hand, it appears that antidepressant medication does little to address the core symptoms of bereavement complication, even when it usefully reduces symptoms of depression. Studies like these reinforce the conclusion that prolonged or complicated grief is a unique disorder that calls for distinctive approaches to diagnosis, assessment, and treatment.

Future Directions

Although much more is understood about prolonged grief than was the case 15 to 20 years ago, much remains to be learned. For example, little is known about the prevalence of this disorder or even its potentially unique symptomatic expressions in children as opposed to adults, or what short- and long-term consequences might follow it during childhood and adolescence. Additionally, because research on bereavement complications has centered on individuals, little is known about the family and social dynamics associated with prolonged and profound grief. Even though some

studies suggest a link between this condition and a lack of social support, it is unclear at this point whether bereaved persons who lack sufficient support are more prone to prolonged and complicated grief reactions, whether such mourners tend to exhaust or repel potentially supportive figures with their unremitting anguish, or whether both dynamics hold, so that an initially thin support network is stretched beyond its limits by the high demands of caring for someone apparently unresponsive to helpful overtures.

Despite solid scientific evidence for the legitimacy of a prolonged grief diagnosis, controversy persists about its inclusion in standard manuals of psychiatric disorders. Although some research indicates that the bereaved themselves would welcome such a diagnosis if they themselves suffered from disabling grief, some professionals are concerned that its official acceptance would contribute to "medicalizing" grieving, rather than treating it as a normal psychosocial transition, an existential challenge, or spiritual quest. Because response to bereavement is the province of diverse groups that range from hospice volunteers to professionals in such disciplines as nursing, social work, pastoral care, psychology, and psychiatry, debate concerning the inclusion of prolonged or complicated grief in medical handbooks can be expected to continue for some time to come. Even at present, however, it is clear that clinical research has expanded our understanding of the distinctive symptoms, risk factors, psychological processes, and outcomes of profound and prolonged grief, and has begun to contribute to more relevant interventions for those who suffer from this life-limiting condition.

PSYCHACHE

Psychache, a concept created by Edwin S. Shneidman and fully developed in the 1990s, refers to unbearable psychological pain most often found in suicidal individuals. The term comprehends the hurt, anguish, or ache that takes hold in the mind; the pain of excessively felt shame, guilt, fear, anxiety, loneliness, angst, dread of growing old or of dying badly. Although Shneidman admits that each suicide is a multifaceted event, that biological, cultural, sociological, interpersonal, intrapsychic, logical, philosophical, conscious, and unconscious elements are always present, he suggests that the essential nature of suicide is psychological, meaning that each suicidal drama occurs in the mind of a unique individual. Advocates of the concept focus on the mental aspects of suicide

and suggest that the study of suicidal acts should concentrate on the phenomenology of suicide.

Psychache can be clearly distinguished from depression or other psychiatric disorders for the uniqueness of suffering perceived by the subject and for the fact that he or she cannot stand it; the individual cannot see a way out and believes that ending life is a solution. Shneidman suggested investigating psychological pain referred to as introspective experience of negative emotions through the Psychological Pain Assessment Scale. This instrument rates present and worst-ever psychache and, from the standpoint of the researcher, should help clinicians and researchers explicate the concept of psychache, explore its theoretical dimensions, and begin the process of developing operational meaning between psychache and suicidal behavior.

Shneidman's great efforts to understand negative emotions in individuals and how to bridge the gap in communication of human suffering was one of the major sources of inspiration of such a concept. The pioneering challenge to introduce the psychological element in the study of suicide began in 1949 when Shneidman serendipitously found himself comparing, in blind conditions, genuine and simulated suicide notes and then trying to distinguish between the two types. In attempting to understand the mind of the suicidal individual, a major contribution was made when the first psychological autopsies were performed. These were retrospective investigations of the deceased person, within several months of death, using psychological information gathered from personal documents; police, medical, and coroner records; and interviews with family members, friends, coworkers, school associates, and health care providers to classify equivocal deaths or establish diagnoses that were likely present at the time of suicide. Taking advantage of this background and after decades of research in the suicidal mind, it was concluded that the main ingredient of suicide is the unbearable psychological pain and that suicide may be, *at least in part,* an attempt to escape from this suffering. Conceptualization of psychological pain as an ingredient of suicide is traceable in works published in the 1980s by Shneidman, such as in the classic Aphorisms of Suicide Assessment, and has some implications for psychotherapy wherein the role of psychological pain is mentioned as related to the fact that if tormented individuals could somehow stop consciousness and still live, they would opt for that solution. Shneidman believes that in suicide, *death* is not the key word. The key words are *psychological pain*, and if the pain were relieved then the individual would be willing to continue living.

In such a view, suicide is functional because it abolishes the pain for the individual. Suicide occurs when the psychache is deemed by that individual to be unbearable. It is an escape from intolerable suffering; and this construct views suicide not as a movement toward death but a remedy to escape from intolerable emotion and unendurable or unacceptable anguish.

Psychache is associated constriction or narrowing the range of options usually available to an individual. Suicidal individuals experience what may be defined as dichotomous thinking, that is, wishing either some specific (almost magical) total solution for their psychache, or cessation—in other words, suicide. A dialogue takes place in the mind where options to solve the pain are scanned. Suicide, although considered in the first steps of this process, occurs after a given length of time when efforts to find amelioration of psychache have failed.

Shneidman's view of psychache lies in the fact that the main sources of psychological pain, such as shame, guilt, rage, loneliness, and hopelessness, emerge from frustrated or thwarted psychological needs. Shneidman's conceptualization of psychological pain is deeply rooted in the psychological needs reported in Henry Murray's *Explorations in Personality*. These psychological needs include the need for achievement, affiliation, autonomy, counteraction, exhibition, nurturance, order, and understanding. It would appear that the frustration of some psychological needs cannot be tolerated, and these are needs that the person would die for. These vital needs come into play when the individual is under threat or duress. Suicide occurs in the dark moment when life has unhappy aspects, such as sorrow, shame, humiliation, fear, dread, defeat, or anxiety.

According to classical suicidology, suicide occurs when perturbation and lethality exist in the same individual. Perturbation refers to how upset, disturbed, agitated, or discomposed the individual is; lethality (also referred to as suicidality) refers to the likelihood of an individual's being dead by his or her own hand in the future. It is important to first deal with perturbation (psychache) because it

energizes lethality. In order to perform such task, clinicians should inquire about the client's psychological pain. The classical Shneidmanian suggestion is to ask key questions of the suicidal person: "What is going on?" "Where do you hurt?" and "How may I help you?" Although simple, these basic questions provide some access to inner feelings of the perturbated person.

Treatment for psychache should be performed through anodyne psychotherapy, which aims at the mollification of unbearable psychological pain. The most important key in anodyne therapy is a tailor-made focus in the alleviation of that patient's frustrated psychological needs considered by the person to be vital to continued life. Therapy of psychache involves the fact to be empathic and resonate to the patient's private psychological pain. Therapists should be aware of the uniqueness of patient's suffering and should try any possible solutions to change the patient's psychological pain from unbearable and intolerable to barely bearable and somewhat tolerable.

Psychological Autopsy

The term *psychological autopsy* refers to the reconstruction of a deceased biographical and psychological state preceding death when suicide is suspected. The procedure is used in clinical settings and within the scientific field, as well as in the development of suicide prevention and therapy programs. A psychological autopsy is conducted when the circumstances of death are uncertain. In this case investigators collect oral and written information from the environment of the deceased, such as in interviews with survivors (e.g., family, friends, and medical personnel) and documents (e.g., letters, diaries, police reports, and coroner's records). The main questions a psychological autopsy should reveal answers to are (a) How did the person die? (b) Why did the person (possibly) commit suicide? and (c) What was the exact nature of death?

In the late 1950s the term *psychological autopsy* appeared for the first time in the work of suicidologist Edwin Shneidman and his colleagues at the Los Angeles Suicide Prevention Center and the Los Angeles Medical Examiner's Office. After the investigation of a great number of unsolved death cases, Shneidman and his coresearchers developed this procedure to rebuild a person's history and to reveal the victim's motivation to commit suicide. In the first place, the psychological autopsy focuses on the last days before death, although Shneidman emphasizes that the investigation must range further than that. Survivors are asked about the personality, lifestyle, and relationships of the deceased. A brief outline of the personal history must also be provided, and questions regarding psychological stress can go back to about a year before death.

The traditional use of a psychological autopsy had been in coroners' reports in addition to the regular physical autopsy, because rather than focusing on the cause of death it focuses on its context. Furthermore, the procedure had been used in research for defining risk factors of suicide in adults. Later the research had been expanded to the investigation of suicidal children and adolescents. From the 1970s the focus shifted increasingly toward examination of risk factors, and the psychological autopsy became an important instrument for the treatment of potential suicides and failed suicide attempts. Another function had been recognized in the interviews with survivors. If the investigator is working with much accuracy and empathy, the interviews can have a therapeutic value for the bereaved. By talking about and confronting their feelings and thoughts, the survivors

are able to deal with this difficult experience. The psychological autopsy can thus be used for pre- and postvention of suicidal acts.

In the investigation of suicide, data can be divided into two sets: prospective and retrospective. The retrospective data are collected during a psychological autopsy, whereas prospective data refer to clues before death (e.g., the person talking about suicide, previous suicide attempts, feelings of depression and hopelessness). This division is important in the study of suicide because there are different clues, which therapists and doctors should be aware of. Psychological autopsies reveal that when suicide is certain as the mode of death (e.g., when a goodbye letter or a weapon in the hand of the victim is found), prospective clues can be found in almost all cases. Suicidal people are aware of the fact that they want to die, and they also think of how they will be remembered after death. Shneidman refers to the imagination of how a person wants to be remembered as the "postself." The psychological autopsy is in fact a way of measuring the postself by collecting information from the environment of the deceased. The suicide note is the most direct measure of the postself in the case of suicide. The person leaves his or her last words to the world, words that will be remembered. In other personal documents, such as diaries or notes, the postself becomes visible when the victim fantasizes how the world would be without him or her. In the analysis of retrospective data in a psychological autopsy, the postself is represented in the memory of the survivors.

To conclude, there is not a standard way of conducting a psychological autopsy. Researchers use different methods: semistructured interviews, standardized questionnaires, and written data. The multidisciplinary character and the specific study of every case separately can reveal more background information about the exact mode of death. Additionally, in the scientific field, researchers strive for standardization of the procedure so as to compare different cases more accurately. The methodological difficulties lie mainly in the diverse informants who provide different information about the deceased. Nevertheless, the psychological autopsy is a significant instrument in the investigation of death because it reaches further than the classic taxonomy of death modes (natural, accidental, suicidal, and homicidal death). Today's researchers try to combine the "classic" psychological autopsy with other methods, such as the narrative approach, by, for example, the use of life charts. The use and methods of the psychological autopsy are still under development.

Putrefaction Research

Putrefaction research is the study of decaying matter upon an organism's death. Although this area of inquiry extends to both the plant and animal worlds, the latter is the focus of this entry. When an animal dies, including human beings, there is a series of stages in which the body breaks down, or decomposes, into simpler states of matter. Within 5 minutes of death, the human body begins to decompose and will continue to do so in stages until it is reduced to mere skeletonized bone. This initial stage of decomposition can take anywhere from a few days to years, depending upon where and how the corpse is preserved and under what environmental conditions, as both factors greatly influence the rate of decay. The first stage of animal decomposition, called autolysis, or self-digestion, begins nearly immediately following the lack of oxygen in

the body. Without sufficient oxygen, cells are unable to excrete and process carbon dioxide, which results in an elevated pH level in the blood. This, in turn, poisons the body's cells and causes them to rupture, releasing cellular nutrients. Autolysis, which is an internal process whereby the body's chemicals control tissue decomposition, eventually affects every cell, typically within a few days after death has occurred. As more and more tissue and organs break down, the body begins to become fluid-like and is marked by blisters and skin slippage.

Cellular breakage continues until no oxygen remains in the body, signaling the beginning of putrefaction, a process during which microorganisms, including bacteria, fungi, and protozoa, break down the remaining soft tissues. These microorganisms ensure that the body's tissues become volatile organic compounds (VOCs), which are gases (e.g., hydrogen sulfate, carbon dioxide, methane, and ammonia) and liquids that physically alter the corpse. These VOCs attract a plethora of insects, most notably *Sarcophagidae* (flesh flies) and *Calliphoridae* (blow flies) in the early stage of decomposition, which then lay eggs on the body and feed off of the flesh.

During the putrefaction process, the body undergoes physical changes. Blood begins to pool after death and hemoglobin is broken down into sulfa hemoglobin, resulting in the corpse's now greenish hue (liver mortis). This hemolyzation process, aided by bacteria, also results in the formation of red marks along the body's veins. In time, the red markings will then turn a shade of green, a process in putrefaction called marbleization. As microorganisms continue to decompose tissues, more gases are released from the cells, especially those in the abdomen and face, and the body becomes visibly bloated and marked by a strong odor. The stomach and intestines become so laden with gases that their contents eventually submit to the pressure and are expelled from the anus. There is an increase in insect activity as compared to during the autolysis stage, although it is characteristically the same *Calliphoridae* family of insects. It is especially common in warm environments for the body to undergo saponification, the development of a pale yellow waxy or slick substance, called adipocere formation, when the body's fat deposits turn into soap due to elevated pH levels caused by bacterial activity.

As putrefaction continues into what is called the black putrefaction stage, the corpse turns from green to black as a result of the body cavity rupturing under the intense gaseous pressure. It is at this point that the bones become visible and insects and other wildlife, including scavengers, descend upon the body and expedite further decomposition. Black putrefaction ends when the body dries and the remaining tissues dehydrate and fuse to the skeleton. This drying, referred to as desiccation, is largely dependent on the climate; bodies left in warm, dry climates reach mummification more readily than those in moist areas. As the body dries out, it loses the odor that marks putrefaction because little tissue remains after scavengers have removed all organs or the organs are decomposed by way of autolysis. Once the body is without any soft tissue, it is then referred to as a skeleton. Dry decay, or the deterioration of the skeletal remains, is commonly a very long process that takes anywhere from a few years to centuries depending upon the environmental conditions and burial practices. In order for bones to decompose, the protein and minerals must separate. Bone protein and its rate of leaching away from minerals are affected by the soil type, its pH level, and the presence or absence of groundwater; as such, the bone corrosion phase is widely variable.

Research Process

Putrefaction researchers are concerned with the rate of decomposition and how myriad variables influence this process. The study of decomposition and putrefaction is called taphonomy, and these researchers are interested in the complex relationships between the environment and the decaying corpse. Often, their job is to determine time of death, an estimate that has important implications for crime scene investigations. For instance, there is a basic formula that measures putrefaction for a person lying in the ground; this formula factors in the temperature ($y = 1285 / x$, with y equaling the number of days since death and x equaling the temperature in centigrade). Typically, the warmer the temperature is, the faster the decomposition rate is, although soil conditions, cause of death, prior embalming, type of clothing, depth of burial, and presence of scavengers also drastically alter this process.

Researchers who specialize in the insect activity on and within dead bodies are called forensic entomologists. They are interested in documenting the species and number of bacteria, fungi, and insects that are present during the various stages of decomposition. When a dead body is found, criminal investigators can gain tremendous insight from the forensic entomologists' work because the presence and absence of necrophilous insects and bugs (animals that are attracted to putrid bodies) and their stage of development can help determine the time that elapsed since death occurred. But insect activity varies from place to place due to temperature and other factors, so investigators can potentially learn whether or not a person died in a given locale or if their body was moved postmortem.

The Body Farm

A body farm is a research center where scientists study the human decomposition process. These facilities provide an environment whereby death and decay can be scientifically examined by replicating various settings. Body farms are an important component to better understanding the human decay process and how particular environments may affect the deceased's body. For example, scientists may reenact a murder victim left in a body of water for days prior to discovery or a victim burned posthumously. By studying the process by which bodies decompose when left to the elements, it is possible to accurately determine the postmortem interval in real time and recover any evidence of foul play. Thus, the data collected at body farms provide crime scene investigation teams and forensic anthropologists with important information regarding decomposition and proper techniques for collecting evidence from a victim's remains and the surrounding crime scene area. Because bringing a perpetrator to justice often requires that investigators place the criminal at the scene, the body farm staff are primarily interested in accurately determining the time of death based upon the state of the body upon discovery.

Quality of Life

Much of the human experience has striven for happiness and the satisfactions of life. Well-being and satisfaction with family, job, leisure, and other domains of life characterize the quality of life (QOL). QOL developments such as measurement and research findings will be explored to show the rise of this interdisciplinary topic. Satisfaction comes from many sources, one being the idea of survival.

Survival of the species constitutes a domain of the QOL, according to R. Mukherjee, who canvassed the writings of W. I. Thomas, R. S. Lind, L. L. Thurstone, A. H. Maslow, and others in order to identify our cardinal valuations. A cardinal value of humankind is survival. Seeing one's heritage, genes, and traditions passed on to the succeeding generations before death provides gratification and fulfillment. Suicide ends the life of some, but the greatest threats to life are man-made and natural disasters. During the 20th century, 250 formally declared wars led to the demise of more than 100 million people. Genocide, pogrom, religious conflicts, and political hostility took at least 145 million lives during the 20th century. These losses affected the QOL of at least an additional 500 million. Man-made disasters have claimed the lives of thousands in the form of automobile, ship, aircraft and train accidents, explosions, mine disasters, nuclear accidents, and fires over the past 10 years. Man's adaptation to the fruits of the Industrial Revolution has come at a cost to survival.

Natural disasters also led to loss of life, crushing the QOL of thousands. In the 10 years ending 2006, earthquakes caused more than 339,000 deaths worldwide. During the same period, floods and tidal waves took more than 273,000 lives, affecting the QOL of many thousands of family members left behind. Other natural disasters have brought death to tens of thousands, including storms, hurricanes, typhoons, blizzards, and volcanic eruptions. We have not yet learned to avoid nature's fury.

Evolution of Quality-of-Life Measures

In the 1960s, the gross domestic product (GDP) was looked upon as a general but unsatisfactory index of the well-being of society. Social indicators were expected to provide more sensitive indices. They have done so. In the 1970s, scholars worldwide began to contrive better indices of well-being. Marketing scholars saw QOL measures as reflections of success in distributing goods and services to satisfy needs. Psychologists developed measures of subjective well-being. Economists and sociologists employed ecological measures of aspects of QOL to reflect the status of regions or social systems. Scholars worldwide began to survey populations and identify population categories that evidenced better or worse QOL. However, only Bhutan, in Asia, with a population slightly over 1 million, has substituted QOL measures for the economic GDP.

Conceptualization and Application of QOL Measures

Three approaches to measurement have evolved. Sensitive to health conditions, scientists studying effects of medical interventions have developed extensive protocols for QOL of people with specific health conditions or therapy needs. Psychologists, concerned with mental health and other mental conditions, have focused upon subjective well-being, measured by questionnaire items that allow the respondent to express happiness and life satisfaction. Finally, economists, sociologists, geographers, and others rely upon both survey findings and reported data combined to compare the QOL of cities, regions, and nation-states. These efforts have resulted in an understanding of segments of the population that are better or worse off and that should receive various services to improve their well-being.

Improving well-being requires knowing the areas of life that, if properly treated, would result in a better QOL. To this end, researchers have disaggregated the measure of QOL into domains. An early study conducted in the 1970s isolated five major "life concerns": job, community/neighborhood, civic/government, leisure/sociability, and fun/personal accomplishments. Others have refined this approach through factor analysis of item responses on extensive surveys. Robert Cummins reviewed 152 studies to identify their common domains, finding that 68% of domains could be compressed into seven categories: material well-being, health, productivity, intimacy, safety, place in community, and emotional well-being. These are just two examples; other definitive sets of domains have been developed during the 1990s. Abbott L. Ferriss assigned these domains to the following categories: survival of the species, social acceptance, mastery, affective autonomy, intellectual autonomy, egalitarian commitment, harmony, conservatism, hierarchy, and health. The utility of such domains lies in their relation to improving the QOL. For example, welfare would be improved through increasing the production of wealth through investment. The hierarchy and mastery domains would be improved through investment that would provide education and employment opportunities.

The Quest for Global QOL Measures

Scholars have devoted much effort to refining measures of QOL so that now reliable cross-national and international studies are possible. Health-related QOL measures are devised to reflect progress of treatment of particular health conditions. An example is the Canadian Occupational Performance Measure. It has the client identify activities of importance and rates the performance for personal care, functional mobility, community management, work, household management, and play/school. The interviewer rates the client on each of these, and the sum of the ratings provides an overall assessment. The result is used to detect progress or retrogression over time, or the effect of particular therapies. Other health-related QOL measures are for specific health conditions.

The most commonly employed measures are developed from questionnaire responses to questions reflecting the subjective well-being of the respondent. Robert Cummins developed a QOL scale that is being administered in a number of nations that will provide international comparison, while Ed Diener produced a QOL measure appropriate for detecting trends in the United States. In turn, interest in the socioeconomic progress of nations led to the development of indices of reflecting change even in less developed areas, such as Africa and Asia. European nations have also been surveyed for QOL and mental health in an extensive 10-nation study.

The United Nations Development Program has contrived a Human Development Index consisting of the measures of buying power per person, literacy and school attendance, and life expectancy at birth. These objective measures combined provide international comparisons. These are examples of the many measures that are being developed; some are designed for special populations, interests, and age groups.

In addition to subjective measures, objective measures are employed to establish the physical basis for QOL. The UN Development Index is one example. These indices include such measures as per capita income, suicide rates, length of life, environmental toxin indices, measures of housing conditions, and other such objective features that comprise the necessities of living. They usually reflect the QOL of residents of an ecological area, such as a

county or a state. Combining 12 objective measures and subjecting them to a factor analysis led to identification of four major components of the QOL: security, mastery, harmony, and autonomy. The study demonstrated the influence of the production of wealth on the QOL. A stress index by state was strongly inversely associated with the percent of the state's population involved with religion.

Worldwide, scholars have analyzed QOL surveys, both objective and subjective, and have come to some interesting conclusions. The relationship between QOL measures and per capita income follows a curve that shows an increase in QOL as income increases up to a point. Beyond that point, an increase in income prompts little increase in QOL. The point in the curve appears to represent adequate income for life's necessities, beyond which income prompts only small increases in QOL.

This relationship is further explored by U.S. data from the General Social Survey that carries happiness and family income items. It shows families with high incomes to be 57.3% happy and 5.3% with high income "not so happy." At the other extreme, low-income families are 30.9% happy, while only 6.5% are "not so happy." These figures add to 100% of the GSS sample of families. Obviously money has some impact on happiness, but it is not the only influence. Perhaps the Roman, Cicero, found the key to happiness: "…a happy life consists of tranquility of mind." Tranquility of mind and other positive happy modes are lodged, recent research shows, in the left prefrontal cortex of the brain, perhaps indicating that happiness can be nurtured through mental training. But populations of countries vary in happiness. Switzerland, Sweden, the United States, and Argentina rank high, whereas Zimbabwe, Russia, and India rank low, according to the World Database of Happiness.

Studies show that participation in religious activities is associated with happiness. It may be that happy people gravitate to religious services, but it is more likely that religious values and the association with other like-minded members contribute to happiness. Doctrinal differences of religious bodies evidently have an effect; evangelical and fundamentalist religious adherents report themselves happier than other mainline and liberal bodies. People with no religious affiliation rank lowest in happiness.

While the notions of welfare and happiness have enjoyed academic interest, the general concept of QOL is relativity new. Its future in policy and program development, research, and general usage promises to expand. This will depend on several developments. With governmental interest in improving the general welfare, QOL measures could be the criterion. QOL surveys identify population segments in need of attention. With attention through publicly supported programs, QOL assessments of progress will be needed. The current suggestion of a periodic national survey of QOL of the country, following the lead of some European countries, will become a reality. QOL measures should then augment or supplant GDP as a measure of the general welfare of the population.

The Social Quality Concept

Social theory should be enhanced though employing QOL as a criterion for social studies, as personality dimensions and mental health measures have sometimes been used in the past. Research will improve our understanding of well-being and will be an important ingredient of QOL theory.

There is a rising interest in the ingredients of the good life. European scientists have advanced the concept of social quality, seeking to conceptualize it in terms of a fourfold matrix including socioeconomic security, social inclusion, social cohesion, and social empowerment. Thus, the concept of QOL is expanded from an individual condition of well-being to a social environment of social forces conducive of the good life. A theory of social quality with special reference to health has been developed.

Race and Death

The concept of race is used to differentiate among groups based on criteria such as physical characteristics (e.g., skin color and hair texture) and sociocultural heritage. Ethnicity is a concept that focuses primarily on sociocultural heritage. In the study of health status, including death rates, race tends to be emphasized in order to compare differences between racial/ethnic minorities and the white majority group in society. Although there have been significant declines in overall death rates in the United States, health disparities persist across racial/ethnic groups. This review first identifies the major racial/ethnic groups in the United States. Second, the interaction between race, poverty, and death rate disparities is discussed. Finally, there is a call for further research to better understand factors that contribute to the large and persistent gap in mortality between racial/ethnic minorities and the white majority population.

U.S. Major Racial and Ethnic Groups

According to the 2000 U.S. Census, the racial/ethnic makeup of the American population was 12% African Americans, 3.6% Asians, 0.1% Native Hawaiians and Other Pacific Islanders, 0.9% American Indians and Alaska Natives, 13.3% Hispanics, and 70% non-Hispanic whites. Most blacks have ancestors who were African natives brought to the Americas as slaves. Other blacks belong to newer immigrant African groups from the Caribbean, Haiti, or other areas in the West Indies and South America. Asian immigrants came from more than 30 countries of origin in the Far East, Southeast Asia, or the Indian subcontinent. Native Hawaiians and Other Pacific Islander populations are from Hawaii, Guam, Samoa, or other Pacific Islands, while Hispanic or Latino Americans are people of mixed racial heritage who come from Cuba, Puerto Rico, Mexico, or other countries of Central and South America. American Indians and Alaska Natives are a relatively small but growing segment of the U.S. population and are native to North, South, and Central America. Non-Hispanic whites are people who immigrated to the United States from Europe, the Middle East, or North Africa. Currently, white Americans form the numerical majority in the United States, and collectively are better educated and economically situated than other racial/ethnic minorities, with the exception of Asian Americans.

Health Disparities by Race

It was long thought that racial health disparities were due to genetic differences in human populations. However, recent developments in the fields of genomics and medicine have shown that racial groups are more alike than different. Therefore, a focus on biology to explain health disparities underestimates the role that social, political, and environmental structures contribute to health outcomes. The life expectancy of most racial/ethnic minorities is shortened by social and economic inequalities and injustices that make for harsh

living conditions and exposure to racism, prejudice, discrimination, violence, and poverty.

The Interaction of Race, Poverty, and Mortality

Research has indicated that health care and health status in the United States are stratified by income, race/ethnicity, education, and occupational status. Educational attainment and high socioeconomic status are positively correlated with health and mortality advantage, whereas low socioeconomic status and poverty are linked to health disadvantage. Poverty is strongly associated with mortality among racial/ethnic minorities, who are often living in substandard housing; experiencing high rates of unemployment or underemployment, often with inadequate or no health insurance; and are often victims of violent acts, drug use, and other threats to personal health and well-being. Area-of-residence studies consistently link high mortality with high-crime areas, high crime being more likely to occur in low-income communities.

Studies of poverty trends by race show that over the life course 9 of every 10 blacks will have been exposed to poverty in the first 6 years of life, while slightly more than one half of the white population will spend 1 year of their adulthood at or below the level of poverty. Studies of older racial/ethnic groups show that 72% of older white people have earned a high school diploma, compared to 44% of blacks, 21% of Hispanics, and 65% of Asians.

African Americans and American Indians/Alaska Natives have experienced more extreme poverty than have other racial/ethnic groups. Individuals who experience no poverty in their lifetime live, on average, 10.6 years longer than those who experience bouts of poverty. Poverty increases mortality risks for entire families when there are insufficient resources to stabilize health-promoting routines, such as meal preparation, rest and sleep, exercise, and necessary support systems.

Disparities in Racial/Ethnic Mortality Rates

Non-Hispanic whites are typically used as a baseline for comparing racial/ethnic health and death disparities. Disparities exist in the area of life expectancy, with African Americans dying at higher rates and at a consistently higher level across the life span in comparison to whites and other racial/ethnic groups. Life expectancy for whites is about 7 years longer than for black Americans. African Americans are more than twice as likely as whites to die in infancy and in the age group 20 to 24. Black men and women die of cardiovascular disease and stroke more than any other diseases. The prevalence of hypertension in African Americans in the United States is among the highest in the world. Compared with whites, African Americans develop high blood pressure earlier in life, have higher blood pressure readings, and experience more complications. Risk factors for heart disease include diabetes, high blood cholesterol levels, high blood pressure, obesity, physical inactivity, and tobacco use. African Americans tend to have two or more of these risk factors as compared to whites. African American women have a higher prevalence of cardiovascular risk factors than white women of comparable socioeconomic status. African American women without a high school education have a higher prevalence of obesity compared to white women of similar educational status.

The major causes of death for Hispanics are heart disease, cancer, and accidents. With the exception of Hispanic young adults ages 20 to 24, no significant differences exist in mortality when compared to non-Hispanic whites. This finding is the opposite of what would be expected since research links mortality to low socioeconomic status and limited access to health care. Several hypotheses are proffered to explain Hispanics' mortality advantage or tendency to have consistently lower death rates than non-Hispanic whites; these hypotheses include lower age-specific death rates at older ages; underreporting of Hispanic origin on the death certificates; healthy migrant effect, which suggests that persons with good health are more likely to immigrate; and "salmon bias," the tendency of many Hispanics to return to their country of origin when ill or to die. The literature also suggests that the Hispanic advantage is associated with the large number of new immigrants found within this population and the tendency of immigrant groups to settle in communities that perpetuate cultural traditions with more naturally occurring networks that provide financial, social, and emotional support. The capacity to retain one's language and strong social networks

are protective factors that promote resilience and buffer the negative effects of external social forces linked to mortality.

Similarly, Asian Americans show a mortality advantage when compared to whites and other racial/ethnic groups, regardless of age. The major causes of death for Asian Americans are cancer, heart disease, and stroke. Asian American women have the highest life expectancy, and as a group, Asian Americans have the highest household income and percentage of college graduates of all racial groups, which may in part account for the mortality advantage. However, researchers express concerns about the reliability of current findings associated with the mortality advantage because of the large number of foreign-born Asians, the healthy migrant effect, the salmon bias, and the prevalence of underreporting in the federal census data. And there are disparities in health and death rates within the diverse Asian American population. Particularly puzzling are the extremes that show that Indian women who have resided in the United States for a long period of time do not share the advantage, whereas the Vietnamese, who have the lowest socioeconomic status, have a greater health advantage than other subgroups of Asians.

Underreporting of personal and health information by American Indians and Alaska Natives and limited access to their medical records have caused problems in linking health and mortality within and among these population groups. Systematic health information has been collected only for American Indians and Alaska Natives residing on federal reservations; these data show they experience high mortality compared to whites. For Native Americans age 65 years and older, mortality

is 40% higher; among infants, 60% higher; and among young adults, ages 20 to 24 years, almost twice as high as for whites. This population has disproportionately high death rates for unintentional injuries and suicide. In addition, this group has higher rates of cigarette smoking, alcoholism, and diabetes. High rates of mortality and morbidity (chronic illness) within the Native American and Alaska Native populations are correlated with their overall low educational attainment, poverty, geographic isolation, poor access to health care, and cultural differences.

Figure 1 compares age-adjusted death rates for all causes of death, by race and Hispanic origin, for the United States for selected years from 1950 to 2005. Age-adjusted death rates are based on a standardized population of 100,000 people. The figure confirms that age-adjusted death rates for all causes have decreased for all racial/ethnic groups since 1950, with a more gradual decline since 1980. Although current research fails to fully explain all the factors that contribute to high death rates in some groups versus others, these data highlight the differential impact that multiple factors seem to have on the relationship between race and death.

In sum, many factors predispose people to mortality, including genetic variations, environmental exposures, health behaviors, socioeconomic status, psychosocial stresses, limited resources, stereotyping, discrimination, and lack of access to health care. For nearly every disease tabulated by the Centers for Disease Control and Prevention, the non-Hispanic whites live healthier and longer than do most minority populations.

Reincarnation

Reincarnation is the belief that individuals are somehow able to survive bodily death by taking birth again in another form. A belief in reincarnation is universal and persistent, found in various versions on nearly every continent from ancient times to the present day. Evidence supports nearly equal antiquity of belief in reincarnation in Africa, Asia, Europe, and the Americas. Because a complete list of the numerous religions and philosophies, ancient and modern, which affirm some form of reincarnation would be too large a subject to cover in this entry, the following necessarily treats the topic selectively, not comprehensively. The views selected represent the wide-ranging versions and variations of belief in reincarnation from ancient times to the present throughout the world, in particular, in India, Ancient Greece, Africa, the British Isles, and North America.

India

At least as early as the 8th century B.C.E., the idea of reincarnation appeared in the Upanishads, part of the authoritative revelation of reality for most Hindu religious and philosophical traditions. Reincarnation is described there metaphorically in this way: As a caterpillar inches its way from the leaf of one plant onto the leaf of another plant, so

the soul leaves behind one body and crosses over into a new one.

Birth and death are recurring events that punctuate the beginningless and endless cyclical syndrome known to indigenous Indian religions (Hinduism, Buddhism, Jainism, and Sikhism) by the Sanskrit term *samsara*, meaning flows together or wanders. Samsara metaphorically pictures the incessant flow of the simultaneity of birth and death, with people at every moment entering and exiting the world, wandering from one birth to another in search of liberation and release from the otherwise beginningless and endless repetition of reincarnation. Hence philosophically speaking, reincarnation is a predicament, not a solution. Philosophically speaking, birth is a mistake but it can be corrected through liberation from the cycle of birth and death.

The desire for liberation has never been normative or popular in India but ideal and exceptional. More popular aims of life are of equal religious legitimacy, including the pursuit of sensual, aesthetic, and sexual pleasure, and the ambition for social success in the form of material wealth, prestige, and power. Most Hindus seek meaningful lives pursuing pleasure and success and take consolation in the doctrine of reincarnation. For them reincarnation promises that death is not the end and provides unlimited opportunities to experience the innumerable pleasures and to pursue promising prospects of social success. However, to those exceptional individuals in each generation of Indian society who seek liberation above all else, the very same doctrine of reincarnation presents a problem to overcome, not a therapeutic remedy for human anxiety about facing finitude. The person who transcends reincarnation discovers the deep innermost self known as Atman, the birthless, deathless, changeless ultimate Self underlying all of the changing personalities that take repeated births until the true Self (Atman) is realized.

The doctrine of reincarnation in India also addresses and answers the psychological need to provide an explanatory account of the world that satisfies the human desire for justice in the universe. By doing good, a person becomes good; by doing bad, a person becomes bad. Reincarnation functions as a cultural vehicle of social cohesion in India. Far from instilling fatalistic attitudes, the doctrine of reincarnation, which is governed by the principle of karma, serves as a powerful motivation for good moral behavior and exerts a restraining influence on antisocial impulses and inclinations. Reincarnation is driven by the principle of karma, which asserts that all human volitional actions engender results that the performer of the actions must live to face and experience somewhere, sometime, somehow—in pleasure or pain—sooner or later in this life or a future reincarnation. For example, the ancient code of Manu warns that a student who depends too much on the teacher for material support will be reborn as a worm, and the one who speaks disparagingly about the teacher, even though the teacher may warrant it, will be reborn as a bug. People obsessed with food and driven by gluttony are reborn as pigs.

Early forms of Buddhism in India delineated six realms of reality through which beings are constantly recycled unless and until they realize nirvana (the extinguishing of desire for separate and permanent existence). The six realms were all present in pre-Buddhist Indian cosmology, but Buddhists approached it from a different perspective, situating them in the center of the wheel of becoming, also known as the twelvefold chain of causation or the doctrine of interdependent origination. This doctrine explains how all things exist, not as separate and enduring things in themselves, but merely as processes in utter interdependence. The six realms into which reincarnation can occur include gods in heaven, animals and humans on earth, and hungry ghosts and demons in hell. For both Hinduism and Buddhism, neither heaven nor hell is eternal or irrevocable—rather, both are temporary abodes in which pleasure or pain is experienced for a length of time commensurate with one's actions in prior human existences.

Buddhism historically denied the existence of an unchanging eternal self yet maintained belief in reincarnation. If there is no self, what exactly gets reincarnated? The fundamental will to be, to exist, to grow, to become more and more is the most powerful force in the universe; it is this energetic will to be that incarnates itself repeatedly until the will to be is extinguished in the realization that to be or not to be is neither the question nor an option. Existence entails change and whatever does not change does not exist. Unlike the liberation (*moksha*) of Hinduism—which escapes the realm of change to encounter the changeless, birthless,

deathless reality of Atman—Buddhist nirvana entails the practical awareness that there are no persons, places, or things that possess the characteristics of independence and permanence. For enlightened people there is no difference between samsara and nirvana; samsara is existence lived in ignorance about how things really are, entangled in the imagination that things are separate and enduring; in contrast, nirvana is existence lived in the experiential awareness of the emptiness that leads to detachment.

While escaping reincarnation was an agenda for early Buddhists, the later and larger development in Buddhist thought, known as Mahayana, produced a new ideal that enlightened ones (bodhisattvas) take a vow to be reincarnated continuously unless and until everyone becomes enlightened. Hence the meaning of the Mahayana slogan that there is no nirvana apart from samsara. There is nowhere else to go outside of the six-samsaric realms of suffering to experience nirvana.

Ancient Greece

Ancient Greeks held versions of reincarnation at least as early as the 8th century B.C.E. Metempsychosis, or transmigration of the soul as it was also known to Greeks, was made popular by Pythagoras, the famous 6th-century B.C.E. mathematician. Pythagoras's version of reincarnation was situated in a different cosmological context than that of India. Rather than seeking escape from the rounds of reincarnation, Pythagoras held that the goal of life was to exist within the cosmos in a state of intellectual alertness and emotional peace and to live in harmonious microcosmic relation to the macrocosmic universe. By ascetic and ethical practices such as vegetarianism, a person could purify the soul for an improved rebirth on earth as a person and avoid regressing to rebirth as an animal. Earlier than Pythagoras, the 8th-century B.C.E. religious society known as the Orphics espoused a version of reincarnation strikingly similar to some found in India. Orphics believed in a divine origin of the soul, which became imprisoned in the body from which it seeks ultimate release through a series of incarnations culminating in liberation from bodily form and return to its original divine status. Empedocles, the 5th-century B.C.E. Greek philosopher, claimed to have lived the lives of a boy, girl, bush, and a fish. Plato and Socrates also entertained and employed theories of reincarnation as rhetorical devices in their advocacy of a life lived as a philosopher in pursuit of virtue and wisdom.

Africa

Some African traditions hold distinctive versions of reincarnation, which may be described as partial and limited reincarnation. Reincarnation is limited because people are only reincarnated as humans and only within one's own family. The reincarnation is partial because only some distinguishing physical features or personality traits reincarnate into a descendent, but the essential individuality of the person is preserved as distinct, autonomous, and independent of the descendent into whom only some traits have passed. The Yoruba epitomize and dramatize one paradigmatic African version of reincarnation in the names given to their newborn children: Iyabo—mother returns; Yetunde—mother comes back a second time; Babatunde—father has come again; Omutunde—child comes back again. The transmission of vital lineage character traits ensures the continuity and perpetuation of the family and clan in whose interest reincarnation serves to preserve collective, not individual, identities.

British Isles

European versions of reincarnation are even more partial and limited than African ones. Celts of the British Isles restricted reincarnation to divinities and heroes; there is no evidence for mortal reincarnation. Divinities can transmigrate into forms ranging from insects or worms and birds to herds of varying animals, even to children. According to one myth, Etain, a goddess, was an insect who fell into a cup of wine from which she was swallowed by Etar. Eventually Etain was reborn as a child who had no recollection of existing as a goddess in her past life. Divine amnesia is also a common Hindu motif for explaining the descent of divinity into humanity. The divine becomes human and, having forgotten its transformation, the human seeks to rediscover its true divine identity. The similarity of this motif in the Celtic and Hindu traditions brings us full circle from East to West

and back to a meeting in the middle, where the Indo-European origins of Celtic and Hindu ideas of reincarnation are blurred in the never completely settled dust of antiquity.

Modern North America

One important foundation for the popularization of reincarnation in modern North American New Age religions was established in New York City in 1875 by Helena Blavatsky, a Russian immigrant to America who founded *theosophy*, an eclectic philosophy integrating elements of Eastern and Western religions. The theosophical doctrine of reincarnation espouses a progressive evolutionary development of the soul through a series of reincarnations. The soul is always learning in order to move forward toward ultimate transcendence of bodily existence and to return to an original pristine and primordial bliss.

New Age religions' popularization of belief in reincarnation gave birth to a new field of parapsychology called past life therapy. Past life therapy employs clinical hypnotherapy to facilitate memories of an unconscious past life, emotionally traumatic experiences, and psychological or interpersonal conflicts. Under the guidance of a trained therapist, some Americans pursue New Age visions of wholeness by recalling, investigating, reconciling, and resolving repressed memories from previous lives.

From ancient India to modern Indiana and everywhere and at all times in between, various versions of reincarnation have persisted in addressing and answering basic human social and psychological concerns. Human beings have universally and persistently experienced anxiety about facing finitude and generally do not favor ambivalence or ambiguity; instead, they prefer clarity and certainty, especially in matters of such momentous existential concern as death in human experience. Beliefs in reincarnation are as diverse as the cultural religious imaginations that conceived them, ranging from interpreting rebirth as a mistake that can be corrected, on the one hand, to celebrating rebirth as a reward for a noble past life, on the other. Depending on the particular cultural religious context, reincarnation may be a good thing or a bad thing. Regardless of whether reincarnation is viewed positively or negatively, belief in reincarnation serves a psychologically and existentially therapeutic purpose, namely that it provides meaning for the pursuit of individual and collective corporate human wholeness, fulfillment, completion, and perfection.

Resurrection

Resurrection means rising from the dead. The word comes from Middle English, Anglo-French, and Latin (from *resurrectio* "the act of rising from the dead," from *resurgere* "to rise from the dead," from Latin *re-* "again" + *surgere* "to rise"). The word *resurgence* has similar roots. The best-known example of resurrection would be the resurrection of Jesus Christ. This is seen by Christians as a model for the resurrection of all dead humans that will take place before the final judgment. *The Catholic Encyclopedia* defines *resurrection* as "rising again from the dead, the resumption of life." This last part makes a distinction between resurrection and reincarnation—which would see the lifeforce or soul move to a new life rather than resuming a previous one.

Egyptian and Zoroastrian Beliefs

Perhaps the first reported resurrection was that of the Egyptian god Assur (later called Osiris by the Greeks). The story is told that Assur was on a trip abroad and left his kingdom in the care of his wife, Isis. As he was returning to the Nile Delta from one of these trips, Assur was murdered by the evil

god Set. His body was hacked into pieces and the parts were scattered. Isis found and gathered the body parts of Assur, put them back together, and resurrected Assur from the dead. She then joined with Assur and their union produced a son, Heru. Assur/Osiris became king of the afterlife. Isis became the earth-mother (and the first "Eve"). Heru was the first pharaoh to whom all other pharaohs traced their ancestry and from whom they received their divinity and immortality.

The earliest discussion of general resurrection can be found in the teachings of Zoroaster between the late 7th century and early 6th century B.C.E. Zoroaster taught that each individual would be judged at the end of life, but at the end of the present world order there would be a general resurrection of all dead humans and, at that time, a fire would cover this world and the next and separate the evil and the good. The evil would be consumed by the flames. The good, or righteous, would not be harmed by the fire because they had no evil in them and no need to be purified by the flames. At that time Angra Mainyu and his devils would be driven away forever. The idea of resurrection remained a part of Zoroastrian belief and influenced the followers of other religions, including Judaism.

Resurrection and Jewish Belief

The Sadducees (the clan that provided the priests for the Jews) sought to purify Judaism and rejected beliefs they felt were counter to the teachings of the Torah, and the five books of Moses in particular. One of these rejected ideas was the belief in the resurrection of the body to "full consciousness" in the afterlife. For the Sadducees to want to reject it, the belief in resurrection must have been present in Jewish thought of the time. Even today, among the 13 cardinal principles of the Jewish faith is the final one, which says that a Jew reciting the cardinal principles believes with perfect faith that there will be a resurrection of the dead. In the Orthodox Union translation, Principle 13 says, "I believe with perfect faith that the dead will be brought back to life when G-d wills it to happen." This statement seems consistent with the beliefs concerning resurrection in Zoroastrianism. When Reform Judaism was growing in the mid-19th century, references to belief in the Messiah and the resurrection of the dead were dropped from their Sabbath service, leaving belief in resurrection as an Orthodox tenet.

The Torah/Old Testament contains several passages that speak of resurrection. In 2 Maccabees one of the martyrs says that if his body is taken from him, it will be restored again (12:11; cf. 9:14). The Book of Daniel (12:2; cf. 12) mentions the same belief. Ezekiel (37) shows the belief in a literal resurrection, and Isaiah says that "dead men shall live, my slain shall rise again . . . the earth . . . shall cover her slain no more" (26:19–21). Finally, Job was strengthened by the thought of the resurrection of his body: "As for me, I know that my Redeemer lives, and at the last He will take His stand on the earth. Even after my skin is destroyed, yet from my flesh I shall see God whom I myself shall behold and whom my eyes will see and not another. This hope is laid up in my bosom" (Job 19:25–27).

Resurrection Belief Among Christians

Early Christians held belief in resurrection from the beginning of the faith. Christian writings about resurrection date back to Saint Paul, circa 57 C.E. However, the resurrection that Paul spoke of may have been a "spiritual" resurrection. Paul said that a physical body could not enter heaven since it was bound to decay and decay could not share in a state that was eternal. Paul described some who had witnessed the resurrected Christ as "having fallen asleep." They spoke of death as "going to sleep" until the final day of judgment. Christian Scientists use the word *resurrection* to describe a "spiritualization" of thought, since matter is seen as illusion. Belief in the material leads to a spiritual understanding. Contemporary Christian Science teaches that Christ did rise from the dead in both spiritual and physical form. The idea of spiritual resurrection causes some difficulty. The soul is said by Christians to be immortal. As such, it cannot "return" to life because it is immortal and does not die. It is only the physical body that dies and can be resurrected with a "return" to life.

The biblical account of spiritual resurrection offered by Paul does not agree with the accounts of Luke and John. They saw the resurrection of Jesus as a physical event, with the body and soul reunited. This belief is contained in the Apostles' Creed, a statement of basic Catholic belief, which says, "I

believe in . . . the resurrection of the body and life everlasting." Martha, Lazarus's sister, showed her Jewish belief in resurrection when she said to Jesus, "I know that he [Lazarus] shall rise again, in the resurrection at the last day" (John 11:24).

There is a distinction between the resurrection of Jesus and the general resurrection promised to Christians. After the apparent differences among biblical accounts are set aside, there is agreement on a number of points regarding the resurrection of Jesus. These points include the belief that after his resurrection, Jesus appeared to one or more people.

- In his gospel, Matthew describes Jesus's appearance to holy women and again on Mount Galilee.
- Mark says Jesus was seen by Mary Magdalene, by the men on the road to Emmaus, and by the 11 remaining apostles before his ascension.
- Luke describes Jesus's appearance on the road to Emmaus, to the disciples in Jerusalem, and to Peter.
- John speaks of Jesus's appearance to Mary Magdalene and 10 of the Apostles (all but Thomas) on Easter Sunday.
- Paul tells of the appearance of the risen Jesus to Cephas, to the 11 Apostles, to 500 believers, and to Paul himself.

The Story of Lazarus

Another example of Christian belief in resurrection is the story of Lazarus. Lazarus died and, at Jesus's command, was said to have been raised from his tomb with body and soul united. This resurrection took place 3 days after Lazarus's death. The time interval is important because Jews did not believe the person was truly dead for the first 3 days and because it was a symbolic prediction of the time spent by Jesus in the tomb after his death on the cross. This story was used as an example of the reward—triumph over death—that was offered to all Christians who believed in the teachings of Jesus.

Proving Versus Defining Resurrection

Theologians who believe in resurrection do not typically attempt to prove it and limit themselves to defining it. The existence of general resurrection seems unable to be proven by reason alone. It is accepted in a number of religious traditions as an article of faith (belief without concrete proof). However, there are some ideas that believers point to as supporting belief in resurrection; these are the following:

- The lifeforce, or soul, and body have existed together from the start of the individual's life, and a permanent separation would seem unnatural. This point can be seen in Matthew 22:23–32.
- The body joins the soul in all its deeds, both good and evil. Therefore it seems fair and just that the body share in the soul's reward or punishment (see 1 Cor. 15:12 and 2 Thess. 1:4).
- The separation of the soul and body seems to leave the soul "incomplete." If that is true, the completion of the person's happiness in eternal reward seems to demand the resurrection of the body. Jesuit priest and philosopher Pierre Teilhard de Chardin took this argument one step further and said that the person's world would also rise again, or fall, with the individual and that animals and nature would also be resurrected to complete the individual.

The Bible has many images of life being restored not only to dead people but to things in nature as well. The latter can be seen in the blossoms that sprang from Aaron's staff, the grain of seed dying and springing up again, the symbolism of the egg, the seasonal cycle of the year, and the succession of day and night. These images appear in early Christian art. However, Christian theologians are more inclined to believe that without divine intervention, in nature there would have been no resurrection of the body.

The Resurrected Body

Like creation, resurrection is seen as a work of God. However, the body is said to be transformed by resurrection, since it would now be immortal. The just will enjoy endless happiness in their restored bodies, while the wicked "shall seek death, and shall not find it, shall desire to die, and death shall fly from them" (Rev. 9:6). Every resurrected body is said to now share the characteristics of identity (individuality is maintained), entirety (the body is complete in a glorified state), and immortality. Catholics, and some other Christian

traditions, share a belief in other qualities. These are the following:

- Impassibility: The resurrected body is beyond the touch of any pain or suffering.
- Brightness/glory: The saints are said to "shine like the sun," and the body, though a glorified *physical* object, becomes more like the spiritual soul it has rejoined.
- Agility: The chosen are referred to as "the quick" and can move as fast as the soul desires.

Ideas and projects, like people, can also be "resurrected"—brought back to life in a metaphorical sense. In this regard the word takes on a secular meaning to accompany its religious meaning.

There are numerous beliefs concerning resurrection, and there is much misunderstanding as well. As Madigan and Levenson point out, Christian belief in resurrection is deeply rooted in the Jewish faith and culture from which Jesus emerged. It is not Christianity moving out to a new life from an earth-bound Judaism. It is a belief that would see all people resurrected together. For that reason it is not really an individual concept, because in both Judaism and Christianity it describes a collective resurrection of all people at the end of time.

In contrast to reincarnation, something to be "escaped" through a final release from the cycle of birth, life, decay, and death, resurrection is seen as a positive image—at least for the just. For those who believe in the positive future offered by resurrection, it can provide optimism, even in the most difficult of times. A belief in resurrection can allow even those people in despair to believe that every life can continue and that it can "end" on a positive note—a final reward for a life well lived.

Resuscitation

Resuscitation signifies the act of returning an individual to life from an unconscious or death-like condition. The fundamental distinction between life and death is universally acknowledged, but the notion of reversibility of death varies greatly across cultures and time. The spirituality of many cultures frequently incorporates ideas of the immortality of the soul and occasionally the body as well. Western civilization's emphasis on the opposing duality of spirit versus body has determined that resuscitation be relegated to the realm of physical phenomena. Resuscitation is best understood in its historical, medical, cultural, legal, and ethical contexts.

The dependence of life on the flow of air and blood has been recognized in many cultures for thousands of years. There is evidence that resuscitative techniques, including attempts to restore circulation and breathing, were utilized at least back to biblical times in the Near East. Resuscitation in modern societies is viewed principally within a medical framework. Progressive scientific understanding and manipulation of normal and abnormal human physiology have achieved the reversibility and prevention of many diseases. The development of cardiopulmonary resuscitation (CPR) in the 1950s was based on decades of research using animal models. Initially CPR was intended for patients in hospital settings, but its use has been expanded to out-of-hospital settings as well. Medical resuscitation began with basic mechanical restorative interventions, but it has grown to encompass sophisticated electrical and pharmacological modalities.

Resuscitation Procedures

Currently there are widely agreed upon resuscitation procedures for witnessed and unwitnessed

cardiopulmonary arrests. Initial efforts include (a) chest compressions to approximate the pumping of the heart and (b) mouth-to-mouth breathing to provide oxygen and allow exhalation of carbon dioxide. These procedures restore, at best, 60% of normal physiological function. Trials of mechanical chest compression devices have not demonstrated significant improvement over chest compressions performed manually. Mechanical ventilation with oxygen-enriched air after placement of a tube in the trachea, however, clearly has advantages over mouth-to-mouth breathing. The interdependence of respiratory failure and cardiac standstill requires that resuscitative efforts be directed toward *concurrent* restoration of respiration and circulation.

Scientific investigation into the immediate causes of cardiopulmonary collapse has revealed several potential antecedents: inability to move or exchange oxygen and carbon dioxide, cessation of electrical activity within the heart, ventricular fibrillation (disorganized electrical activity leading to ineffective heart pumping), and mechanical interference with the pumping action of the heart. For out-of-hospital cardiorespiratory collapse, the most common cause is disordered ventricular electrical activity. Reversal of the cause is currently the goal of advanced life support. Ventricular fibrillation, for example, may be reversed by electric shock applied externally to the chest. Because of the rapid accumulation of noxious metabolic products during periods of absent or inadequate cardiopulmonary function, pharmacological interventions are also required. Asystole (absence of cardiac electrical activity) and electromechanical dissociation (pulseless cardiac electrical activity) have proven more resistant to current therapeutic modalities.

Outcomes of Cardiopulmonary Resuscitation

The original intention of CPR was restoration of adequate respiration and circulation as a *temporizing* measure, allowing treatment of the underlying condition(s) causing the arrest. Ultimately, cessation of respiration and circulation is the final event in all dying processes, but underlying conditions have significant influence on the success of resuscitative efforts. Coronary artery disease and associated cardiac electrical disturbance are the most common underlying diagnoses resulting in cardiopulmonary arrest. Modification of certain risk factors such as elevated cholesterol and hypertension has been demonstrated to delay or prevent coronary artery disease and concomitant decrease in arrests. Installation of permanent antifibrillatory devices has lowered the risk of arrest in many patients.

In the industrialized world, awareness and availability of CPR have continued to increase, but clinical outcomes are consistently suboptimal. Between 5% and 20% of resuscitated patients (both in-hospital and out-of-hospital) can be expected to survive. Because brain function is highly dependent on adequate oxygen delivery, it has become apparent that CPR could be successful in restoration of cardiopulmonary function, but temporary or permanent brain damage might result. Of those who survive resuscitation, at least 50% have temporary or permanent neurological dysfunction.

Outcomes depend on many factors: expertise and experience of the initial responder, existence of coordinated systems conveying a patient to the hospital for emergent care, presence of coronary artery disease, type of cardiac electrical malfunction, and degree of reversibility of underlying diagnosis. A significant portion of health research is devoted to improving resuscitative techniques as well as coordination of systems promoting efficient delivery of these technologies both in and out of hospital.

Do Not Resuscitate

Western civilization has strongly emphasized the value and importance of life; consequently, death is frequently perceived as intrinsically evil. Consistent with this orientation, legal and medical institutions of most countries favor the preservation of life whenever choices can be made. Nevertheless, in the past 40 years legalization of abortion in the United States and physician-assisted suicide in Oregon have somewhat countered these policies. The high value placed on personal autonomy in Western civilization has prioritized legal recognition of the right to choose or refuse medical interventions, including CPR. Although the default in medical environments is maximal effort toward preservation and prolongation of life, most technologically advanced societies allow an individual (or surrogate) refusal of any medical intervention even though death is likely to result. Modern societies have begun to confront conflicting medical,

ethical, and legal imperatives amid rapidly advancing resuscitation technology and slowly improving outcomes.

Right-to-Die Movement

Although interest in end-of-life issues has waxed and waned during the 20th century, a recent resurgence of public attention to this topic has occurred in the United States. Specifically, a host of social and cultural forces have spurred an effort to legalize terminally ill patients' rights to control the manner and circumstances surrounding their death. Factors such as the rapid growth of medical technology and an increased emphasis on personal autonomy have given rise to the right-to-die movement. This large-scale social initiative has advocated for the right of terminally ill patients to refuse medical treatment, to forego life-sustaining technology, and to request options such as physician-assisted suicide and euthanasia.

Although some scholarly discussion of individuals' right to die appeared as early as the 19th century, the right-to-die movement in the United States did not emerge as a significant social force until the 1970s. The event that pushed right-to-die issues to the forefront of public attention was a New Jersey Supreme Court ruling concerning patients' rights to withhold life-support intervention. The case, known as *In re Quinlan,* was instigated by Karen Ann Quinlan's parents, who fought for the legal right to discontinue their daughter's life support. After considering the Quinlans' arguments, the New Jersey Supreme Court ruled that patients and their surrogates have a right to refuse unwanted medical treatment, even if this action hastens the patient's death. This ruling established a legal precedent for patients' rights to refuse life-support interventions. It also had a dramatic impact by instigating statewide legal action supporting the use of advanced directives. Finally, *In re Quinlan* drew tremendous social attention, bringing end-of-life issues to the forefront of public discussion and giving momentum to the right-to-die movement.

Taking advantage of the public attention raised by Quinlan's case, in 1980 the British journalist Derek Humphry founded the Hemlock Society, a right-to-die organization that aimed to further expand patients' options near the end of life. Specifically, Humphry argued that terminally ill patients should not only be able to refuse unwanted medical treatment but also to request active aid-in-dying by means of assisted suicide and euthanasia. The foundation of the Hemlock Society marked a shift in attention from refusal of treatment to the legalization of physician-assisted suicide. Over the next 2 decades, the Hemlock Society became a major force in the right-to-die movement and spurred efforts to legalize assisted suicide at the state and national levels. It was soon joined by other right-to-die groups, such as Compassion in Dying, which was founded in 1993 in Washington State.

During the 1990s, the Hemlock Society and Compassion in Dying made considerable efforts to legalize aid-in-dying and to decriminalize assisted suicide. In 1990, the Hemlock Society sponsored Washington State's Initiative 119, the first state referendum asking voters to decide on the issues of legalizing physician-assisted suicide. The Washington State initiative was quickly followed by a similar referendum in California. However, the

majority of voters in both states refused to support the proposed measures. Oregon became the first state to endorse the legalization of physician-assisted suicide, with the passing of the Death With Dignity Act in 1994.

At the same time that right-to-die advocates were making organized efforts to legalize assisted suicide in several states, Jack Kevorkian, a Michigan medical pathologist, announced that he had assisted in the death of a middle-aged woman diagnosed with Alzheimer's disease. In this case Kevorkian used a "mercitron," a suicide machine he had created, to allow the self-administration of a lethal mixture of drugs. Between 1990 and 1998, Kevorkian publicly advertised his aid-in-dying services and eventually assisted in the death of at least 93 patients. Despite existing evidence, Michigan courts acquitted Kevorkian of charges for assisted suicide and murder on three occasions. Finally, in 1999 Kevorkian was found guilty of second-degree murder after performing euthanasia on a 52-year-old man with Lou Gehrig's disease.

While Kevorkian's radical approach to assisted dying was causing considerable social and legal debate, another medical professional, Timothy Quill, went public about his involvement with assisted suicide. In 1991, Quill published an article describing his assistance in the suicide of "Diane," a terminally ill patient with leukemia. Quill had been Diane's attending physician for 8 years and was aware of her values of personal autonomy. When asked to assist in controlling the circumstances of Diane's death, Quill discussed alternatives with her, such as palliative care and aggressive pain management, but each method was rejected as inconsistent with the patient's desire to maintain dignity and control. Eventually Quill agreed, providing Diane with a prescription for a lethal dose of barbiturates. Three months later, after experiencing periods of severe pain and physical deterioration, Diane consumed the medication prescribed by Quill. Quill's admission that he had assisted in the death of his patient received significant attention in the medical community. Although his story did not receive the same level of media coverage as Kevorkian, Quill has become one of the most influential advocates of the right-to-die movement in the medical community.

Kevorkian's and Quill's open statements about assisting in the suicide of terminally ill patients attracted wide public attention to the issue. This focus on assisted suicide was accentuated by two U.S. Supreme Court cases, *Vacco v. Quill* (1997) and *Washington v. Glucksberg* (1997). These cases challenged existing state statutes that criminalized assisted suicide and sought to establish a constitutional right for assisted suicide in the case of terminal illness. The U.S. Supreme Court heard both cases simultaneously but refused to recognize a constitutional right to assistance in dying by suicide. The Court distinguished between refusing medical treatment and providing assisted suicide, supporting patients' rights in the first case but not in the second.

Although the Supreme Court ruling was a defeat for right-to-die activists, it did not foreclose future discussion of end-of-life issues. In a footnote, the Supreme Court specified that it would be open to hear right-to-die cases in the future. In addition, the Supreme Court allowed the states to develop their own laws regarding assisted suicide. Thus, although the Supreme Court refused to grant terminally ill individuals a constitutional right to seek assisted suicide, it did not prevent the states from making their own decisions on the issue.

In the aftermath of these Supreme Court rulings, the right-to-die movement underwent a period of transition. In 1992, Derek Humphry retired from his leadership position in the Hemlock Society, which led to a series of internal organizational changes. In 2003, the society's board of directors voted to change the name of the Hemlock Society to End of Life Choices. In 2005 End of Life Choices and Compassion in Dying merged to form Compassion and Choices. The stated goal of the new organization is to promote legislative reform and expand patients' options at the end of life, including greater access to palliative care, adequate pain control, and the legalization of assisted suicide.

Although the right-to-die movement in the United States has changed in recent years, its accomplishments are clear. Court cases, such as *In re Quinlan*, established patients' rights to refuse life-support interventions and to enact advance directives. State referenda gave Americans the choice to support or oppose the legalization of aid-in-dying, and Oregon became the first state to allow physician-assisted suicide under strict regulations. Medical professionals made public

announcements about their involvement with physician-assisted suicide, and the U.S. Supreme Court debated the existence of a constitutional right for assisted suicide.

In conclusion, the history of the right-to-die movement in the United States is a narrative of both progress and challenge. In 2004, Derek Humphry reflected on the accomplishments and the future of the movement. He noted the movement's successes; however, he stressed the need for continued legislation efforts, as well as enlisting greater support from the medical community and society at large. Furthermore, Humphry advocated for eliminating the taboo surrounding assisted suicide by integrating right-to-die issues in the social and moral fabric of American culture.

School Shootings

School shootings are defined as events wherein a person or multiple individuals use gun violence to wound or murder members within an educational institution. These shootings are committed by a variety of people who may be either suffering from a mental illness, who are disenfranchised, current or former students, members of the staff or faculty, or outsiders in the community. There may be prior experiences of bullying or discrimination toward the shooters. The shooters end up killing or wounding their victims and often, in the end, shooting themselves. Shootings that have more than 10 victims are characterized as massacres or acts of terrorism.

History

Violence has been a part of schools as long as there have been such institutions. In the 17th century, European children routinely went to school armed with swords and guns. In the 18th century there were violent uprisings and rebellions by university students who turned their violence toward those in authority.

In 1764, the Enoch Brown school massacre was notorious because of the type of violence involved. Four Lenape American Indian warriors entered a schoolhouse where Enoch Brown, the schoolmaster, and 12 students were working. He pleaded with the warriors to leave the children alone, but they shot and scalped him and tomahawked and scalped the children. Two of the scalped children reportedly survived. Violence was initially directed toward the teachers or masters within a school, but by the 20th century the focus of the aggression began to change as students began to target other students.

Violence and shootings before the 1990s occurred most often in large urban areas; however, school shootings in the 1990s occurred in largely suburban, white, middle-class neighborhoods. The most notorious and widely publicized school massacre occurred at Columbine High School in Littleton, Colorado, on April 20, 1999. It was here that Eric Harris and Dylan Klebold, two students at the high school, brought explosives and guns into the high school and began their killing spree. They were attempting to kill hundreds with their explosives and when that didn't work, they went on a shooting rampage that resulted in the death of 12 students and a teacher; 24 others were wounded, and they killed themselves. This was the school shooting that changed policies and procedures in high schools throughout the world.

Cultural Considerations

Worldwide there are families in which work, divorce, economic situations, and the challenges of single parent homes leave children alone much of the time. Many analysts believe this condition has created an environment that fosters a culture of isolation and disconnection in those children. Many of the students who participate in school shootings spend an inordinate amount of time home alone, and it is believed that they become

shaped by the culture of the media that they and their peer groups participate in, namely television, the Internet, and violent video games. It is also suggested that violent video games may be linked to an increase in aggression among these young individuals and, in many cases, may lead to their being desensitized to violence.

Along with isolation there are issues of an abusive family situation that breeds fear and rage. Adolescents who have suffered abuse or humiliation, or students who have emotional disturbances and who spend their time alone, may choose to engage in dangerous activities to express their frustration and anger. Religion and politics may also be a factor in some countries.

In the United States, a third of all households have at least one gun, and many of the shooters involved in school shootings access their weapons from the home. Almost all of the shooters have had prior experience with firearms or have gotten the weapons used in the violent events from their own homes. The effects of graphic and gratuitous violence in video games and violence in the media seems to influence some boys in particular, associating blood and violence with winning. Many of the social pressures these children experience affect their sense of self-worth and lead them to identify themselves as victims. In turn, it is suggested the students tend to focus their internal rage outward onto others.

Identifying Factors

Effort is directed toward identifying those factors that lead school-age children and young adults to engage in such school shootings and related violent activities. At issue is the identity of the common characteristics of these individuals, and what social policies and procedures can be implemented to assist in identifying potential perpetrators of school violence. Such concerns generate a list of questions, including whether these violent individuals are genetically predisposed to this type of behavior, whether they are physiologically impaired or they are spiritually and psychologically unfit, whether those children and young adults who have already engaged in school violence are examples of ineffective and damaging parenting styles, and whether or not abuse, bullying, and the resulting isolation were cause for a dangerous disconnect from other human beings. Although there do not appear to be any clear answers currently available to assist in addressing these issues in the public domain, there is a sense that all of these may be elements that lead to these violent expressions of the rage, frustration, despair, and hopelessness that, in turn, are carried out through these horrific acts of violence. The U.S. Secret Service suggests that adults ask the following questions to avoid school shooting: What is the child saying or what has the child said? Do they have complaints? What do their friends have to say? Can they get a gun or guns? Are they suffering from depression?

Although there isn't a profile, there is a stereotype of a student who is considered to be more likely to become a perpetrator of a school shooting. White males who dress in black clothing and long black trench coats who are socially isolated and are disengaged in their academic communities serve as an example. These young boys and men spend their free time alone playing violent video games, browsing the Internet, and are often suicidal.

In trying to establish a profile of possible perpetrators of school violence, it is important to rise above the existence of the myths surrounding those who are most likely to commit school shootings. Researchers report that at present there is no accurate profile that can be used to identify a student or groups of students who will be likely to participate in school shootings. There are a variety of family structures, ethnicities, academic achievements, personalities, and school histories that influence the lives of the shooters. These factors range from seemingly stable, intact families from the middle to upper socioeconomic strata of society with students who are social and who perform well academically, to students who come from low socioeconomic households who are socially isolated and inept individuals who are less than successful in the academic environment. Students who commit these crimes are identified as being from all socioeconomic backgrounds.

It is also believed by some analysts that school shootings represent impulsive acts that are spontaneous without planning or forethought. However, events such as school shootings do require planning and gathering of weapons. One myth that has been dispelled is that no one around the shooters knew what was being planned. In almost every event, there were others who knew about previous behaviors, conversations, writings, or postings on the Internet that indicated or foreshadowed the events that would follow. Many of the adolescents had peers who knew what the shooters were thinking and planning before the shootings.

There are no clear defining characteristics except for the common denominators that are identified as a sense of isolation and a lack of social integration leading, in turn, to an erosion of self-esteem and self-worth among many of the shooters. In some instances, they feel unfairly treated by others and are not satisfied with the way in which they lead their lives. This outlook can lead to depression, and in many instances, instead of the anger being focused inward it is focused outward toward others. But because there is no clearly defined profile, school shooters are also thought to be intelligent, capable, social, and likable people who do not fit the stereotype. Many school shooters, however, did have prior experiences with bullying and aggression. Much of the bullying centered on the shooters' masculinity, which leads to the one common factor among almost all shooters: gender. White boys are the shooters. Why boys and not girls seems to stem from the intractable gender difference around violence. Boys see violence as a legitimate way to resolve conflicts and its actual use. Girls often lose their voice when confronted with trauma or violence, where boys can gain a voice around false bravado, risk taking, and gratuitous violence, which some have called the "boy code."

Risk Factors

In September 2000, the Federal Bureau of Investigation compiled a list of risk factors at the conclusion of a two-year study of school shootings. Traits they identified included poor coping skills, inappropriate humor, alienation, signs of depression, drug and alcohol abuse, narcissism, access to weapons, and no limits to, or monitoring of, television and Internet use by the shooters. In the same report there is a discussion of attending to clues of a student's personality that may come from seeing how a student copes with conflict, disappointments, insults, and other stressors that may occur in the student's life. How they express anger, frustration, and sadness can also be clues. Some predictors of a person who may engage in this violent behavior would be if a student can or can't empathize with others, sees others as inferior, has disdain for others, dehumanizes others, or has an exaggerated sense of entitlement. They may externalize blame, exhibit anger management problems and intolerance, have a lack of trust, and may look to manipulate rather than relate to others.

Three dynamics are identified: the school dynamics, the social dynamics, and the family dynamics. Professionals need to pay close attention to schools and students to search for clues to how the environment can help create a culture that breeds this type of violence. There is no one indicator that will appropriately identify or profile a shooter, but they can be identified if there are professionals who are attending to the whole person, including their family history and the school environment of the students with which they work.

School dynamics play an important part of the equation in determining why a shooting would happen on the campus. Factors that have contributed to creating a culture where this kind of violence occurs include a tolerance for bullying. Officials may be oblivious to it or intervene only selectively. The school may promote or maintain inequitable class or race divisions. There is often a "code of silence" among students with little trust of the adults in the community.

After the Columbine High School shooting that occurred in Littleton, Colorado, in 1999, schools around the world began to address what became known as the serious issues of bullying and aggression in high schools and universities. What educators now recognize is that there are long-term effects that result from bullying, including anxiety, depression, and suicidal ideations. In order for violence to come out of these experiences, there has to be a target and motive for violence, a way to commit the violent act and a means to do it. In contemporary society, violence is expressed as a form of entertainment that is glorified in almost every type of media children experience. Such experiences can lead to a condition of desensitization of the effects of actual violence and hate, and distort the perceptions of shooters. Violence is believed to be a learned behavior, and coupled with relatively easy access to firearms, violence becomes deadly. These factors brought together can lead to a school shooting.

In the case of some school shooters, a pre-existing mental disorder may operate as the stimulus for the acts of violence. In the case of Eric Harris, one of the Columbine shooters, he was found to be a psychopath. Psychopaths are aware of what they are doing but have the capacity to rationalize their actions. They have no conscience, view themselves as superior to others, and lack empathy or remorse for their behavior.

Impact of School Shootings

A political effect has evolved as a result of school shootings. That is, many people are demanding clearer and stronger gun control laws. There are many who are opposed to stricter gun control laws. People believe that if students could carry concealed weapons they might be able to stop a shooting incident either from occurring at all or at least minimize the loss of human life. Fear of school shootings is a consideration of school officials from the elementary institution to college and university campuses around the world. There has been a call for a comprehensive violence prevention plan where there is an informed judgment on assessing threats within a school without overreacting and unfairly stigmatizing or punishing those who are not dangerous.

After the Columbine High School and the Virginia Tech University shootings, schools have begun to address the issues of bullying and violence on school campuses by adopting and implementing peer mediation and counseling services alongside antibullying campaigns. There are metal detectors

and resource officers at many schools and teacher training on how to attend to the clues previously mentioned. Communication systems and emergency response procedures have been improved. Teachers and administrators are being trained as first responders in the event of a shooting to keep students safe or care for injured students. Technology is being embraced and a new system called Rave will alert students by text messages on their phones to warn them of danger. Threat assessment teams are being used on high school and college campuses. This team is a multidisciplinary unit that determines an appropriate response to a threatening statement or writing. The idea is how to help the individual by identifying the available resources. On college campuses there is a more stringent screening process for students.

The Future

Many suggestions are proffered on how to prevent school shooting in the future, including a proposal to permit teachers and administrators to have access to firearms. Another proposed solution is to train students to respond in a school shooting situation. In this form of training, students would learn how to immediately react to an assailant with any item that is available. But this is based on the assumption that if enough students responded, they would be able to overwhelm and subdue a gunman. Another issue that people believe should be legislated is making it a crime for a child to have unsupervised access to guns and, if a person buys a gun, they should take reasonable precautions to store firearms away from children.

One unintended consequence of school shootings and the social stereotypes that have emerged from these events is the long-term affect of fear and mistrust of people who are different and who might fit the stereotype of a school shooter. This consequence has generated a focus on teaching tolerance and conflict resolution to help ameliorate the conditions that may lead someone to experience a sense of hopelessness and disenfranchisement as a result of their school experiences.

School shootings have changed the culture we live in because these events are thought to represent a common occurrence. Although this fear is prevalent and contrary to the myths that have evolved from those school shootings that have occurred, school shootings are actually quite rare. Despite this social fact, in the years following the Columbine High School shootings, there has been an incredible amount of research conducted and books written in which the analysts attempt to identify what can be done to reduce the possibilities that such events will happen again. There is a concerted effort by school communities to pay close attention to the people in those communities and hopefully identify and provide support to the individuals who need it.

Second Burial

Second burial terminates the cycle of mortuary rites that follow first burial. Between the first and the second burials, there is an intermediary period that coincides with the duration of decomposition of the corpse. After exhumation, the bones are collected, sorted, and ritually cleansed, and then moved to a

new location. This can either be an individual grave, a common grave, or an ossuary. There is great cross-cultural variability in the traditions of second burial. Examples of second burial can be found in Asia (e.g., Kalimantan, China, Japan, Taiwan), Africa (e.g., Mali and Madagascar), Australia, and in Europe (e.g., Greece, France, Austria, Switzerland, the Netherlands). Second burial does not necessarily involve exhumation. Second mortuary rites can also be performed with a substitute for the body, but the body typically accompanies the relocation of the site of worship or honoring of the dead. In most cases, the second burial is considered final, but tertiary burials do occur. When the second burial specifically entails the removal and reburial of the corpse, it is called the secondary burial. Next to secondary burial, other forms of secondary disposal exist, as the body can also be cremated or displayed after an initial period of burial.

Research on Second Burial and Its History

Robert Hertz was the first scholar who investigated secondary rites of disposal. In 1907, he described the secondary treatment of human remains by the Dayak in Borneo and keenly observed the regular and socially sanctioned relocation of relics of some or all of the deceased from a temporary to a permanent grave. Hertz's analysis of the second burial drew attention to mortuary rites as indicating a transition rather than a termination. Hertz argued that, among the Dayak, the body cannot immediately be taken to its final resting place; instead, this transition can only be made after an intermediary period, during which the body is placed in a temporary shelter. Across different cultures, depending on the method of disposal, the intermediary period varies from 40 days to 15 years—lasting minimally until the bones have become dry. Especially important in this process are notions of impurity, pollution, and purification. The soul of the deceased is feared by the living because, until complete decomposition of the corpse, a soul is considered to remain on earth and capable of inflicting harm upon the living.

Parallel to the transformation of the decaying corpse, the soul of the deceased must pass through a liminal phase before receiving its final destination. The Dayak believe that only after the second burial will the soul enter the land of the dead. Hertz's analysis of the second burial demonstrates how the fate of the corpse and the soul are interlinked. Furthermore, it shows the impact of the death on the deceased's social environment. After the death, the intermediary period provides the mourners with the time needed to come to terms with personal loss. Like the dead, the living undergo a liminal phase, during which their identity is adjusted. Through enacting the final passage, not only is the soul transferred to the land of the dead, but the rites of the second burial also restore the "normal" social fabric among the living.

Thus, second burial concerns both the transitional status of the living and the dead; it is a passage in which the living, the soul, and the body progress from one state into another. The second burial is best understood as part of a series of accumulative death rites that take the living through various mourning phases according to the way they perceive the condition of the deceased.

Finally, critics of Hertz claim that the timing in second burial is also related to economic factors. They argue that the intermediary period is also needed to collect money and materials for the second burial, and that secondary burial rites vary along with social status. Notwithstanding the critics, Hertz's account of secondary burial rites provided us with an instrument to analyze mortuary rites as part of a tripartite process in which the corpse, the soul, and the mourners are interlinked.

Second Burials in Asia

Typical examples of secondary burial are seen in the southern provinces of China (e.g., Fukien, Kwangtung, Hong Kong, Taiwan). During the initial stage, the deceased is buried in a coffin at a temporary grave. Secondary burial takes place after 7 to 10 years. The coffin is exhumed and the bones are collected in a ceramic pot and finally reburied in a permanent tomb alongside their collective ancestors. Chinese secondary burial is based on the concept of yin and yang. For the Chinese, flesh is inherited from the mother and is yin, in essence, while bones are passed on from the father and are yang, in essence. The bones are retained and worshiped, as they are considered pure, whereas the flesh, which is impure, is the source of death pollution and must be completely removed by decomposition. The preservation of bones is

paramount in maintaining the realm of the ancestors as the continuation of the pure male line.

Second burials were common in the southern part of Japan. Japanese folklorists analyze these second burials as part of a "double-grave system" (*ryōbosei*) in which the burial grave and the ceremonial grave are separated. Japanese second burials are different from Chinese secondary burials; they do not include the exhumation and reburial of the dead at the second burial site. In Japanese second burials, the corpse is permanently interred at a collective community burial site, while the ceremonial grave is a monument honoring the household's collective ancestors. After 49 days, when the period of mourning ends, the bereaved no longer visit the burial site, but instead utilize the household ceremonial site for ancestor worship. Japanese folklorists have debated its historical origins and the reasons behind the double-grave system, but have not reached a consensus. They are in agreement, however, that second burial links Japanese perception of the afterlife, purity, and pollution. The ceremonial grave ensures the transformation of the deceased into a purified ancestral spirit and an agricultural deity, who in turn blesses the household and its community. This is central to the well-being of the household and community. After World War II, the practice gradually ceased due to modernization, urbanization, and the commercialization of death rituals, and was replaced by the practice of a single grave as in the rest of Japan.

Second Burials in Europe

In secondary burial rites in Greece, women have an important role in burying, exhuming, and reburying the dead. After three to seven years, the bones are exhumed, formally putting an end to the period of mourning. After a priest's blessing, the deceased is exhumed by the next of kin. The bones are carefully collected, washed, rinsed with vinegar or Greek wine, and left to dry in the sun. Thereafter, the bones are carefully sorted and gathered in a box in which the skull is placed on top. By segregating the wet remains of the flesh from the dry, purified bones, the corpse is ritually transformed and the deceased's passage into the otherworld is facilitated. It is believed that the bones of a sinful person will be covered with hair and flesh. Only if the bones are clean and white at exhumation has the soul completed its journey. Finally, the bone box is placed in the local ossuary. However, this does not necessarily mean that the deceased is depersonalized, because the family continues to care for the bone boxes of their relatives in the ossuary by bringing flowers, candles, or photographs.

Secondary treatment of human remains is also common in other parts of Europe. Even though second burial is mostly mentioned in the case of repatriation of war dead or alongside examples of famous people, such as Ludwig von Beethoven, up until the 19th century, second burial took place throughout Europe. In countries including Austria, England, France, Germany, Italy, and Switzerland, bones and skulls were exhumed and received a second burial in an ossuary. In Hallstatt, Austria, the oldest bones in the churchyard were exhumed every 10 or 15 years. After that the skulls were cleaned, bleached, and painted by the bereaved. Some survivors painted a cross, a flower, the deceased's name, and sometimes even inscribed the cause of death on the skull. This tradition is only infrequently practiced today.

In the Netherlands, a new death rite is emerging after the funeral that was previously considered the final death rite. Since the early 1990s, ashes are increasingly taken home after cremation and sometimes processed in mourning relics, creating a longer prolonged period of ritualization. While the positioning of the ashes used to be in the hands of crematory personnel, more commonly nowadays, next of kin scatter or place the ashes themselves while reading out a poem or placing flowers.

The same accounts for burials. In the Netherlands, grave rights are bought for approximately 10 to 20 years, ensuring full decomposition of the corpse. Thereafter, the next of kin can either prolong or relinquish these rights or as a third choice, opt for second burial, executed by professional gravediggers. Secondary disposal occurs for three main reasons: first, to reunite deceased family members that are buried separately; second, to reduce travel after the bereaved move; and finally, to revise the choice of burial and opt for secondary cremation instead.

Generally, in second burial the corpse is ritually purified from death pollution through separating the flesh from the bones. The transformation of the corpse corresponds with a passage of the

deceased into the realm of the dead. While the mourners re-encounter the dead and give the transformed corpse a new place to rest, the relationship between the living and the dead is reconfigured into one of harmony. In contrast with these examples, the new practice of secondary burial in the Netherlands is not so much about the transformation of the corpse and transition of the soul as about changes in the living situation of the bereaved affecting the arrangement of the deceased.

Serial Murder

Beginning in the 1880s and for the next 100 years, the phenomenon of multiple murders attributed to one individual was referred to as "lust murder," and, although the term "serial murder" was first coined in the latter half of the 20th century, the media confused serial murder with mass murder, referring to the latter term until the end of the 1980s. As more instances of sequential homicide were officially recorded throughout the first half of the 20th century, informed explanations of serial murder were developed during the 1960s and 1970s by government analysts interested in the nature of such "multicide." By the 1980s, scholarly literature also had been developed. Much of this research was conducted in Australia, Great Britain, Germany, and the United States and is complemented by the FBI Supplementary Homicide Reports (SHR), which provides an incidence-based compilation of homicide victims and offender sociodemographic data.

Accordingly, six kinds of murders are identified, namely: single, double, triple, mass, spree, and serial. The multiple-homicide concept includes two of these six classifications, serial murder and mass murder, thereby providing an important operational distinction. Articulated by James Alan Fox and Jack Levin, the multiple-homicide concept is defined as the murder of at least four victims. By establishing this minimum body count, multiple killing is distinguished from homicide generally. This conceptualization further differentiates the forms of multiple homicide, namely, those cases in which victims are slain at once (the mass murderer), over a short period of time (the spree killer), or over an extended period of time, which distinguishes the serial murderer concept.

Defining Serial Murder

The FBI's *Crime Classification Manual* provides a concise, albeit controversial, definition of serial murder as, "Three of more separate events in

three or more separate locations with an emotional cooling-off period between homicides." Thus, several definitions of serial murder have been advanced. Among these are those events we now refer to as serial murders but were once identified as "stranger murders." This phenomenon was also referred to as chain murder, mass murder, and, later, multicide. Introduced into the literature in 1972, the term *multicide* characterized an act by an individual with a psychopathological personality who committed a number of murders over an extended period of time.

Even the origination of the term *serial murder* is itself in dispute. Once thought to be used for the first time in 1982 by an FBI agent, there is evidence that the term was actually created in 1966 by the British author John Brophy in a book titled *The Meaning of Murder.* The term *serial murder* is again found in the literature based on the work of forensic psychiatrist Donald Lunde, whose book, *Murder and Madness,* was published in 1976.

Although serial murder varies widely by geography, countries such as Australia, Germany, and Great Britain rarely record serial killing events. It is estimated that 80% of all known serial murderers identified during the 20th century resided within the North American continent, especially in the United States. Despite the claim, serial murder is not a new crime wave that began in the 1960s. Placing the available data within an appropriate social and historical context offers the insight that within the United States, the multiple killings were at least as prevalent during the1920s and 1930s as they have been since 1965.

During the 100-year period from 1900 to 1999, there were 1,246 serial killers officially documented worldwide and, despite these estimates, only 236 are known to have resided within the United States. Of the estimated 18,361 murder victims worldwide, a total of 3,313 were murdered in the United States. During the period from 1920 to 1940, Germany reported a dozen cases of serial killing in which over 20 victims were claimed for each case. Given that this kind of serial murderer activity was not documented in that country prior to or since that time period leads to speculation as whether the cause of this high number of deaths may be attributed to politically motivated murder.

In Australia, 5% of all homicide events involve multiple victims, but, on average, only 1 multiple homicide is recorded annually. England and Wales record few cases of serial murder. For the period of 1940 to 1985, only 12 cases were recorded in England, with a victim count that ranges from 4 to 26. For the 46-year period, these 12 cases accounted for a known total of 107 murders; prostitutes (n = 24) represented the largest group of victims.

Serial killers are generally young and engage in a childhood pattern of violence that is directed toward animals and other humans, young and old alike. Approximately 26% commit their first murder while still in their teens, 44% began to kill when in their 20s, another 24% do so in their 30s, and about 4% in their 40s.

Approximately 13% of known serial killings committed within the United States involve multiple killers. Of this total, 56% involve 2 killers, especially 2 females, with the remaining 44% involving groups that vary in size from 3 killers to cults with many members. A variety of pairings are involved among multiple killers, but the most usual grouping involves all females ranging in size from two to a large number of females as characterized by the "angel makers" of Nagyrev, Hungary, who, during the 1920s, murdered their husbands, and the "angels of death" medical murders committed during the 1980s by female personnel at the Lainz General Hospital in Vienna, Austria.

But serial killers are more commonly white males between the ages of 25 and 35 who kill white females. The murder usually occurs in areas of high transience and population change, involves people of similar status, and usually involves the killing of a total stranger, including prostitutes, drug addicts, homeless people, and teenage runaways—people on the fringe of society who hold little community status or attachment.

Historical Relevance of the Serial Murder Concept

Serial murder can be traced to ancient Rome and attributed to Locusta, a female who poisoned her victims. Locusta was executed for her crimes in Rome during 69 C.E.

Throughout the Middle Ages, examples of both male and female serial murderers are noted, including cases involving the bizarre, perverted sex and magic rituals, and other sadistic behavior in which the lives of perhaps 100 children were taken by the

French baron Gilles de Rais. Identified as exhibiting an unhealthy appetite for young children, the Baron was executed in 1440, as were several servants who had procured the unwitting young for the baron's sadistic pleasure.

From the Middle Ages and until the latter portion of the past millennium, poison was the killers' method of choice. And during this period, women were often counted among the worst of the serial killers. Notable examples include a number of females known to have poisoned upwards of 600 people. Some killings involved cannibalism, as children were murdered and then fed to starving family members.

Torture and killing for pleasure well served the needs of Erzebet Bathory, a Hungarian born in 1560. Of noble heritage, her family members included many high-ranking government and church officials. This young serial killer began inflicting torture during her late teenage years upon even younger servants and later village peasants. Tried in 1611 for an alleged 80 murders, it is estimated that Erzebet tortured and killed 300 to 650 victims.

Such examples became more bountiful as the Industrial Revolution took effect, and over time the profile of serial killers also changed. While during the Middle Ages aristocrats preyed upon the peasant class to satisfy their depravity, during the Industrial Revolution members of an expanding middle class killed street prostitutes and homeless children, as well as household employees. In contemporary society, serial murderers are generally from the blue-collar working and lower-middle strata.

Serial Murder: An Emerging Concept

Until multiple homicide was defined in contrast to homicide in general, many deaths that could be attributed to serial murderers were not officially documented. Outside of the church recording of births, marriages, and death, the recording procedures of the Middle Ages were not well orchestrated. Such organization was finally established under the directives of the "moral statisticians" during the early 1800s. One general area of interest for these moralistic but scientifically oriented individuals was crime. Thus, as the process of recording important events became an official government act, more specific information regarding episodes involving suspected serial killings began to emerge.

While official data pertaining to historical serial killing remain sparse, the opposite is now true. In the United States, more than 50 individuals are known to have taken the lives of from 5 to more than 100 victims between the early 1900s to the end of the 20th century. The number of the victims in the United States alone is estimated to be between 3,500 to 6,000 victims annually. In contrast, in the period 1960 to the late 1990s, Australia recorded only nine serial killers. In England, during the 1940 to 1985 period, a total of 12 such cases were recorded.

Many serial killers remain unidentified, and their legacy has grown to the status of urban legends. Classic examples include the Jack the Ripper killings in several districts of London, England, that occurred during the year 1888 and the Axeman of New Orleans, who was thought to have been operating in that city during the 1918 to 1919 period. Then there is the Zodiac killer, who stalked victims in the northern California area during the 1970s and 1980s.

The first known American serial murderer can be traced to the 1880s, when Herman Webster Mudgett killed 27 women. Many of America's most famous serial killers (e.g., William Bonner a.k.a. Billy the Kid) also have been the most prolific, but the scope of their criminality became lost in time as their names and actions merged to become part of the legend of settling the U.S. Western frontier. But this was to change beginning with the 1950s and lasting through the final half of the 20th century. During this period, many more serial killers were identified, including Austria's international murderer Jack Underberger.

The early portion of the modern era produced few documented instances of serial killing, but these became high-profile events. During the first 4 decades of the 20th century, serial murderers received great public attention and their reputation was enhanced in part by the descriptors employed by the media. Terms such as blue beard, black widow, strangle psycho, viciously depraved, mad butcher, backpacker serial killer, lonely hearts killer, torso killer, cannibalistic pedophile, the gorilla killer, and homicidal burglar have all been used to describe both the known and unknown serial killers of this period. During the 1920s, two serial killers of note emerged, namely Earle Leonard Nelson and Carl Panzram, while the decades of the

1930s and 1940s produced Albert Fish, Jack Bird (who confessed to a dozen murders), and William Heirens.

Although females do not receive much recognition, a large portion of the serial murder population is female. For the period of 1800 to 1986, it is reported that of the serial killers identified, approximately 14% were female. Recent critical analysis of the sudden infant death syndrome (SIDS) phenomenon also suggests that many cases of SIDS may cover for the serial murder of infants committed by the mother, either because of the insurance profit motive or because of some unusual urge or compulsion.

Sexual Predation

Of the limited number of research case studies that have been conducted, the sexual homicide type receives the most attention; two-thirds of the serial killers are sexually motivated toward involvement with their victims. It is also noteworthy that the majority of serial killers were not or are not homosexual but, of those who were, many can be counted among the most prolific serial killers.

Analysts of multiple murder pose that while the motivation and patterns of serial killers differ, the most prominent form of serial killing is the power-hungry sadist, who seeks to gratify their sexual fantasies. More than objects of sexual attraction, serial killers view their victims as aesthetically pleasing and a source of companionship. Even when dead, the perpetrator may engage the victim in various forms of abnormal activity, including the use of photographs or recordings, pornography, and engaging in acts of rape, torture, sadomasochism, voyeurism, and lust murder or sadistic brutality, including the mutilation of body parts, especially the genitalia.

Types and Motives of Serial Murderer

There are three types of serial murderers. Nomadic killers move from city to city and state to state. The most common, territorial killers, stalk their victims within certain areas. Currently insights are being brought to bear on the stationary serial murderer, an emergent type of killer who is far removed from the violence and death of the streets and private residences perpetrated by the nomadic or territorial serial killer types. The rarest form of serial murder, the stationary killer, is employed within professional workplace settings that are arenas of public trust, such as hospitals, nursing homes, or rest homes, as well as transient and permanent residential locations.

Also committed in a workplace setting, medical murders, dubbed "mercy killings," committed by physicians, nurses and their aides, hospital orderlies, and dentists, have produced the supposed "hero type" perpetrator. Having created a life-threatening situation, the hero then attempts to save the patient. These kinds of multiple homicides also include the motive of profit (insurance claim) and the sexual motive, such as medicating and then sexually molesting patients. Other workplace killings perpetrated by employees take place in motels and apartments.

Other efforts to classify types of serial killers led to the development of (a) the visionary serial killer (responds to voices or visions that demand certain people be destroyed), (b) the mission-oriented serial killer (destroy evil people because they debase society), (c) the power/control-oriented serial killer (derives satisfaction from having the power to determine the fate of the victim, including sexual arousal), and (d) the hedonistic serial killer. The hedonistic serial murder category is a composite of two subtypes, namely the hedonist, oriented toward pleasure and/or thrill seeking, and the lust killer, who is sexually aroused. Described as a sociopath whose ultimate goals include power and sexual satisfaction, the lust killer seeks to ravage the victim and may even derive more pleasure through postmortem sexual activity.

As noted in the FBI *Crime Classification Manual,* 4 general motive categories include 32 subcategories, each of which can be applied to one or more cases of serial murder. The general categories of motives for serial murder are criminal-enterprise homicide (with 10 subheadings listed), personal-cause homicide (with 11 subheadings), sexual homicide (two-thirds of serial murders are related to this form), and group-case homicide (the 3 subtypes are cult, extremist, and group-excitement murder).

Serial Killers and the General Population

Evidence that psychiatric disorders are more prevalent among serial murderers than the general U.S. population is not strong. In Europe, however,

where serial killing is much less frequent than in the United States, serial murderers are diagnosed as mentally disturbed. What may prove useful to our understanding of whatever differences do exist is based on the hypothesis that most normal people are usually capable of controlling or channeling their aggressive impulses outward toward objects other than humans and animals.

The more common characteristics identified in the international research literature include growing up in a dysfunctional household, a history of poverty and unemployment, a pattern of heavy drinking, a preoccupation with fantasy and murder, and learning to associate violence with pleasure. That these characteristics eventually may lead to the emergence of a serial killer depends on whether such individuals are influenced by higher than normal instigation to aggression and lower than normal inhibitions against aggression that are characteristic of the psychopath and sociopath.

And there is a growing literature that depicts serial murderers as primary psychopaths, secondary psychopaths, overcontrolled (excessive oversight) and undercontrolled (a lack of supervision and guidance), paranoid schizophrenics, and pathologic sexual sadists with histories of childhood physical and mental abuse. Recent findings suggest that 10% of male serial killers may be paranoid schizophrenics, while biological findings indicate brain damage to the prefrontal cortex region may explain some cases. To further enhance this position, some cases of delusional psychotic and paranoid schizophrenics with multiple personality disorder have been cited. Despite these strong characterizations, there does not appear to be sufficient evidence to confirm that the serial murderer is more disturbed or defective, nor do they experience more traumatic childhood life events than are found among the general population.

Sex and Death

An exploration of the contradictory functions of death and sex indicates the existence of several biological dimensions, including the evolution of sex itself, excess mortality of males, reproductive differences that relate to survival, health benefits of sex, and negative health risks associated with sex. In addition, there are cultural elements, such as survival after spousal death, "terror sex" as a coping mechanism to interpersonal threats, sex after physical death, reproduction after death, and concepts related to sex in the afterlife. Although it is difficult to state with certainty that the relationship between sex and death is causal, casual, or coincidental, Thomas Lynch, a contemporary American funeral director and author, suggests that both sex and death leave you wide-eyed, out of breath, are horizontal mysteries, and both are over before you know it. In the following entry, the intersection, interrelationship, and independence of sex and

death in light of evolving cultural, technical, and biological myths and realities are explored.

Evolution of Sex and Death

In 2006, *The New Scientist* published a list titled "Top 10: Life's Greatest Inventions"; sex and death were ranked 6 and 7 on that list. From a biological perspective, sex requires sacrifice in terms of effort, energy, time, risk of injury, and the risk of not finding a mate. But above all, sexual reproduction requires that an individual reduce their contribution to a subsequent generation by half, compared with those who reproduce by cloning or through asexual means. However, regardless of the evolutionary payoff for sexual reproduction, one outcome is most important, namely, it is only with the evolution of sex that death becomes inevitable. Single-celled organisms that reproduced asexually were essentially immortal because exact copies of themselves survived over time. Death, from this perspective, is necessary because of sex.

In human communities, there is a significant sexual divide to mortality and morbidity. The fact that in developed societies, females outlive males by five years on average has significant demographic, biological, and social consequences. The sex of an individual is the most important demographic factor that predicts early mortality. Males may be greater risk takers, but simple risk taking does not fully explain all the mortality differences between males and females. Also biologically, male fetuses are significantly more likely than female fetuses to experience complications and death. That same trend continues after birth and leads to differential male mortality rates.

Why Can't a Man Be More Like a Women

A study of eunuchs, males who had been castrated before puberty, showed an exception to the general rule of females outliving males and demonstrated that those eunuchs lived a remarkable 12 years longer, on average, than males with intact testes. Male aggressiveness and competition for reproductive success is partially controlled by the production of the hormone testosterone, a hormone that is produced in the testes and is, thereby, greatly reduced in castrated males. Male reproductive success and aggressive behavior come with a significant price: reduced longevity. Menstruating and pregnant females, on the other hand, produce significant increased amounts of the hormone estrogen that acts to protect the female heart against oxidative damage and age-related telomere attrition. This monthly massive increase in the hormone estrogen has been labeled the "jogging female heart" effect and helps explain a lower incidence of cardiovascular disease in females before menopause. The health advantage to females is significant; males have a mortality rate from cardiovascular risks that is five times higher, and their morbidity is three times higher than comparable-aged females.

Reproductive Senescence and Its Impact on Longevity

Females who have a delayed onset of menopause (or the cessation of egg production) live longer than females who undergo earlier menopause. Those who have menopause before the age of 40 are at twice the death risk when compared to females who do not achieve menopause until after the age of 50. Thus, fecundity at advanced ages, at least among females, is associated with more extended life expectancies. Among males, there is no similar dramatic and rapid climatic cessation of reproductive function comparable to menopause. However, male fertility does exhibit significant variation and change, especially with age. While older male gamete production, unlike that of aging females, tends to be continuous regardless of age, somatic deterioration and increased death risk is a major outcome of male hormonal adjustment for those over 40 years of age.

When Sex Is Good and Engaging

An article in *The New England Journal of Medicine* makes clear that many older adults in the United States are continuing to be sexually active. Although there were some gender differences and problems associated with sex and aging, older women expressed lower desire (43%), difficulty with vaginal lubrication (39%), and inability to climax (34%), while older men reported erectile difficulties as their most prevalent issue (37%). The frequency of sex did not decline significantly until

after age 74, despite the existence of the problems outlined. In a different study, it has been suggested that the mortality risk was 50% lower in the group with high orgasmic frequency than in the group with low orgasmic frequency. There is further evidence that people who recently had penile-vaginal intercourse had a more positive blood pressure reactivity than individuals who either had a different type of sexual interaction or masturbated, or those who had no sexual encounters. Also, there is the suggestion that semen or properties that it contains have antidepressant benefits for females. In historical settings, whether it is a reading of the *Kama Sutra* or Daoist writings, the message is that an active sex life translates into a healthier and longer life, at least for males. In a recent study, it has been suggested that the frequency of ejaculation is associated with reduced risks for prostate cancer. Even among middle-age males there is strong evidence that sex has a positive benefit for reduced likelihood of strokes and coronary events.

Examples of Sex in Association With Death

According to some cardiologists, a majority of the cases of sudden death during sexual activity involves individuals who were taking part in extra-pair copulations. This is similar to the Japanese term *Fukojoshi*, meaning "death on the stomach." The French term *Le Petit Mort,* or "Little Death," is the description of a sudden death in the act of having sex, especially among males.

Marriage Is Beneficial for a Reduction of Death Risks

Marriage appears to promote longevity and both unmarried women and men have significantly higher death rates than their married cohorts. Men who never married were twice as likely to die as married men of the same age (up to the age of 65), and the death risk for women who never married is lower than men's, but their death risk does not decline after age 65. However, following the death of a spouse, there can be a significant excess mortality among the surviving partner for the first six months of bereavement. Additionally, there are higher mortality risks for younger and more highly educated males following a spousal death, and bereavement was found to decrease with age. The risk of suicide among widowed men is more than three times higher than for married men; there is no difference in the suicide rates between married and widowed women.

Sex and Terror

In the aftermath of the destruction of the World Trade Center on September 11, 2001, numerous events occurred that directly reflect on the relationship between sex and death. The phrase to describe the human social reaction to the aftermath of death, fear, and destruction and the largely uncritical seeking out of human physical closeness in a time of uncertainty and death is terror sex. The terror sex concept is grounded in terror management theory (TMT). TMT suggests that death reminders lead to a greater desire for contact and intimacy, to greater perceptions of romantic commitment in relationships, to more willingness to initiate social interaction, to lower rejection or judgment standards, and to a more positive evaluation of interpersonal skills. These reactions have also been documented in other traumatic events, such as among people hiding in air raid shelters during the London Blitz and survivors of the Los Angeles earthquake of 1994.

This desire for closeness in times of death and destruction can lead to an increase in risk-taking behavior. In a time of heightened danger, safer sex guidelines may be less meaningful or important. A study of men who had homosexual sex following 9/11 found that there was an increase in smoking, drug and alcohol use, and in unprotected anal intercourse, especially among men who reported losing a friend on 9/11.

These findings are consistent with those reported by Arnold Toynbee, who many decades ago wrote a short article in which he identified nine ways through which people reconcile themselves with death. One of the nine methods of adjusting and adapting to death was investing one's continuity in life by creating future generations through engaging in reproductive sex.

Sex After Death

The lack of companionship, lost potential to reproduce, and a lack of sexual activity are issues in life, and these concerns are projected to continue

after death. The Chinese tradition of "ghost marriages," or the marriage between two dead individuals, has a long tradition in the Middle Kingdom, and it is making a comeback in modern times. In rural China, the practice of ensuring that husbands and wives share a grave is again an active part of funeral rituals, even if the male died before becoming a "groom." If an adult male dies and is unmarried, his relatives may contract for a bride from among unmarried females who also died. But an important distinction exists between freshly buried potential "wives" and those of long-established gravesites. This distinction is focused on "wet" and "dry," the level and extent of decomposition of the flesh. A premium is paid for fresh or "wet" female corpses, as opposed to "dry goods" or long buried bones.

Pregnancy Following Death

The cryopreservation of spermatozoa (and embryos) and invitro fertilization (IVF), along with strong human emotions about immortality and genetic and family continuity, lead to procreating after death using various newly perfected reproductive assistant techniques. In a recent case in Israel, a court ruled that parents could attempt a posthumous pregnancy with their dead son's five-year-old gametes that were extracted in 2002. The family advertised for volunteers who would be willing to be impregnated with their dead son's sperm. Over 200 women volunteered to help, and a 25-year-old woman was selected for an IVF procedure.

Such cases generate a variety of ethical and legal issues, such as the autonomy and "presumed wishes" of the dead, the exploitation of the dead by medicine and science, and the well-being of any offspring. Recent discussion of the ethics of posthumous semen retrieval and subsequent potential pregnancies indicate that sperm retrieval from the dead should not be honored unless there is documented written evidence that this is what the dead person desired.

Another case involving the competing ethical and legal perspectives to posthumous reproduction took place in California. A man deposited sperm in a sperm bank and then committed suicide. In his will he expressed a desire for his girlfriend to use the sperm to conceive his child after his death. The court ruled that individual autonomy and privacy permitted the decedent's desire as expressed in the will.

Sex in the Afterlife

The issue of sex in the afterlife demonstrates some of the differences in various religious traditions. Mark Twain in "Letters From Earth" proclaimed of Christianity that it was difficult to imagine a heaven that left out sexual intercourse, the one pleasurable activity that exists for all humanity. Twain saw such a heaven as an "intolerable bore."

The beliefs of dynastic Egypt, Islam, or other faiths affirm that sex is something that happens in the afterlife. To demonstrate the evolving nature of technology on culture, cemeteries in China sell paper copies of Viagra that can be burned in honor of the deceased male relatives to ensure they experience better sex in the afterlife.

Sexual Homicide

While a consensus definition of "sexual homicide" is difficult to establish, the individual components are readily understood—"homicide" or death at the hand of another and "sexual" or relating to the act of sex. In combination, the term as used here relates to the overlap of real or implicit act or symbolism linking sexual relations, fantasies, and/or desires with the act of killing another. This can be further partially separated into the purposeful sexual killer and the rapist sexual killer. That the euphoria inherent in climactic intercourse is juxtaposed with the profound grief and shock of sudden death is incongruous. Even more unusual, the study of this crime is perhaps the classification of homicide, which typically does not include sexual homicide as a subcategory. In addition, the sexual element may be effectively concealed or missed by on scene investigators and detectives. Fortunately, the overall incidence is less than 1% of all homicides. This entry addresses issues relating to the victims of sexual homicide and perpetrator profiles and motives. Issues relating to the investigation and research of sexual homicide also are presented.

Characteristics of Sexual Homicide

In general, the victim of sexual homicide is female and the assailant male, with same-race-on-same-race instances the most typical. The demographic data continue to evolve and contra-race attacks, intergender assaults, and even occasional female-on-male crimes are becoming more common. In slightly more than half of the cases, the victim is known to their attacker.

The killer's motivation may range from opportunity to sadism. The seemingly most obvious is the erotophonophile who achieves orgasm coincidental with his victim's death. This may be suggested by the nature of the assault and the extent of the victim's wounds. Often, the victim sustains extensive overkill wounds during the course of more targeted assaults. In the extreme, sex-related homicide, known as lust murder, of which sadism is a significant component, the victim's body also may be mutilated pre- or, more commonly, postmortem. The crime scene tends to vary significantly, depending upon the killer's underlying motivation, represented by two extremes, the organized and disorganized scenes.

Motives for Sexual Homocide

Understanding the motivation that underscores sexual homicide is essential to understanding the crime. As undesired intercourse or rape (real, attempted, or imagined) is integral to sexual homicide, recognizing the driving forces behind the act and hence the type of perpetrator may facilitate the investigation. The difference between rape and sexual homicide is that the assailant-victim interaction varies in the degree of force employed. Rape tends to be part of an overall criminal act. In sexual homicide, a dichotomy exists between the "rape gone bad," ending in an initially unplanned death, and the more disturbing purposeful sexual homicide, where killing tends to be the crime proper. It is important to bear in mind that not all rapists are murderers, but all sexual killers perpetrate homicide.

Types of Rapists

There are four generally accepted broad categories of rapists: power-reassurance/opportunity, power assertive, anger retaliation/danger excitement, and anger excitement/sadistic. The precipitating event and the nature of the sex act determine the category.

The power-reassurance or opportunity rapist is by far the most common, representing more than two-thirds of all rapists. Considered to be the "gentleman" rapist, the perpetrator typically uses intimidation to coerce the victim. An event may start as a burglary; if the killer becomes aroused he may take advantage of the opportunity, believing that "making love" to the victim is his privilege.

The power-assertive rapist represents 25% of all rapists. Believing he is entitled to dominate female "playthings," this individual physically threatens the victim. The motive is sex and control of the victim.

The anger retaliation or danger excitement rapists account for approximately 5% of sexual homicides. These individuals are over-represented in lethal sex-related cases. Violent "women haters," these killers desire to humiliate and physically harm their victims. Hostility toward and degradation of the victim may include defecation and/or urination upon the victim but ejaculation is uncommon.

The least common of all rapists (less than 1%) is the anger excitement or sadistic rapist. This lust killer seeks to harm the victim. Satisfaction is derived from the suffering experienced by the victim. The lust or sexually sadistic killer epitomizes the worst fears associated with this form of homicide. Due to the nature of their desires, these assailants often progress into serial killers. It is estimated that two-thirds of serial killers engage in some form of sexual interplay with the victim, although not all serial killers are sexual killers.

Perpetrator

A purposeful sexual killer (as opposed to the unplanned death during rape) typically shows a progression in behavior, beginning with fantasy and progressing through various paraphilias (such as priapism fetishism, autoeroticism, bondage, sadomasochism, asphyxiaphilia, bestiality, and necrophilia). Eventually, the perpetrator acts out the fantasy by killing. The rapist sexual killer may progress along a similar spectrum, but the paraphilias and sexualization of the act of killing are not nearly as prominent and may not be present at all.

The most common sexual killers direct anger toward women and seek to humiliate (anger retaliation or danger excitement) or totally control (anger excitement or sadistic) their victim. In all instances, the perpetrator is driven by aberrant fantasy in which sex is predominately a mental rather than physical act. In the latter case, the killer thrives on being "god" to their victim—literally controlling whether they live or die.

Sexual killers succeed because they do not appear all that different from the rest of humanity, the major difference being that the purposeful sexual killer is typically a sociopath and without guilt. Their motive for killing is completely internal. The origins of the sex killer are manifold; however, at least three areas are considered significant—psychodynamics (internal conflicts), conditioning (environment/behavior), and internal processing.

The perpetrator is usually a young to middle-age white male, but juvenile offenders have been increasing in numbers, tending to act out their baseline anger during the commission of a crime. One-third of the perpetrators record an IQ level of 120.

Although rare, women can be perpetrators as well as being an accomplice to luring other unsuspecting victims into traps to be raped by others. This subset also appears to be evolving in greater numbers. Likewise, youth gangs may become involved in ritualistic sexual homicides as part of an initiation or other rite of passage within the group.

Misconception

A misconception is that sexual killers, particularly the lust murderer, must be insane because the crime is so outrageous. Although a minority of sex killers (typified by the disorganized subset) are psychotic, in fact most are not, as the severe symptoms inherent with a true break from reality including delusions, hallucinations, disorganized thought, and bizarre behavior would typically render the perpetrator unable to carry out more than a single act without detection and apprehension.

Victim

Victims tend to be unsuspecting, naïve, weak (a child or elder), and/or in the wrong place at the wrong time. Purposeful sexual killers, especially serial sex killers, target a specific type victim (e.g., short, muscular build with medium-length brunette hair). This choice may be based upon fantasy or on the remembrance of a specific individual who may have "offended" the perpetrator. The sociopathic nature of the killer does not allow him to perceive his act of killing as wrong.

The site selection also is important. Typically, the killer will encounter the victim in an isolated area or take them to a remote/secluded location, including within a residence, to act out the fantasy. In the more serious cases, the killer may employ a death chamber to hold the helpless victim.

Rarely, a victim may fall into the Stockholm syndrome and begin to empathize with the perpetrator. In such cases, she may become an unwitting

compliant chronic victim. In other instances, the female may partner with the dominant male to acquire victims for his or their mutual sexual desires; this participant may be either a female or a submissive male partner.

Injuries/Assault

The violence tends to be of a close-contact nature, including strangulation, suffocation, or multiple hand-to-hand wounds. Asphyxial deaths and neck wounding tend to be favored modes of violence. The site of the injuries are important, specifically among those involving sexually significant areas, such as breasts, genitalia, neck, back, and buttocks. A related finding is the presence of overkill, or more injuring than is necessary to accomplish the killing. In older literature, such attacks were commonly attributed to a male homosexual partner. More recently, other categories of assailants have been recognized, including any intimate partner, intoxicated on stimulant drugs, and mentally ill (psychotic/schizophrenic).

Postmortem mutilation, such as mastectomy, vulvectomy, proctectomy, or emasculation of the penis, is intended to arouse the attacker. A common such wound is the incision of the abdomen with or without evisceration of various internal organs, including the internal genitalia. Excessive premortem wounding may represent the intent of the perpetrator to make the victim suffer during the assault. In such instances of torture, there may be isolated/combined bondage, bite marks (to sexually significant areas), repetitive wounds, and electrocution. Although rare, the killer's sexual fantasy may involve anthropophagy, or eating part(s) of the victim in a bizarre bonding-like ritual by which the killer feels more "spiritually connected" with the decedent.

Categories of Sexual Homicide

Four categories of purposeful sexual homicide are recognized, namely: organized, disorganized, mixed, and sadistic. In all instances, a sexual act is the basis for the eventual homicide. This act may be obvious, but the significance of the act, as well as the type of act itself, resides with the perpetrator. Although common, penile penetration is not a requisite function. Foreign body rectovaginal and/or oral insertion may be preferred. Often, there may be no direct evidence of ejaculation—the conventional sex act is not the killer's motive. Symbolism may be important with mutilation and/or display of the victim's body a prominent feature. The sex killer's thrill may come from a desire to shock responders and law enforcement with the brutality of the act.

The organized killer is typically intelligent and plans his actions carefully, taking pains to avoid detection and capture. He tends to be mobile and has transportation and will seek out a victim at a distance from his comfort zone. He is usually verbally adroit and will talk the victim (usually a stranger) into his control. His act is fantasy driven and thus ritual (including sadism) is a significant component of the act. The organized killer often takes souvenirs of the crime to continue the fantasy elements of the act.

The disorganized killer is the converse of the organized. Typically inadequate socially and of below-average intelligence, the perpetrator tends to act impulsively on an existing fantasy without significant planning of the sexual component. The disorganized offender will often depersonalize the victim by obscuring the face in some way. The assault is also often marked by mutilation of the body.

Not all patterns are so neatly distinguished. In many there is some overlap between in the level of organization. When the lines are blurred to the point where separation becomes futile, the killer is designated a mixed type.

Finally, the rarest type is the sadistic sexual killer. His motive is simply to control the victim and make the victim suffer. This killer enjoys the act of killing.

The amount of time the killer spends with the victim's body may suggest his comfort level and degree of personalization of the victim. The killer may also attempt to stage the scene in order to deceive investigators. Trophies may be taken from the victim as a fetish with which the killer remembers and fantasizes about the act. In the reliving of the prior attack, the serial killer idealizes the act and can improve techniques employed to attain his "perfect kill."

Shinto Beliefs and Traditions

"Born Shinto, Die Buddhist" aptly sums up the relationship between religion and life cycle in contemporary Japan. In a country where exclusive religious affiliation is the exception, not the rule, a generally accepted division of labor exists between Shinto shrines and Buddhist temples, with the former hosting such life-affirming events as the blessing of infants and small children and the latter handling funerals and other rituals concerning death. There are two main reasons for this split: (1) Buddhist priests in Japan, as elsewhere in Asia, came to dominate the performance of death rites because their faith provided highly articulated explanations of the afterlife and specific procedures to navigate it; and (2) Japanese have long believed that the native deities worshipped at Shinto shrines—beings called *kami,* who take the form of natural objects, human-like gods, or deified humans—abhor the pollution (*kegare*) generated by death. Concern about this pollution defines, in large part, the contemporary relationship between death and Shinto (meaning "the way of the kami"), so a discussion of its historical basis and ritual consequences follows.

Death Pollution and the Imperial Court

The idea that death is polluting extends back into ancient times. A Chinese record dating to the 3rd century notes that the Japanese made a practice of immersing themselves in water after funerals as an act of purification. Concern about the pollution generated by death and measures to combat it also figure prominently in indigenous creation myths, which were not officially compiled and written down by the imperial court until the 8th century, but which had likely circulated in one form or another for many generations.

The most important of these myths concerns Izanagi and Izanami, the male and female kami who together created the islands of Japan. In a stark demonstration of the slippage between mortals and gods characteristic of kami worship, Izanami dies after giving birth to the fire deity and is consigned to Yomi, a gloomy underworld comparable to Hades in Greek mythology. The anguished Izanagi pursues his wife in the futile hope that he can bring her back to the world of the living. Initially welcomed by Izanami on the condition that he not look upon her, Izanagi incurs his dead partner's wrath by lighting a fire and beholding her maggot-ridden, decomposing body. He flees in horror while the shamed Izanami and other denizens of Yomi give chase. Once he escapes into the open, Izanagi stops his pursuers by placing a large boulder in front of the entrance to Yomi, and his estranged wife responds with a curse, heralding the introduction of death into the world of the living. In the wake of his traumatic experience, Izanami declares, "I have been to a most unpleasant land, a horrible, unclean land. Therefore I shall purify myself." He accordingly performs ablutions in a river, giving birth to more kami in the process. Supreme among them is the sun goddess Amaterasu, progenitor of the imperial line.

Amaterasu's self-proclaimed descendants and the courtiers who surrounded them took for granted that all kami shared Izanami's disgust for death, and thus developed elaborate rules to shield the fastidious deities from it. Regulations established in the Heian period (794–1185 C.E.) required those in mourning, or even those who had simply come in contact with the dead, to refrain from serving the kami for at least a month. The court was particularly strict regarding the imperial shrine

at Ise, dedicated to Amaterasu. For most of Japanese history, the worship of deities specific to Japan intertwined with Buddhist teachings and practices—so much so that kami were commonly viewed as the local incarnations of Buddhas and were enshrined in ritual centers that liberally combined indigenous and imported elements. Yet their close involvement with death and its management was one of the main reasons Buddhist clerics were banned entirely from the precincts of the Ise shrine. In fact, anything associated with Buddhism, and by extension death, was barred from Ise, making it a remarkable exception to the prevailing rule of blending the worship of kami and Buddhas.

Death Pollution and Folk Practice

Ordinary Japanese shared in the court's concern to shield kami from death pollution, creating prophylactic traditions that continue to this day. The most explicit of these is the custom of placing a white cloth or piece of paper over the *kamidana,* a miniature household shrine commonly affixed to a wall inside the home, after someone in the family has died. Many Japanese will also refrain from visiting Shinto shrines for up to a year after the death of a close family member.

The desire to shield kami from death pollution has traditionally extended to humans as well. Contemporary Japanese, unlike their distant forbearers, may not immerse themselves in large bodies of water after going to a funeral, but many still toss salt on themselves before reentering their homes. Salt, like water, is considered to be a purifying substance, and a mourning family will make sure that small packets of it—usually provided by the undertaker—are made available to those attending a funeral.

Until relatively recently, Japanese took even stricter measures to deal with death pollution. In certain communities, for example, it was once common for those visiting a house in mourning to wear disposable sandals and sit on specially provided mats. They also refrained from eating anything cooked in the home, as the cooking fire was thought to be contaminated by death. The now largely abandoned custom of bathing and vigorously scrubbing the corpse was another measure related to concerns about death pollution, as was officially sanctioned discrimination against families engaged in occupations, such as burying humans and butchering animals, that brought them in contact with death. Outcaste status was legally abolished in 1872, but discrimination against former outcaste families (now called *burakumin*) persists in some areas of Japan to this day.

Concerns about death pollution have diminished greatly in recent times, but, as the continued provision of salt at funerals shows, they have not vanished entirely. Certain acts associated with death—and thus with misfortune, if not death pollution per se—continue to be taboo in everyday life. For example, Japanese know not to stand chopsticks upright in a bowl of rice unless they plan to offer it to the dead, and also not to pass an item from one set of chopsticks to another, since it is customary after a cremation for family members to lift the bones with large chopsticks, two people at a time, and place them in an urn.

When Shinto took shape as an organized religion in the 19th century (more on that in later text), it incorporated and systematized longstanding folk beliefs concerning pollution and purity. Today, no shrine is complete without its ritual washbasin where visitors pour water over their hands and/or rinse their mouths before approaching the resident kami. And in performing blessings, whether of babies or of new cars, Shinto priests wave a wand crowned with folded white paper in an act of purification called *harai*. Priests are also asked to perform harai at construction sites, which are usually sprinkled with purifying salt and cordoned off with ceremonial ropes. But while Shinto purification rites ward away danger, they do not directly confront death—this in spite of a vaguely defined notion that, after the dead pass out of living memory, they acquire the status of a (hopefully) benevolent ancestor (*sosen*), putting them on par with the kami.

As noted earlier, the ritualization of death falls instead to Buddhism, which has dominated Japanese funerals and memorial services for centuries. When Buddhist teachings took root in ancient Japan, they contributed to prevailing notions about the pollution generated by death and other blood-tainted events, such as menstruation and childbirth. Yet these same teachings, with their emphasis on universal compassion and salvation, also encouraged Buddhist clerics to develop the ritual means to mitigate the danger of death pollution in the present while saving the deceased from

a horrible fate in the future. Offering the hope of salvation, they propagated death practices that have changed in content and meaning over time, but continue to play a prominent role in Japanese funerals and memorial rites today.

Shinto Death Rites: Exceptions to a Buddhist Rule

There are, nonetheless, prominent exceptions to the truism that Shinto celebrates the auspicious occasions of life, while Buddhism handles the ritualization of death. A tiny percentage of Japanese—including, significantly, the imperial family—hold funerals and memorial rites that are explicitly Shinto. Also, it is a Shinto, not Buddhist, institution in Tokyo, the formerly state-supported Yasukuni shrine, that enshrines the heroic spirits (*eirei*) of millions of Japanese who lost their lives in military service to the emperor. The following section, divided into two halves by the Meiji Restoration of 1868, explains the political history that gave rise to Shinto death rites and Yasukuni.

The Politics of Exception: Pre-1868

The practice of revering the deceased as kami, although exceptional, has a long history. Buddhism provided the usual means to explain and manage the afterlife, but if a powerful and angry spirit (*onryô*) caused trouble, enshrining it as a kami was a way to mollify it. The most famous onryô-turned-kami is Sugawara no Michizane, a 9th-century courtier and renowned scholar who ran afoul of powerful figures at court and was therefore banished. After he died in exile, a series of disasters struck the capital. Fearing these to be the result of Sugawara's wrath, the court decided to build him a shrine, subsequently transforming him into the kami Tenjin. Today Tenjin is considered to be a beneficent kami of learning, and the many shrines now devoted to him are frequented by students praying for academic success.

Enshrining the dead as kami was reserved for special cases in medieval Japan, but it set an important example for those who, in the 18th and 19th centuries, embraced an increasingly popular school of thought known as nativism (*kokugaku*). Seeking to link the emperor, his subjects, and kami through purely Japanese forms of worship, nativists condemned Buddhism for supposedly hijacking the kami and corrupting indigenous practices, this in spite of the fact that kami worship had been integrated into a Buddhist frame of reference for well over a thousand years. Determined to expel the foreign, they understandably called for a return to putatively ancient, pre-Buddhist ways. Yet by explaining, revising, and systematizing various teachings and practices associated with kami worship, the backward-looking nativists of early modern Japan in effect invented Shinto as a self-aware "religion" with distinct rituals, institutions, and doctrines (whether concerning death or anything else).

As nativists advocated presumably ancient Shinto in place of "foreign" Buddhism, the ritualization of death presented serious difficulties. For one, most Japanese accepted as a matter of fact that kami recoiled from death and anything associated with it. Also, the ancient court texts central to nativist thought—written in Chinese characters imported, along with Buddhism, Confucianism, and Taoism, from the continent—yielded only fragmentary evidence of indigenous, pre-Buddhist death rites.

Ironically, the promoters of a presumably ancient and uniquely Japanese "way of the kami" dealt with this latter problem, in part, by drawing on Confucian (and therefore Chinese) protocol for managing death. This included inscribing a mortuary tablet with the name of the deceased (in contrast to the Japanese Buddhist custom of providing the dead with a posthumous ordination name), as well as specific procedures for handling the corpse. Nativists also borrowed methods developed by the Yoshida lineage of kami worship. Several centuries earlier, the Kyoto-based Yoshida lineage had already regularized the practice of enshrining the dead as kami, employing purification rituals specific to kami worship to transform dead patriarchs into guardian deities rather than put them on the path to Buddhist salvation.

Shrine priests involved in the nativist movement of the 18th and 19th centuries who sought alternatives to Buddhist death rites tried to affiliate with the Yoshida lineage to adopt its kami-producing death rituals. However, standing in their way was the policy of the Tokugawa shogunate (1600–1868), requiring every family to maintain registration with a Buddhist temple, a blanket rule designed to ensure that Japanese eschewed Christianity and

other teachings considered politically dangerous. Because the government forbade Japanese to sever ties with their family temples except in rare circumstances, the Buddhist clergy wielded considerable power over families—especially over their performance of death rituals. So while some priests in the mid- to late-Tokugawa period were successful in shedding their temple affiliations and adopting Yoshida-style funerals, many were stymied by a Buddhist establishment jealous of its prerogatives.

The Politics of Exception: Post-1868

Circumstances for nativists changed radically after the Meiji Restoration of 1868, a coup d'état led by disgruntled samurai who deposed Japan's last shogun in the name of the venerable but long disempowered imperial house. Numbering among the leaders of the new regime were prominent nativists, who quickly engineered an imperial decree ordering the "separation of kami and Buddhas" (*shinbutsu bunri*), a policy that inspired, if not officially authorized, a radical campaign to "destroy the Buddhas and annihilate Shâkyamuni" (the historical Buddha of northern India; *haibutsu kishaku*). The intensity of anti-Buddhist sentiments and actions varied according to region, but throughout the Japanese islands, Buddhist priests were defrocked, temple bells melted down, and worship centers violently stripped of Buddhist implements and practices. The outright persecution of Buddhism was short lived, but the religion never regained the official standing it enjoyed prior to the Restoration. With Buddhism disestablished, nativist officials elevated Shinto in its place, and they set about creating a system of shrine-based teachings and practices centered on the emperor. Their ultimate goal was to construct a widely accepted Shinto faith that would not merely complement Buddhism but displace it.

As part of this effort, they promoted Shinto funerals in place of Buddhist ones, and starting at the top, quickly orchestrated the imperial household's conversion from Buddhist to Shinto death rites. The harder job was convincing ordinary Japanese to abandon Buddhist death rites in favor of Shinto ones, as most were deeply committed to the Buddhist rituals that had linked one generation to the next for centuries. The government also worried about the administrative consequences of releasing Japanese from Buddhist oversight without providing a new form of supervision in its place.

This is why, in 1872, nativist officials publicized a standard format for Shinto funerals that combined Confucian death practices and admonitions concerning filial piety with principle features of kami worship, including ritual clapping, bowing, and offering of sacred *sakaki* tree branches. Desiring to make Shinto funerals widely available while monitoring their performance, officials also decided in 1872 to order all Shinto priests—now regulated by the government—to officiate the unfamiliar ceremonies. Yet in doing so, they still faced the problem that most Japanese believed coming in contact with death disqualified someone from approaching the kami anywhere from a month to a year. A cleric who honored this belief would find it impossible to participate in death rites on a regular basis and at the same time properly execute his duties as servant of the kami. The government dealt with this ritual problem by devising a blunt solution: it decreed that a simple act of purification (harai) would allow a priest to perform a funeral one day and resume his service to the kami on the next.

But declaring an answer on paper was one thing, winning its acceptance another. Despite the government's decree, for most Japanese, a Shinto funeral remained the ritual equivalent of mixing oil and water, a view shared, in fact, by many of the Shinto priests commanded to perform the new death rites. Priests were also divided over the character of the afterlife and the hierarchy of kami inhabiting it. Some nativists adhered to the not-very-attractive scenario depicted in the myth of Izanagi and Izanami: the dead reside in the gloomy underworld of Yomi, end of story. However, the majority imagined rosier circumstances for the dead—and subsequently engaged in bitter theological disputes about the precise nature of those circumstances and the otherworldly lines of authority that determined them.

These disputes, as well as popular resistance to the more radical elements of the nativist agenda, convinced national officials to withdraw state support for the Shinto funeral campaign in the late 1870s. In 1882, the Home Ministry went so far as to ban high-ranking priests at state-controlled

shrines from performing funerals. Clerics who wished to found independent sects and were free to officiate, but those in charge of Shinto rites at major shrines were cut off from the rough-and-tumble world of grassroots ministry. The prohibition was a key element of the Home Ministry's effort in the 1880s to create a formal distinction between private, sectarian Shinto on the one hand and public, state Shinto on the other. The latter, officials argued, was in fact not a religion but instead a "national teaching" that supposedly transcended the narrow interests and petty squabbles of religious sects, Shinto and otherwise.

The Home Ministry's move took any remaining steam out of the Shinto funeral movement—today very few families perform the anomalous death rites—but the state did not completely distance itself from the ritualization of death. Soon after the Restoration, the new regime founded a shrine in Tokyo to worship soldiers who had died in service to the emperor. Named Yasukuni, or "pacifying the nation," in 1879, the shrine apotheosized increasing numbers of the military dead as Japan battled to expand and defend its growing empire. Today, several million "heroic spirits" are enshrined at Yasukuni. These include Japanese executed as war criminals, so visits to the shrine by politicians regularly generate controversy both in Japan and the rest of East Asia, where bitter memories of Japanese occupation remain strong.

And yet, while the souls of millions of Japanese are collectively enshrined at Yasukuni, their bodily remains are dispersed among battlefields overseas or family graves throughout Japan. It is also worth remembering that the funerals held for these individuals were overwhelmingly Buddhist, as they were and continue to be for Japanese in general. So the ceremonies performed on behalf of the dead at Yasukuni may be prominent, but they remain Shinto exceptions to a Buddhist rule. An attachment to Buddhist traditions and a persisting desire to shield kami from defilement make Shinto a matter of life, not death, in the eyes of most Japanese.

Sin Eating

Sin eating is an English funerary custom of the 17th century, our knowledge of which rests heavily on the evidence of a single man, the antiquary John Aubrey (1626–1697). In his notes on folk beliefs and customs, *Remaines of Gentilisme and Judaisme,* he wrote:

> In the County of Hereford was an old Custome at funeralls to have poor people, who were to take upon them all the sinnes of the party deceased. One of them I remember lived in a cottage on Rosse high-way. He was a long, leane, lamentable poor raskel. The Manner was that when the Corps was brought out of the house and laid on

> the Biere, a Loaf of bread was brought pout and delivered to the Sinne-eater over the corps, as also a Mazer-bowl of maple full of beer, which he was to drink up, and sixpence in money, in consideration whereof he took upon himself ipso facto all the Sinnes of the Defunct, and freed him (or her) from walking after they were dead.

This custom, says Aubrey, had been kept up even in Puritan times in some places in Herefordshire and Brecon: He believed it had once been done throughout Wales, but in his own time was rare.

In 1714 to 1715, some years after Aubrey's death, another antiquary, John Bagford, wrote in a personal letter that he had read in a "Collection of Curious Observations" by Aubrey (since lost) that sin eating had also been practiced in Shropshire villages near the Welsh border "within the memories of our fathers." An old man would be given a small coin, a crust of bread, and a bowl of ale, after which "he pronounced . . . the ease and rest of the Soul departed, for which he would pawn his own Soul."

Finally, in 1852, a certain Matthew Moggridge claimed that sin eating had existed "within the past twenty years" at one place in Wales, and moreover that a sin-eater was shunned and detested by everyone because he carried all the sins of those for whom he had performed the ritual. How far he should be believed is uncertain.

Victorian folklorists hunted for further evidence. They easily discovered instances of bread and ale, or cakes and wine, or bread and cheese being consumed by mourners around the coffin before it was carried from the house, and/or distributed to the poor—but found nothing more about the human scapegoat, the sin-eater. Two scraps of hearsay evidence were reported from East Anglia by 20th-century folklorists. In 1945, L. F. Newman was told that sometimes in the 19th-century, bread and salt that had been laid on a corpse would be given to some unsuspecting beggar, who thus acquired its sins; fearing this trick, tramps still avoided houses where there had been a recent death. In 1958, Enid Porter reported that she had been told that an old woman who had died in 1906 had heard tell, when she was young, of a woman who had become a sin-eater, presumably in the late 18th or early 19th century. She would eat bread and salt laid on the shroud of the dead, and would be paid 30 pennies, whitewashed to look like silver.

Despite the late Victorian anthropological interpretation of E. S. Hartland, who argued that sin eating was a survival of primitive ritual cannibalism, it is best understood in the context of other funerary customs of the late medieval and Tudor periods. These had been based on Catholic doctrines and practices that were condemned by Protestants at the Reformation; what Aubrey describes, well over a hundred years later, appears to be a confused attempt by post-Reformation generations to go on carrying out Catholic traditions.

The chief element in a Catholic funeral is, of course, the Requiem Mass. Here the priest, and at least some of the mourners, takes Communion while praying that the sins of the dead person will be forgiven. Protestant theology forbids such prayer, which has no place in a funeral service. Yet vague memories of the Requiem surely inspired the custom of mourners eating and drinking beside the coffin, giving it symbolic force and spiritual value. In 1671, a French Catholic, Jorevin de Rochefort, mockingly described how at a funeral in Shrewsbury "there stood upon the coffin a large pot of wine, out of which everyone drank to the health of the deceased, hoping he might surmount the difficulties he had to encounter on his road to Paradise" (cited by Charlotte Burne). In Herefordshire, E. M. Leather heard how, even at the end of the 19th century, one of the guests at a funeral who declined a glass of port was explicitly told by an old farmer, "But you must drink, sir. It is like the Sacrament. It is to kill the sins of my sister."

Another common medieval custom at the funerals of wealthy people had been to distribute food and money to the poor, who in their gratitude would pray for the soul of the deceased. This was done by the coffin or at the graveside. It was based on a passage in the Book of Tobias (or Tobit), which forms part of Greek and Latin Bibles, though omitted from Protestant ones: "Alms deliver the soul from all sin, and from death, and will not suffer the soul to go into darkness. . . . Lay your bread and your wine on the grave of a just man" (Tobias 4:11, 18). To give alms to sin-eaters carried on this tradition, even though its roots in official religion and biblical authority were forgotten.

Social Class and Death

Tragic events often dramatize how individuals' social class determines where, when, and how they die. Class-based stratification systems—determined by one's location within the hierarchies of economic affluence, social prestige, and bureaucratic authority—are one of the most potent determinants of occupation, lifestyle, beliefs, and social opportunities in capitalist societies.

Two such examples of tragic events exemplify the connection of social class and death. Out of the approximately 1,400 passengers on board the *Titanic* in 1912, 535 survived that fateful April night in the cold waters of the north Atlantic. Survival rates were not an equal opportunity. Among first-class passengers, 36% perished, compared to 61% of second-class passengers and 73% of third-class passengers. The crew fared badly as well, with only 22% surviving.

Ninety-three years later, when Hurricane Katrina pounded and flooded New Orleans, the poor living beneath the waterline, in precincts below sea level, once again perished disproportionately. The evacuation plan was based on people driving out of New Orleans. However, 35% of black households did not have access to a car, compared to 15% of whites. Media images of unattended corpses lying in the streets conjured images of third world ghettos. Within weeks of the 9/11 attacks on the World Trade Center, Americans came to know the names, occupations, and final messages of the victims, many of whom were in upper-middle class professions. In the same time frame, Katrina's poorer victims remained nameless, faceless souls warehoused in morgues.

One of the greatest inequalities of life is how much of it one has. In other words, the rich not only have qualitatively better lives, but quantitatively more as well. In 2005, the income gap between America's haves and have-nots reached levels not seen since before the Great Depression, with the top 300,000 individuals earning more than the bottom 150 million combined. Concurrently, although the overall U.S. death rates have declined substantially in the past few decades, the gap between socioeconomic groups has widened. And it was large to begin with. In 1986, for every 1,000 white males age 25 to 64 with incomes of less than $9,000, there were 16 deaths, 6.7 times more than the 2.4 deaths occurring among their counterparts earning $25,000 or more. Among black males, the rates per 1,000 were 19.5 and 3.6 deaths, respectively, for the lower and higher income groups. These inequalities of ratios of mortality rates more than doubled since 1960.

Such death inequity is not unique to the United States nor to modern times. When Tolstoy's terminally ill high court judge Ivan Ilyich inquired how the peasants die, one inference was their greater familiarity with death. In fact, the very genesis of stratification ideas may have derived from observed differences in the death rates of different social groups. Early Egyptian priests undoubtedly had reinforced beliefs about their special station in life when observing those tending the flooded rice fields, workers crippled and short lived, owing to schistomiasis and other aquatic parasites infecting their bodies. In *Plagues and Peoples,* historian William McNeill hypothesized that the Indian caste system developed as Indian civilization encountered disease as they incorporated the "forest people," resulting in strict separation of groups and taboos against physical contact.

Class-based stratification systems emerged with early industrialization, producing its own set of lethal occupational hazards that disproportionately afflicted those on the lower social rungs. In London in 1830, the average age at death for the gentry

was estimated to be 44 years, dropping to 25 years for tradesmen, clerks, and their families, and only 22 for laborers and their families. A century and a half later, the death rate from amenable causes of New Zealand men from the lowest socioeconomic group was 3.5 times higher than men in the highest socioeconomic group. In 2005, a Scottish boy from the wealthiest Glasgow suburb has a life expectancy of 87.7 years, while one from the city's poorest areas can expect to die at 54. In the United States, male high school dropouts are roughly twice as likely to die of chronic (e.g., heart disease) and communicable diseases and more than three times as likely to die as a result of injury than those with 13 or more years of education.

Causes of Class Differences in Mortality

The causes of such class-based life-expectancy inequalities are life long and numerous. They include poor nutrition, unsanitary life situations, lethal occupations, and lack of medical insurance (the condition of nearly one in six Americans in 2005). Also implicated are differences in lifestyle. However, one study found that while lower-class individuals were more likely to smoke, be obese, consume excessive amounts of alcohol, and engage in less physical activity, these risky behaviors failed to fully explain why those with annual family incomes of less than $10,000 were three times more likely to die than those making $30,000 or more. Also involved were greater life stresses and levels of anger, and decreased self-esteem, senses of control, and social supports.

The inequalities of life and death begin at birth. Class inversely correlates with poor prenatal care and low birth weights, both of which increase infant mortality. A 1991 Centers for Disease Control and Prevention (CDC) study found a 4-pound infant is 4 times as likely to have birth defects as an 8-pound baby; low birth rate infants have a 25% chance of perishing before the age of 1 year. As inequality has increased in the United States, the percentage of newborns of low (less than 5.5 pounds) and very low (3 pounds, 4 ounces) birth weights increased from 1990 to 2005, reaching the highest percentages since the early 1970s. Uninsured children (representing one in nine of all American youth in 2005) are twice as likely to die of their injuries in American hospitals as insured children.

Class correlates with exposures to environmental hazards. Racial minorities and the poor are disproportionately exposed to air and water pollution, asbestos, lead, and hazardous wastes—producing a new dimension of inequality called "ecoracism." They live where others refuse, such as next to toxic factories. In the working-class district of Tlalnepantla, Mexico City, in 1984, 80,000 barrels of gas exploded at a liquefied petroleum gas facility, killing hundreds. Three weeks later, in a similar neighborhood of Bhopal, India, toxic gas leaked from an American-owned insecticide plant, killing thousands. These greater exposures of lower-class individuals to environmental hazards are also symbolic. In 1990, while 20% of all billboards in white Baltimore neighborhoods advertised alcohol and tobacco, in black neighborhoods the percentage was 76%.

The most lethal occupations in the United States—fishing, logging, mining (particularly uranium and coal), truck driving, and construction—are typically working-class jobs. Further contributing to class inequalities are exposures to violence, both sanctioned and unsanctioned. Victimization of unsanctioned violence, specifically homicide, is also greater for the poor and working class. Few class differences in casualty rates occurred during the Vietnam War (the last war fought by draftees); however, with the all-volunteer army, social class once again becomes inversely correlated with the likelihood of being a military casualty.

Class differences in mortality rates remain even when medical access is controlled. The first of the famous Whitehall studies, surveys of the mortality rates of British male civil servants age 20 to 64 between 1967 and 1977, all of whom had access to medical care and none impoverished, found those in the lowest of six grades (i.e., doorkeepers) had a mortality rate three times greater than those in the highest grade (i.e., administrators). When controlling for such cardiovascular risk factors as smoking, obesity, and high blood pressure, the difference in rates was still more than twofold. Studies of subsequent cohorts with focus given to different causes of death (e.g., cardiovascular diseases, diabetes, and cancer) reveal the greater stress of the lower classes to be a potent factor in explaining the difference.

Interestingly, the greater the economic inequality in a given area—whether it be a city, county,

state, or nation—the lower the life expectancy for all social classes. In a study of 282 metropolitan areas, those with high income inequality and low average incomes had 139.8 more deaths per 100,000 than areas with low income inequality and high average incomes. Further, for lower-class individuals, the higher the socioeconomic neighborhoods within which they live, the higher their death rates.

Interactions Among Class, Race, and Ethnicity

In October 2007, the chief of the Department of Justice's voting rights division caused a political firestorm when addressing the National Latino Congresso in Los Angeles. In claiming how Photo ID restrictions at the polling do affect the elderly and how that's a "shame," he added that minorities needn't worry because "minorities don't become elderly the way that white people do. They die first."

Exacerbating the class effects on American mortality rates is the racial factor, producing a double jeopardy. Native Americans age 15 to 24 commit suicide at 3 times the national rate and die in alcohol-related incidents at 17 times the national average. African Americans die earlier than their white counterparts, even when class measures are controlled for. In the United States in 1900, more than 6 in 10 (63%) white females and more than 3 in 10 (32%) nonwhite females could expect to survive to the age of 60. This nearly 2-to-1 ratio is found for males as well; 55% of white males and 28% of nonwhite males survived to age 60.

During the 1985 to 1989 period, life expectancy differences between black and white Americans increased on an annual basis. In fact, owing to the decade's AIDS and homicide epidemics, the life expectancy of black males actually decreased—the only group within developed nations not to experience an increase in life expectancy. In a 1996 study, University of Michigan researchers found that African American females living to age 15 in Harlem had a 65% chance of surviving to age 65, about the same as women in India. Meanwhile, Harlem's African American males had only a 37% chance of surviving to age 65, about the same as men in Angola or the Democratic Republic of Congo.

Given how growing inequalities of the life expectancies of social classes is strongly related to their inequalities of income (with differences being amplified among minorities), the possibility of death in triggering class conflict is always a possibility. Mortality rates have become a form of political box scores, gauging the adequacy of nations' economic development, welfare systems, and institutionalized social justice. In 2007, the United States ranked next to the bottom of 33 industrialized nations in its newborn mortality rate and 42nd of all countries in its citizens' life expectancy (down from 11th position 2 decades earlier).

Class Differences in Mortuary Practices

The inequalities of attention giving in life do not end with death. Cemeteries, for instance, reaffirm the social order of the living, with the most prominent locations and memorials reserved for the elite. Minorities and the poor will have their own final resting places either beneath numbered plaques in some potter's field for the indigent or segregated within a community's common burial site. Obituaries also reaffirm the social registry. The higher the individual's social class, the more likely they will receive an obituary.

England's 1832 Anatomy Act, in an attempt to counter a plague of body snatchings, permitted the dissection of "unclaimed bodies," which invariably would be the poor from workhouses and public hospitals. That poverty would be the grounds for dissection represented the final indignity, a stigma dating back to Henry VIII's edict limiting dissection to hanged murderers and an affront to a Christian population believing that the body must remain intact in order to be reunited with the soul during the Last Judgment.

When those at the lower socioeconomic rungs have financed their funerals, they often pay proportionately more. During Victorian times, the lower classes would bankrupt themselves aping the ceremonies of the elite, perhaps trying to give to family members the dignity never received in life. This period of early industrialization and urbanization was an era of increasing mortality rates, and when wealth, respectability, and salvation were linked, all classes desired a "good" funeral. In the late 20th and early 21st centuries, affluent

Americans were more likely to choose less expensive funerary options, particularly cremation, than those of the working class.

Social Functions of Death, Cross-Cultural Perspectives

Death occurs in all societies, yet it evokes an incredible variety of responses. At the moment of death, survivors in some societies remain rather calm, others cry, and still others mutilate their bodies. Members of some societies officially mourn for months, while others complete the ritual within hours. In many societies, families are involved in preparing the corpse for the funeral ritual; in others, families engage professional funeral directors to handle the job.

The variety of responses to death are noted by Richard Huntington and Peter Metcalf in *Celebrations of Death: The Anthropology of Mortuary Ritual.* Corpses are burned or buried, with or without animal or human sacrifice; they are preserved by smoking, embalming, or pickling; they are eaten—raw, cooked, or rotten; they are ritually exposed as dead or decaying flesh or simply abandoned; or they are dismembered and treated in a variety of these ways. Funerals are times for avoiding people or holding parties, for weeping or laughing, or for fighting or participating in sexual orgies.

Whereas death rituals in the United States are generally subdued and rather gloomy affairs, some societies engage in rather spirited activities. The Bara of Madagascar, for example, engage in "drunken revelry" at a funeral—rum is consumed, sexual activities occur, dancing takes place, and contests involving cattle occur. Among the Cubeo of South America, simulated and actual ritual coitus is part of the mourning ritual. The dances, ritual, dramatic performances, and sexual license have the purpose of transforming grief and anger over a death into joy.

In most non-Western societies, death is not seen as one event, but rather as a process whereby the deceased person is slowly transferred from the land of the living to the land of the dead. The process is illustrated by rituals marking biological death, followed by rituals of mourning, and then by rituals of social death. The deceased person is often viewed as a soul in limbo during rituals of mourning, though he or she is still a partial member of the society.

Understanding Death Rituals

Ritual, defined as a symbolic affirmation of values that are culturally standardized through the expression of utterances and action, is an effective means of reinforcing these important sentiments. Ritual makes death less socially disruptive and less difficult for individuals to bear. Rituals differ from other behaviors in that they are formal, that is,

stylized and repetitive in that these are performed in special places, occur at set times, and include liturgical orders.

Death Rituals as a Rite of Passage

When the social positions people hold in society change, identities change as well. Such transitions in identity require significant transitions in life as well, including the ability to adjust and adapt to these transitions. Human beings construct rituals as one means of acknowledging and adapting to change. Consider the following transitions: a child becomes an adult, a single person commits to another in marriage, a married couple becomes parents, a worker retires, and a person dies. In most societies, each of these transitions is marked by collective actions (or social rituals) that acknowledge a change in identity.

Death is a transition, the last in a series of transitions, or rites of passage. In many cultures and religions, being dead is another status change, replete with a new role and obligations. Often the dead are expected to give advice, cure illness, reward good deeds, and ensure a good harvest. In Ireland, the dead are called upon to cure the afflicted and to comfort the lonely. Thus, in Ireland, people never say farewell at a funeral because they fully expect to be in contact with their friends and loved ones again.

The moment of death is related not only to the process of afterlife, but also to the process of living, aging, and producing progeny. Death relates to life—to the recent life of the deceased and to the lives that he or she has procreated and now leaves behind. There is an eternity that divides the quick from the dead. Life continues generation after generation, and in many societies, it is this continuity that is focused upon and enhanced during the rituals surrounding a death.

Structural-Functional Explanations

The structural-functional perspective views funeral rituals as an equilibrium-producing process. Specific functions of rituals include validating and reinforcing values, providing reassurance and feelings of security in the face of psychological disturbances, reinforcing group ties, aiding status change by acquainting people with their new roles, relieving psychological tensions, and reestablishing patterns of interaction disturbed by crisis.

Similarly, burial rite functions can provide meaning and sanction to the separation of the dead person from the living. Moreover, burial rites help effect the transition of the soul to an otherworldly realm. These rituals also assist in the incorporation of the spirit into its new existence. Finally, death rituals are emphasized to re-create social solidarity and reaffirm social structure. Death disrupts social networks and relationships, and the rituals help restore order.

Reaffirming social structure is often accomplished through the family reunion that occurs as an unintended consequence, or a latent function, of the funeral ritual. The intended consequence, or manifest function, of a funeral is to pay respect to the deceased and to support the survivors. The latent function is to bring family and community together.

Burial ground serves as a symbolic representation of the social order. Among the Merina of central Madagascar, for example, after death one returns "home" to the tomb, representing a regrouping of the dead—a central symbol of the culture and an underlying joy of the second funeral. By the entry of the new corpses into the collective mausoleum, the tomb and the reunited dead within it represent the enduring descent group and the source of blessings and fertility of the future.

In older American cemeteries, family solidarity was preserved in the family plot, where many members of a single family were buried together in a space delineated by fences, headstones, and footstones. Shared tombstones for married couples often declared this family unity and solidarity with the epitaph "Together Forever."

Customs at Death

Most cultures encourage families and friends to become involved in preparing the corpse for its final disposition. There are two death-related cultural perspectives. First, different practices exist that are unique to the culture in which these occur. An alternative viewpoint is that there are common human needs (e.g., to dispose of the body), and each society creates practices, rites, meanings, and rituals that are functional equivalents to those found in other societies.

Rituals Performed Prior to Death

Having a cultural framework prescribing proper behavior at the time of death provides an established order and perhaps gives comfort to the bereaved. These rituals provide the survivors with something to do during the dying process and immediately thereafter, thus facilitating the coping abilities of the bereaved.

It is important in many societies, including the United States, that one is with the dying person at the time of death. A visit before death allows one to say goodbye. Among the Dunsun of northern Borneo, relatives are encouraged to come and witness the death. The dying person is propped up and held from behind. When the body grows cold, the social fact of death is recognized by announcing, "He exists no more" or "Someone has gone far away."

The Ik of Uganda place the dying person in the fetal position because death represents a "celestial rebirth." The Magars of Nepal purify a dying person by providing water that has been touched with gold. The Maori of New Zealand also have a ceremony intended to send the spirit of the dying person away while the person is still alive and conscious of what is happening. After the spirit is gone, the individual may not be biologically dead, but, in a Maori sense, "is dead." Ceremonies then commence and a space is set aside in the meetinghouse for the corpse to lie in an open coffin.

Final Disposition

Rituals and rites related to final disposition serve the functions of maintaining positive relationships with ancestral spirits, reaffirming social solidarity, and restoring group structures broken by death. In many cultures and religions, individuals are considered to be composed of several elements, each of which has a different fate after death. Thus, the actual destruction of the corpse, whether through cremation, burial, or decomposition, is thought to separate the elements—the various bodies and souls. There are two primary forms of final disposition, earth burial and cremation. The dominant religions that practice earth burial are Judaism, Christianity, and Islam, while Buddhism and Hinduism practice cremation. However, in all forms of final disposition, ceremonies declare that the body no longer has any value, but the soul lives on.

Native American burial practices, for example, provide evidence that tribal groups do not abandon their dead; rather, they provide the dead with ceremony in the disposal. Indeed, ceremony and the manner of disposition of the dead go hand in hand with death in different cultures. These disposition rites not only reaffirm group structure, but also enhance social cohesiveness.

In sum, the act of dying has an influence on others because it is a shared experience. This death-related sharing is composed of symbolically meaningful rituals. Because death meanings are socially constructed patterns of behavior, the meanings attributed to dying and death will be determined within the social setting in which they occur. Because death generally disrupts established relationships, cultural scripts aid in providing socially acceptable behavior for the bereaved. Such scripts are essential because these provide social continuity. Burial rituals are important in assuring social cohesion at the time of family dissolution through death.

Family involvement plays an important role in most societies as individuals prepare for death, as they prepare the corpse for final disposition, and as burial rituals that follow are performed. Therefore, whether death rituals involve killing a chicken, scraping the meat from the bones of the corpse, crying quietly, wailing loudly, mutilating one's own body, or burning or burying the corpse, all bereavement behavior has three interconnected characteristics—it is shared, symboled, and situated.

Soul

The various conceptions of the soul include but are not restricted to (a) a first principle or fundamental source of life found in a living thing, (b) a spiritual substance responsible for a thing's being alive and perhaps capable of existing apart from the body after death, and (c) the seat of the psychological operations of a being capable of conscious existence. A given explanation of the soul may be in response to one or more of these conceptions. For example, some have conceived of the soul as a spiritual substance that fits all three of these categories, whereas others have spoken of the soul as a material entity that fits only the first and, perhaps, third categories. In addition to having three notions of soul, further confusion arises because, while some analysts have treated the soul as a physical part of the body, contemporary materialists who believe that something physical exists and fits the first and third categories refrain from speaking of a soul.

This discussion is focused on the conception of soul as a first principle or source of life found in a living thing. A test for what fills the role of the first principle is to inquire as to what is no longer present at the time when what had been a living body ceases to be alive. Three approaches are common.

1. The soul may be taken to be a spatially extended physical object. There has been a common belief in ghosts as spatially extended ethereal beings that depart from the body at death. Alternatively, ancient Greek atomists, such as Democritus, held that the soul is made up of small spherical atoms, and when these depart, bodily death occurs. Plato spoke of a worry that some people had that the soul of one who dies on a windy night might be scattered and dispersed, precluding the possibility of its continued existence after death. If one conceives of the soul as the seat of psychological operations, then one might locate the soul in a part of the body. In the past, the heart was sometimes treated as the seat of emotions; today analysts are inclined to treat the brain as the seat of the emotions, consciousness, and intellect.

2. The soul is held to be a nonphysical spiritual substance that gives life to a living organism. This doctrine, "substance dualism" or "Cartesian dualism," is most closely associated with the philosophers Plato and Descartes. Descartes characterizes the nonphysical nature of the soul in terms of it as being a thinking thing that is not spatially extended—for Descartes, thinking involves any conscious process of which there is immediate awareness. Descartes's narrow conception identified the soul with the mind and held that it is the principle of conscious life. Nonhuman life, Descartes believed, can be fully accounted for mechanistically without appeal to the soul; we only need the soul/mind to explain the existence of a thinking being. It was a notorious feature of Descartes's philosophy that he thought nonhuman animals are altogether lacking in consciousness. It has also been common for substance dualists to hold that a nonhuman animal can possess a nonmaterial soul. Those, not in the Buddhist tradition, who accept the view that reincarnation occurs through a transmigration of the soul appear to be substance dualists.

3. A third approach has its roots in Aristotle's account of the soul. Aristotle held that physical things are a composite of matter and form. A thing is what it is in virtue of its form. Thus, due to a change in form, the same matter may at one time be grape juice, at another time be wine, and yet at a third time be vinegar. Of course, a thing need not retain the same matter to remain in existence; a living thing undergoing metabolism will exchange matter with its environment while remaining the same individual. What makes a living thing alive is that it has a substantial form in virtue of which it is a living thing of a given kind.

Aristotle takes the substantial form of a living thing to be its soul. Thus, for Aristotle, all living things have a soul. This does not entail that all living things have some form of consciousness, but they must have some vital functions to be alive. In virtue of its soul (or form), different grades of living things have different vital capacities. A plant has capacities to grow, take in nourishment, and reproduce in virtue of having a formal organization as a plant. An animal has the previous mentioned capacities plus the capacity to move about and have sensation in virtue of having an animal soul. A human animal also has rational capacities by virtue of its human soul.

Immortality and Personal Identity

Assuming that continued existence of a self or an individual living being requires the continued existence of its soul, there is a close connection between theories of the soul and the question of whether survival of death, or even immortality, is possible. If the soul is not distinct from the body, then it is hard to see how there could be survival of bodily death without a resuscitation or resurrection of the body. Similar considerations apply if the soul is a part of the body: it is easy to see how there could be survival of the death of the soul-part by a resuscitation or resurrection of the soul-part. Once there has been dissolution of the body, it is difficult to see what could count as a resurrection of the same living being. This problem is a special case of what philosophers call the problem of personal identity over time.

Several solutions have been advanced. One proposal holds that the resurrected body will have the same matter that it had when it was previously alive; alternatively, the resurrected body must have the same matter in the same arrangement that it previously had. But a living body's having the same matter and structure as a previously existing living body once had does not guarantee that the same living being is present in both. Imagine that the atoms that made up your body when you were 1 month old—none of which may currently be a part of your body—were reassembled into a configuration they had when you were 1 month old. They would not compose a person who is the same person that once had that body; after all, you are the person who had that body and the person with the recomposed body would not be you. Furthermore, among those who believe in a resurrection, it is commonly held that the resurrected body will not be like the body was when it died; it will not be an identical arrangement of identical atoms. Finally, atoms that constitute the body of one human at its death may be present in other humans when they die. But a belief in a simultaneous resurrection of all humans raises the question of who would get the shared atoms.

Another attempt to solve the problem of identity over time holds that there will be a psychological continuity between the person who dies and the person who is resurrected, and it is this continuity that constitutes personal identity over time. The psychological continuity is typically spelled out in terms of shared memory and similarity of psychological dispositions. A question has been raised whether psychological continuity could be sufficient to constitute the continued existence of the same person over time: it is argued that in theory it is possible for there to be psychological continuity between a person P_1 at one time and distinct people P_2 and P_3 at a later time. Because P_2 and P_3 are distinct from each other and each would have as much a right as the other to be identified with P_1, it follows that neither is the same person as P_1. Thus, the argument concludes, psychological continuity by itself is not sufficient for personal identity.

In the view that the soul is an immaterial spiritual substance, a straightforward solution to the problem of personal identity over time is to hold that continued existence of the soul is sufficient for the continued existence of the person. Because the soul is nonmaterial, the dissolution of the body does not obviously prevent the continued existence of the soul. This view leaves open the possibility of survival of death, with or without a resurrection, and any difficulties previously raised concerning the possibility of a resurrection of the body are mitigated on this account: as long as the soul of a person who died previously is presently associated with the newly formed body, the person with the new body will be the person who died.

Objections raised against Cartesian or substance dualism hold that it is impossible to account for how a nonmaterial soul or mind interacts with the body. It is difficult to see how a naturalistic account could be given of the emergence of an immaterial soul during the evolutionary process. Given that humans lose consciousness when the

living brain is sufficiently disturbed, it may seem that the soul does not have a capacity for consciousness that is independent of the body.

Finally, Aristotle held that if the capacities a being has in virtue of having a soul can only be exercised through bodily parts, then its soul cannot exist apart from the body. He believed that the capacities for reproduction, growth, nourishment, sensitivity, and local motion can have no existence apart from the body. But, he raised the question whether humans have an intellectual capacity that does not depend on a bodily part for its operation and, if so, whether the human soul could have some sort of intellectual existence apart from the body. An affirmative answer was extensively developed in medieval philosophy by Thomas Aquinas and others. It held that the soul can have at least a truncated existence apart from the body in which the intellect and will operate. Aquinas held that only in a bodily resurrection will the human be restored to a fully human life.

Spiritualist Movement

The spiritualist movement, centered in the English-speaking parts of North America and in the United Kingdom, is a loosely structured new religious movement (NRM) that emphasizes the immortality of individual spirits, contact with the spirit world through spirit mediums, and spiritual healing. Like spiritualism in the generic sense, found in various forms throughout the world, it denies the finality of death, but it also has many functions depending upon particular social conditions.

Although spirit mediumship is the role of the "spirit medium," and spiritual healing is the role of the "shaman," these two roles overlap in many societies. Both mediums and shamans contact the spirit world, the former for information, and the latter to harness the healing power of spirits.

Mediumistic and Healing Procedures

It is common for both spirit mediums and healers (shamans) to work in an altered state of consciousness, brought on by meditation and/or by prayer. In spiritualist churches today, this altered state is seldom deeper than a light trance, and it rarely involves spirit possession (a spirit taking over the body of the medium or healer). Nevertheless, mediums often say that they have a team of one or more spirit guides (sometimes called "controls") to help bring in messages from other spirits. Also, healers may attribute their healing power to "spirit," which could be anything from a general god-force to particular spirits working through the healer.

Spirit mediums report acquiring information from the spirit world in a variety of ways or "modalities." In one study of 98 American mediums, 70% reported being clairvoyant ("clear-seeing," that is, getting visual images), 61% said they were clairaudient ("clear-hearing," that is, getting voices or other sounds), and 40% thought they were clairsentient or kinesthetic ("clear-feeling" or experiencing body sensations). All of these modalities may be experienced either as realistic sensory inputs or as imagined or dream-like impressions.

Shamans use a great variety of healing procedures in world societies, but spiritualists in particular are trained to do "church healings." These typically consist of brief (5–10 minute) sessions in

which people from the congregation come up to sit on individual benches while the healers place their hands near the sitters' bodies, covering most of the body but with limited touching.

Functions of Mediumship and Healing

Anthropological studies have found a number of functions served by spirit mediumship. In traditional Chinese society, it has been used to discover what the ancestors need in the spirit world. Living relatives then burn "hell banknotes" (imitation paper money made specially for this purpose), or small-scale effigies of cars and houses, or plastic imitations of jewelry for their ancestors, expecting health and wealth from their ancestors in return.

Spirit mediumship has sometimes been used for political purposes, such as in East Africa, particularly Zimbabwe, where the highest status political leaders claimed the aid of the most powerful spirits. The ghost dance movement among Plains Indians (1885–1890) relied upon returning spirit ancestors to protect them against the U.S. military. In ancient Greece, the Oracle at Delphi was consulted for many reasons, including for spiritual advice in political and military affairs.

In the spiritualist movement, however, spirit mediumship has tended to have more of an individual or limited family and friend focus, and less of a focus on the clan or wider society. Spiritualist churches promote the idea that their main purpose is to "prove the continuity of life," or in other words, to convince people that bodily death is not the end of the soul's existence. This may mean alleviating anxiety among individuals about their own eventual deaths, and it may mean consoling people who have lost relatives and friends. Throughout the history of the spiritualist movement there have been revivals of interest in spiritualism during wartime, especially during the Civil War and World War I. Recent books by spirit mediums often emphasize this theme of grief management.

In most traditional non-Western societies this emphasis would seem strange. Chinese, for example, even in modern Hong Kong, have generally taken the spirit world for granted. It may have been feared, but seldom doubted. Westerners who come to have reuniting conversations with their loved ones through Chinese spirit mediums are considered odd. They should be there for practical reasons, finding out what to do for their ancestors, not to manage their personal grief.

Western spiritualist mediums also have norms against forecasting the death of people's relatives and friends. For example, it is acceptable to say, "You really ought to visit your grandmother," but few mediums would say that she is about to die. In fact there is a general taboo against passing on bad news of any kind.

Another function of mediumship stated by spiritualist mediums is that it should "help people." By this they mean that mediumship is a holistic healer, supporting an individual's spiritual, mental, and bodily health. The same claim is made for hands-on church healings.

Messages from the spirit world may relieve anxiety about death and the dead, but they may also contain particular advice about health. In Lily Dale, New York, the largest spiritualist camp, founded in 1878, mediums used to (as late as 1929 at least) give specific medical advice from the spirit world, but this is strictly discouraged today to avoid accusations of practicing medicine without a license. General tips about healthy lifestyles and seeing a doctor, however, are not uncommon in public readings at spirit message services.

Although spiritualist churches discourage or deemphasize it, there is yet another function of spirit mediumship, especially in private readings: fortune telling. If the ideology of spirit mediums emphasizes "proving the continuity of life," the main reason most clients come for private readings is to find out about such things as money, jobs, love life, and personal health. Nevertheless, some sitters (clients) do hope for contact with a particular lost loved one, sometimes expecting, nonetheless, some practical advice from the loved one.

History of the Spiritualist Movement in the United States

As is the case with other NRMs, the origins and organization of the spiritualist movement are complex and diffuse. American spiritualism sprouted from what has been called "the Burned-Over District" in western New York in the early 19th century after the completion of the Erie Canal in 1825. This rapidly developing area allowed for the spread of NRMs like Mormonism and Millerism (Seventh-Day Adventists), and of other movements

like feminism and the abolition of slavery, relatively unchecked by the more established social control systems (including churches) found "back east."

Spiritualist churches now consider their movement to have begun in this Burned-Over District, in Hydesville, New York, near Rochester in 1848. Two sisters, Margaret Fox, age 14, and Kate Fox, age 11, allegedly heard rapping noises in the family cottage. These sounds were interpreted as messages from the spirit world. The family then developed a code, which they claimed yielded a statement from the spirit of a peddler about how he had been murdered in the cottage and buried in the basement.

From this event, Quakers, Universalists, and Swedenborgians spread both the reputation of the Fox sisters and the practices of spirit rapping and table tipping (sitting around a table with one's hands on top, calling on spirits to make it rise or move about). Within several years, these phenomena had spread, especially throughout the United States and England. Margaret Fox confessed to fraud in 1888 but retracted her statement in 1889.

Alongside these spiritual phenomena and practices, a spiritual belief system also developed largely from the writings of Andrew Jackson Davis, born 1826 in Orange County, New York. Davis had a vision in 1844 of the ancient Greek physician Galen and of Emanuel Swedenborg, an 18th-century Swedish scientist and mystical philosopher. After his experience with Galen and Swedenborg, Davis began to perform intuitive diagnoses on patients and to prescribe alternative medical therapies. In 1845, he started lecturing in trance and writing books seemingly beyond his less than one year of formal education.

George Bush, a professor at New York University and the foremost expert on Swedenborg, examined Davis and his ability to dictate in Hebrew, Arabic, and Sanskrit, languages he was apparently unfamiliar with. Bush thought that Davis might be channeling (receiving spirit communications) from Swedenborg. Others thought that Davis might be plagiarizing the works of Swedenborg. Davis's books *The Univercoelum* and *Harmonia,* written between 1848 and 1850, just as the Fox sisters craze was spreading, became prominent in the spiritualist movement, helping to establish beliefs about natural law and the world of spirits.

Partly because spiritualism spread rapidly as a craze in the mid-19th century, and partly because spiritualists tended to resist organizing formally into the kind of church structure they opposed in mainstream religion, we know little about many details of the movement and about how serious it was. The claim is sometimes made that by the Civil War in the 1860s, nearly every American family had at least one spiritualist in it. However, many such people may have limited their involvement to table tipping or to séances (circles of people who sat around a table holding hands as a spirit medium tried to bring in spirits). Although some people sat faithfully in such circles an evening a week, for many it may have been no more serious than playing a board game.

More importantly, the spiritualist movement was associated with other radical movements because many early spiritualists were fallen-away Quakers (who thought that Quakers were becoming too organized), liberal Universalists, and a variety of "free-thinkers." Such related movements include the abolition of slavery, temperance and health reform, and women's rights. Spiritualists tended to be all-purpose radicals, too radical, for example, for most feminists. When Susan B. Anthony spoke several times in the 1890s in Lily Dale, the spiritualist camp, she encountered criticism from more moderate feminists.

Although it is debated just how formally organized the spiritualist movement was before the Civil War, it seems clear that there was more emphasis on creating a national church structure in the 1860s and 1870s. In many cultures, women have been able to gain spiritual power by taking the role of spirit medium, and the spiritualist movement provided the same opportunity compared to established churches that had a heavily male-dominated hierarchy. Once spiritualism became more organized, however, women tended to lose some status in the national groups.

Estimates of the numbers of spiritualists at different times in the United States are impossible to verify due to the participation of a high percentage who were never enrolled in churches, the large number of small coalitions and independent churches, and the fact that the U.S. Bureau of the Census is prohibited from collecting data on religion. There may have been millions of spiritualists in the late 19th century (a few percent of the population), probably a significant decline by the 20th century, and under a million at any one time

since 1926 (a fraction of 1%). However, in a sense, the legacy of the spiritualist movement lives on as one of the roots of the new age movement today, and impacts the current audience for spirit mediums on television, in books, at psychic fairs, and at spiritualist camps like Lily Dale. Throughout the history of the movement, many participants, even leaders, have been members of other churches.

Perspectives on the Spiritualist Movement

Although confronting issues of death is a cultural universal, and religions in all societies question the meaning of death, the spiritualist movement in Western society is in an especially problematic position. It is problematic for both scientific and religious reasons in this cultural context. Each of the next four subsections examines the spiritualist movement's orientation to death and to contact with the spirit world from a different perspective.

Spiritual

Spiritualists claim not only that the life of the spirit lives on past the death of the body, but also that it is possible to contact individual spirits after "so-called death." Most organized religions in the United States and in Great Britain either ignore this possibility or consider it impossible or potentially dangerous to seek out spirits this side of heaven (not to mention hell).

Even spiritual/religious traditions closer to spiritualism have been wary of the spiritualist approach. As previously noted, Andrew Jackson Davis borrowed ideas from Swedenborg, but Swedenborg considered spirits potentially unreliable sources of information. Spiritualists also assimilated concepts from Transcendentalists like Thoreau and Emerson, who disapproved of spirit mediumship. Emerson went so far as to call spiritualism "the rat hole of revelation." Later the Theosophical Society, an outgrowth of spiritualism founded by Madame Blavatsky and Henry Steel Olcott, ridiculed spiritualism for contacting lower-level spirits.

All of the criticisms of spiritualist mediumship found in these other traditions resonate with concerns that present-day spiritualist mediums worry about themselves. Some mediums worry about getting spirit messages from bad energies, envision "a white light of protection" around themselves, and pray for "the highest and best" spirits to come through. It is often said that "just because a person goes to the spirit world, that doesn't mean they get any smarter." Some mediums also encourage people to get in touch with higher spirit guides and teachers in order to become more spiritually evolved.

Having been raised in the same skeptical society as other Americans and British, where science has greater legitimacy than mysticism and spirit contact, spiritualist mediums also doubt their own work on scientific grounds. Most mediums look for confirmations, evidence that their spirit messages are valid, and continue to be pleasantly amazed when they think that good evidence has been established. Many prominent mediums, like Davis himself, were skeptics earlier in their lives.

Spiritualist churches state that spiritualism is a science, a philosophy, and a religion. They also emphasize that there are no religious dogmas, even though they do have a statement of principles that allows for individuals to come to their own understanding of the divine through their own experience. Spirit mediumship itself, they say, is a scientific procedure in that it provides evidence for the continuity of life.

Parapsychological

Although the legitimacy of spiritualist claims to be scientific declined by the end of the 19th century due to the professionalization of mainstream science, various scholars (some of them spiritualists themselves) have examined and tested spirit mediums since the mid-19th century. In 1882, the Society for Psychical Research was founded in London, members of which included eight fellows of the Royal Society. A similar organization began in the United States in 1884. Mixed results included the uncovering of fraudulent mediums but also many cases that some researchers considered authentic or unexplained.

Increasingly parapsychologists (students of allegedly paranormal aspects of the mind, including extrasensory perception, or ESP, and mental influence on objects, or psychokinesis, PK) have worked more in laboratory settings, as did J. B. Rhine beginning in the 1930s at Duke University. Studies of spirit mediums in their natural setting have declined. There is a tendency for

parapsychologists to be wary of the "survival hypothesis," the attribution of seemingly accurate statements by spirit mediums to contact with surviving spirits and to suggest instead that any information in the universe might be known by "super-ESP" (ESP with no space or time limits). Nevertheless, laboratory experiments and other scientific studies of spirit mediums continue today.

Scientific Skeptical/Debunking

There is no absolute separation between parapsychological research and scientific debunking, because both can operate from a perspective of scientific skepticism. However, the Committee for Skeptical Inquiry (CSI), formerly the Committee for Scientific Investigation of Claims of the Paranormal, takes the position that there is no credible evidence for spirit mediumship or spiritual healing.

CSI often attempts to demonstrate fraudulent paranormal feats by showing how they can be replicated by trick magicians. Spirit mediums, they say, often use "fishing" questions in their readings until they say something that extracts information from the sitter either verbally or through body language cues. Cooperative sitters may also interpret the medium's statements to make them fit.

Social/Behavioral Scientific

Most of this entry has been written from a social scientific perspective, pointing out the functions of spirit mediumship in various societies, for example. Spirit mediums or "channels" have often provided the ideology for religious movements by claiming to be sources of revelation. The spiritualist movement in particular has focused squarely on the mystery of death and provided one coping mechanism for dealing with death. Although mediumship poses a problem in terms of being accepted by mainstream natural science, social scientists can study its social functions, and psychologists can explore its psychological and neuroscientific aspects.

SPIRITUALITY

Since the early 1980s, the topic of spirituality, considered by some analysts to be a postmodern offspring of religion, has gained ascendancy among social scientists representing academic disciplines such as sociology, psychology, and gerontology, and the counseling, medical, and nursing professions. This interest has been spawned by rapid changes in societal values, disillusionment with traditional religious institutions in meeting individual needs, a drop in public confidence in religion and religious leadership, and a new cohort of baby boomers who have been described as a generation of spiritual seekers. While religion has always served an individual and an institutional function, the institutional component has come to

be seen as a fixed system of ideological beliefs and commitments that have failed to address the personal aspects of the human experience. Spirituality, on the other hand, is commonly regarded as an individual phenomenon, linked to concepts of transcendence, coherence, and purpose in life. In the following sections, social, theoretical, and methodological issues are addressed.

In North America in particular, a polarization of religiousness and spirituality has occurred, with the former often described as public, institutional, formal, authoritarian, and inhibiting expression and the latter as private, individual, subjective, inward, and freeing expression. While acknowledging the importance of religion and religiousness, the focus herein is on the construct of spirituality, the definitional problems and conceptual controversies, the challenges related to the measurement of spirituality, and the link between spirituality, health, and death attitudes.

Definitional Problems and Conceptual Controversies

The difficulty in the definition of spirituality emerges from the English language itself because of a lack of distinctiveness between the concepts "religiosity" and "spirituality." This can easily be compared to the German language, in which the word *geistig* describes the "human spirit" or spirituality, while the word *geistlich* describes "the sacred or the divine" as embodied in the concept of religiosity. The inability to distinguish between terms has contributed to the confusion, inconsistencies, and a diverse set of definitions of spirituality and religiosity. This is true not only in the lay community, but within the scientific community as well.

Historically, the terms *religiousness* and *spirituality* were used interchangeably with no real distinction made between them. *Religiousness* was the preferred term, although definitions were varied and diverse. The most commonly cited definition defined religiousness as adherence to a set of ideological beliefs, rituals, symbols, and practices associated with a particular creed, denomination, or sect. Moreover, religiousness was seen as consisting of two aspects; namely, the intrinsic and extrinsic religiousness. Intrinsic religiousness refers to a personal experience in which the individual searches for the truth (i.e., religious faith) that may be applied to living life fully, while extrinsic religiousness refers to a rule-oriented religious system that seeks external gain from religious experiences, such as fulfilling one's social needs to include social status and social interaction.

With the rise of secularism, multiculturalism, and disillusionment with religious institutions came a shift toward the concept of spirituality. Current definitions of spirituality have ranged widely, depending on one's theoretical or professional perspective. For social scientists, spirituality involves a search for the sacred. Individuals who practice psychotherapy, on the other hand, tend to view spirituality as the subjective experience of the sacred, while health care educators and professionals consistently assess spirituality as a person's internal sense of purpose, coherence, and a search for meaning in life. Despite the lack of a consensual definition, many analysts include the elements of transcendence, meaning and purpose in life, inner strength, connectedness, higher power, and caring relationships into their perceptions of spirituality. In attempting to consolidate such diverse views, one analyst recently defined spirituality as a motivational-emotional construct that refers to a desire to seek and to maintain meaningful integration within oneself (innerconnectedness), with other people and the world (human compassion), and with a sacred force outside oneself (connectedness with nature). In effect, spirituality is a personal quest for ultimate meaning, for a relationship with significant others, and with a transcendent force or higher power.

Thus, spirituality and religiousness are interrelated but not identical concepts. Although religiousness may be an outward manifestation of spirituality, spirituality can exist in the absence of religiousness, while religiousness does not guarantee a developed spirituality. In a study of self-definition of spirituality and religiousness reported during 2002, it was found that 32% of university students indicated they were both spiritual and religious; another 32% indicated that they were spiritual but not religious; 8% indicated they were religious but not spiritual; and 28% indicated they were neither spiritual nor religious. This study reveals the extent of public awareness and consciousness surrounding spirituality and religiosity and the need to clearly distinguish between them. Toward this end, the concept "humanistic spirituality"

is used here to refer to spirituality, and the concept "religiosity" to refer to the traditional definition of religiousness.

Measurement of Spirituality

The renewed perspective on the conceptualization of spirituality brings with it the challenge of constructing measures that are accurate and precise (reliability) and that the scale measures what it is claimed to measure (validity). Much of the impetus for measurement from the health sciences was spearheaded by the Fetzer Institute. In response to this initiative, a number of unidimensional and multidimensional scales of religiosity and spirituality were developed. To assess the unidimensional nature of spirituality independent of religiosity, the Spiritual Meaning Scale, a 20-item measure of theistic ("The goals of my life grow out of my understanding of God") and nontheistic ("My spiritual beliefs give meaning to my life's joys and sorrows") spirituality, is used. Another 20-item scale, the Spiritual Well-Being Scale, measures religious well-being (a sense of well-being in relation to God) and existential well-being (one's sense of meaning, purpose, and satisfaction with life). These measures reflect the contemporary distinction made between the constructs of religiosity and spirituality.

Two multidimensional measures extend the construct of spirituality. The 28-item Spirituality Assessment Scale (SAS) consists of four dimensions: purpose and meaning in life, inner-resourcefulness, unifying interconnectedness, and transcendence. A 24-item Spiritual Transcendence Scale (STS) consists of three dimensions of humanistic spirituality: innerconnectedness, human compassion, and connectedness with nature. The new scales reflect significant improvements in the conceptualization and measurement of religiosity and spirituality. The authors of all scales report good to very good psychometric properties. One of the key empirical contributions is the demonstration that measurements that claim to measure spirituality do, indeed, measure spirituality independent of measurements of religiosity. Moreover, the personality dimension of "openness to experience" is positively related to measures of spirituality, but is negatively related to measures of religiosity. Such findings provide some support for the notion that spirituality embraces freedom of expression, whereas religiosity tends to inhibit it, leading to the conclusion that spirituality and religiosity are distinct constructs that need to be assessed separately.

Spirituality, Health, and Death Attitudes

In recent years, empirical studies have identified significant links between spirituality/religiosity, physical/mental health, and death attitudes. Death poses an abstract and uncertain reality of the human experience. Spirituality serves as one means to address existential concerns associated with one's death and the attitude one takes toward death. But empirical investigations of spirituality and attitudes toward death are few in number, and early studies were conducted within the intrinsic/extrinsic religiosity paradigm. These studies show that intrinsic religiosity (religious belief) is associated with low death anxiety, whereas the relationship of extrinsic religiosity (religious behaviors) to death anxiety is nonsignificant or even positively related to fear of death. More recent research pertaining to negative and positive attitudes toward death in older adults shows that an intrinsic religious orientation is positively related to acceptance of death, while an extrinsic orientation is positively related to fear of death and death avoidance. More importantly perhaps, purpose in life rather than intrinsic or extrinsic religiosity is found to be positively related to subjective well-being and negatively associated with fear of death and death avoidance.

Intrinsic religiosity may be considered to be more closely related to spirituality in that intrinsic religiosity reflects a belief in, and a commitment to, a higher power that provides a sense of meaning and purpose in life. This suggests that it is the strength of the faith, the belief, or the commitment inherent in intrinsic religiosity that is more important in alleviating death anxiety and fear of death than are religious affiliations or religious behaviors per se. A similar pattern emerges when the relative contribution of spirituality and religiosity to death attitudes are examined; that is, spirituality is negatively related to death anxiety, whereas religiosity is not related to death anxiety. In addition, recent studies have shown that the construct of meaning in life mediates the relationship between spirituality and subjective well-being, whereas no such mediating effects are found for religiosity.

Spirituality, Loss of Significant Other, and End-of-Life Care

Spiritual exploration and spiritual questioning often arise in the context of the loss of a significant other through bereavement and grieving processes or with one's own impending death. The individual's desire to understand their location in the order of things leads to a need to feel connected with others. Spirituality reflects a self-directed approach and quest for personal meaning and answers to spiritual questions that assist with alleviating existential angst. Indeed models of health care, palliative care, and hospice care recognize the importance of spiritual issues.

Spirituality is an essential component in the care of patients with life-threatening illnesses and those who are dying. Their beliefs and values can contribute to a fuller self-understanding of their illness. Furthermore, in the caregiving and care-receiving relationship, it is not only the patient's spirituality, but also that of the caregiver that is important. Caregivers who understand their own spirituality can offer compassionate care and foster a sense of connectedness with patients that can facilitate the healing process. The biopsychosocial-spiritual model of care, utilizing the holistic approach to all four dimensions of the human experience, offers an essential pathway for integrating spirituality into health care. However, it is important to enhance spiritual care education and training in interdisciplinary spiritual care practices.

In summary, spirituality and religiosity are related but not identical constructs. They are similar in that both involve a search for the sacred or a higher power. They are different in how the search for the sacred is actualized through a personal search for meaning versus organized religious beliefs, rituals, and practices. Spiritual exploration and spiritual questioning are particularly salient in the context of existential concerns with personal death, the loss of significant others, and life-threatening illnesses. The biopsychosocial-spiritual model of care offers a promising approach to address these issues.

Spontaneous Combustion

Spontaneous combustion occurs when an object self-ignites. The cause may be chemical, as when lithium oxidizes explosively in water, or biological, as when a haystack catches fire due to heat generated from bacterial fermentation. There is no scientific evidence that the human body can self-ignite. However, spontaneous human combustion (SHC) as an alleged cause of death has a long and controversial history. If true, the mechanism of ignition is mysterious and challenges what we know about the human body.

Cases accredited to SHC tend to have features in common. Most victims are female. Many are overweight, alcoholic, and have a mobility dysfunction or disabling illness. Usually there are no witnesses to the combustion and no calls for help are heard. The torso is badly burned, while

extremities, such as the lower legs, are left intact. The immediate environment suffers little damage although a foul-smelling yellow oil may surround the body. Often there is a significant time lapse between the victim being last seen alive and the finding of their charred remains.

Apart from possible accounts in the Bible, the first description of SHC in Western culture has been attributed to Danish anatomist Thomas Bartholin (1616–1680), founder of the journal *Acta Medica et Philosophica Hafniensia,* who described the case of a Parisian woman incinerated in her sleep while the straw mat on which she lay sustained little damage. In 1763, Jonas Dupont collected such stories in *De Incendiis Corporis Humani Spontaneis,* raising the public profile of the phenomenon.

Public interest in SHC has been utilized by writers as a dramatic literary device. Possibly the earliest example can be found in Charles Brockton Brown's (1771–1810) novel *Wieland* published in 1798. The most famous is the death of Mr. Krook in Charles Dickens's (1812–1870) *Bleak House,* first published 1852–1853 and forming part of the debate about SHC that raged in 19th-century England. SHC has been the subject of sustained interest in more recent times since the death of Mary Reeser in Florida, in 1951, at the age of 67, popularly accredited to SHC.

Seventeenth and 18th-century explanations for SHC favored alcoholism as the cause, believing (erroneously) that "alcohol-saturated" flesh was readily combustible. The more speculative contemporary explanations include kundalini fire, geomagnetism, ball lightning, and force fields from high-tension wires. Quasi-biochemical accounts such as "pyroton" particles initiating a nuclear chain reaction within the human body, ignition of cellular hydrogen and oxygen, and mechanisms associated with phosphorous metabolism have been dismissed by scientists as, at best, misinformed. Two explanations based on known scientific principles have met with less general skepticism and account for at least some of the phenomena associated with SHC: the static flash fire hypothesis and the candle or wick effect.

The human body can generate static electricity, and Professor Robin Beach, formerly of the Brooklyn Polytechnic Institute, suggested that some people can generate up to 30,000 volts at a time, which may singe or burn clothing on discharge. Moreover, there is some evidence that static discharge from people may ignite fires in some highly flammable environmental conditions. However, Beach's research demonstrated that the human body can hold an extremely high charge of static electricity without harm, so it is unlikely to cause a person to self-ignite in the way implied by SHC.

Possibly the strongest candidate explanation is that clothes saturated with melted human fat from an already burning body function like the wick of a candle, maintaining a slow but steady burn that cremates the fattier parts over several hours. Dr. John deHaan, a Fellow of the American Board of Criminalistics, demonstrated the wick effect on the BBC One program QED in 1998. The body of a dead pig—an animal with a similar fat content to the human body—was wrapped in a blanket and set alight using a small amount of petrol. The experiment showed that the pig's bones could be incinerated within about five hours.

The wick effect requires external ignition, an ineffectual and possibly slow reaction on the part of the victim, and time and poor ventilation to allow the smoldering flame to incinerate parts of the body. In cases of alleged SHC, these conditions are often met. Cigarettes, cigars, or a pipe are sometimes found near the body and an accelerant reaction from alcohol spillage or from highly flammable clothing is possible. Failure to extinguish the original flame can be accounted for by an alcohol- or drug-induced stupor, old age, disability, or death prior to incineration, as when the victim had suffered a heart attack or when fire may have been used to cover a murder. Moreover, victims are often socially isolated and found in poorly ventilated rooms. The ignition point of human fat is relatively low, and a human body can be incinerated at temperatures much lower than used in crematoria given time, poor ventilation, and porous bones (as in osteoporosis) with a smoldering fire unlikely to spread to surrounding areas or to draw immediate attention. The wick effect also explains why it is usually the fattier parts of the body that sustain the greatest damage.

Alleged cases of SHC are rare today. Forensic science is better able to explain immolations and it is likely that with additional, accurate information, many cases of alleged SHC would be explainable as tragic accidents or murders. To be taken

seriously, unusual claims require unusually strong supporting evidence, and the onus is on the exponents of SHC to prove the phenomenon beyond reasonable doubt. Until then, it seems prudent to follow the dictum of Occam's razor, which counsels acceptance of the simplest, most parsimonious explanation. Moreover, it is known that stories lending themselves to a dramatic interpretation, such as an unusual and gruesome death, are often developed in this direction in the telling. Hence, until a mechanism is proven for human self-ignition, it seems reasonable to assume that an external source is responsible.

Spontaneous Shrines

Leaving flowers, candles, teddy bears, hearts, or cards on sites where people died a violent death has become a regular practice since the 1990s, at least in the Western world. In academia, it has become custom to refer to such commemorative sites as "spontaneous shrines," a term coined by Jack Santino. Murders, traffic deaths, work-related accidents, terrorist attacks, or disasters of human or natural origin may trigger people to bring attributes to the place of mischief in commemoration of the deceased. Other deaths that may evoke similar responses are the deaths of public figures (celebrities, royalty, politicians), although spontaneous shrines will generally appear on places associated with the deceased rather than on the place of their death.

All spontaneous shrines, whatever the reason of their taking shape, share the public dimension: exceptional deaths of ordinary people in the public domain as well as natural deaths of public people in the confinement of their private domains are "public events." This explains why people without a formal or personal relationship with the deceased may feel invited or compelled to express their grief, anger, or empathy in public. Many of the attributes that constitute spontaneous shrines are also placed on graves. However, spontaneous shrines differ from graves in three important respects. First, there are no bodies. Second, the public dimension sets spontaneous shrines and related ritual apart from funeral ritual, which is usually confined to the intimate sphere of friends and relatives. Third, spontaneous shrines arise on neutral, public places that are not formally reserved for mourning.

Disagreements Over Terminology

Santino chose the adjective *spontaneous* to highlight the unofficial nature of the commemorations performed. No authorities or institutional organizations initiate or encourage the erection of spontaneous shrines; instead, such sites result from people's personal motivations. Some scholars have objected that spontaneous shrines are not the outcome of "instantaneous" impulses, however, and approach spontaneous shrines as ritualized practices. In this view, spontaneous shrines, irrespective their unofficial nature, arise along the lines of what people deem to be the most appropriate and customary response to violent deaths. To avoid misinterpretations, scholars often choose other adjectives instead of *spontaneous,* most of which emphasize the transient nature of such sites. *Makeshift memorials*, *ephemeral memorials,* or *temporal memorials* are other expressions to refer to the same phenomenon, and may also be used in common language.

Approaching these sites as places of communion between the dead and the living, Santino prefers the term *shrine* above *memorial*. Shrines share this ability to offer communion with all other material objects and places that carry memories of the dead. Therefore, this communal quality is not specifically restricted to shrines. Monuments, memorials, and graves also connect the dead with the living through a physical location. Understanding why certain places continue to attract people over long periods of time while others pass into oblivion requires social, cultural, religious, and political

contextualization. Many scholars writing on the subject prefer the term *memorial* above *shrine* because the religious connotations of the term may contain the danger of obscuring significant differences in practice, form, and experience with unambiguously religious sites.

Public Mourning

Public mourning, of which spontaneous shrines are a contemporary expression, indicates the impact that certain deaths have on society. Deaths that may bring about large-scale public involvement are the deaths of public figures and the multiple deaths of ordinary people in shocking events. The deaths of celebrities, sports stars, singers, or politicians may deeply impress fans or supporters, particularly when perceived as untimely. In the case where a public figure dies a violent death, the societal impact is often broader and more intense, and may inspire more people to participate in the public mourning.

The massive response to the death of Princess Diana in 1997 brought the topic of spontaneous shrines inescapably to the attention of social scientists, journalists, and the wider public. The images of the immense heaps of flowers and the mourning crowds at the gates of Kensington Palace found their way around the globe. Many, including but not limited to British people, wondered how to understand this apparently unprecedented outpour of public grief. As a consequence, the mourning for Princess Diana has been quite extensively researched from a variety of angles. Much writing on spontaneous shrines takes the Princess' death as a starting point, historically as the first example that set the trend or rhetorically to introduce the subject. An unusual combination of ingredients, that is, the Princess' high media profile, the bizarre circumstances of her death, the criticism toward the royal family, and the permanent media coverage, added up to a public response of new scale and intensity. Yet spontaneous shrines have occurred earlier, for example, as part of the response to the murder of the Swedish Prime Minister Olaf Palme in 1986.

To a certain extent "the public" has always been present in the ritual following upon the death of public figures. Traditionally, the role of the public was rather passive and limited to witnessing the funeral procession. Spontaneous shrines and related ritual are different in resulting from an uninvited, active involvement of private citizens outside any formal protocol.

Since the mid-1990s, an increasing number of violent incidents or disasters that brought about the deaths of—smaller or larger—numbers of ordinary people have been commemorated through spontaneous shrines and other public mourning ritual. Examples of events that received worldwide attention were school shootings, the terrorist attacks on the World Trade Center and the Madrid Trains, and the 2004 Southeast Asia Tsunami. Important for the public to get involved in the mourning is the extent to which a death or multiple deaths attract media attention, and the way the media frame the incident as a societal issue. Spontaneous shrines often coincide with media hype, which is not to say that the sentiments are void or meaningless. Mass media also play a vital role in shaping ritual and disseminating new formats of mourning and commemorating.

Roadside Memorials

Most spontaneous shrines are roadside memorials. These memorials for traffic casualties are generally initiated by the victim's close friends and family, without the involvement of a wider public. Leaving aside accidents that are exceptional in, for instance, the number of deaths, media coverage of traffic tragedies generally remains local and low profile. As a phenomenon, roadside memorials are gaining in importance in many Western countries. Nevertheless, to place this development in proper perspective, it should be kept in mind that roadside memorials are erected for only a fraction of the world's annual traffic casualties.

Roadside memorials are often interpreted as continuations of Catholic memorial crosses. However, the present-day roadside memorial is not restricted to Catholic areas at all, and there are important differences between the two memorial practices. Memorial crosses were erected for those who had died unexpectedly along the road, and consequently had to appear unprepared before God's throne. Short texts on the cross encouraged passersby to pray for the salvation of the unfortunate's soul. Today's roadside memorials are not based on such theological considerations. Instead, they articulate the increasing experience of traffic

death as unnatural, particularly when it strikes young people. Although frequently used, the cross has for many become rather a sign for death, loosened from its original religious meaning. This demonstrates the need for caution in explaining present-day expressions of mourning as a continuation of earlier practices in a new context.

Many roadside memorials start out as a few bunches of flowers and some candles along the road, demarcating the place of the victim's death. Yet the effort it takes to maintain a roadside memorial that consists exclusively of ephemeral objects for an extended period of time is a problem that comes with any spontaneous shrine and makes many people turn to more solid solutions. Crosses, slabs of stone, boulders, pebbles, decorated posts, or perennial plants, sometimes in combination with a plaque, are the main constituents of many roadside memorials. In some countries, it has become customary to include the tree against which the victim crashed in the memorial, while elsewhere these trees may become the target of people's grief and anger, and are cut or damaged.

In order to keep control of the growing number of more or less permanent roadside memorials, many local and national authorities have developed rules and regulations about their size, duration, maintenance, and location. Roadside memorials also evoke objection and aversion. One common objection is that roadside memorials distract the attention of drivers, and therefore are dangerous. Another is that it is disturbing to be confronted unsolicited with death or the sorrow and grief of others. The regulations imposed—restricting diversity and visibility—are often at odds with the desire of the bereaved for an individual, self-styled expression of their emotions. However, in spite of all striving for individuality, roadside memorials are ritualized practices in which an individual touch is but one requirement.

Moreover, when trying to understand the current proliferation of roadside memorials, it is important to realize that the horrendous fact of the daily road deaths and injuries alone does not offer a sufficient explanation. In most Western countries the traffic "death toll" has decreased drastically over the last 30 years. Apparently, popular sentiments are not rooted in statistics. Consequently, roadside mourning and related forms of public commemorative ritual are specific for our era, and therefore should be analyzed in a broader societal context.

Rituals of Protest

Spontaneous shrines are part of a broader repertoire of mourning ritual. In many cases, the bereaved, or others who feel involved with the tragedy, hold a wake or service at the memorial site or organize a (silent) march to express their grief and anger. Next to these concrete public performances, web-based condolence registers and virtual memorials also become common elements of the ritual repertoire of public commemoration.

Violent death may happen unpredictably, and the reactions of the public and the subsequent media coverage can be anticipated. Yet, we should not conclude from the similar appearances of such responses in many places of the world that they imply similar intentions or meanings. Behind the shared repertoire lie different worlds of messages, morals, and politics that are deeply embedded in local societies.

Apart from being expressions of mourning, spontaneous shrines are also material articulations of political messages or even protests. In addition to their unorganized "coming into being," this is another significant dimension in which spontaneous shrines differ from graves and other places that are specifically destined for mourning ritual. Although graves and spontaneous shrines both prolong the social presence of the deceased, in the case of graves this remains limited to the personal perception shared by family and friends (deceased celebrities excepted). Spontaneous shrines are always also material testimonies of the cause of the victim's death. A spontaneous shrine imposes a more societal or political identity over the deceased's personal identity, namely that of being a victim of a specific type of social evil or (natural) disaster. By bringing attributes to the place of mischief, signing a condolence register, participating in a wake, or joining a march, the participants make public statements about a specific, contemporary, moral, and political issue. Through the ritual, the participants present themselves to the outside world as a moral community, implicitly excluding the evil ones from this community.

Stephenson's Historical Ages of Death in the United States

People collectively construct meanings, images, and rituals for coping with the mystery and inevitability of death. In the United States, as in all societies, these collective images and rituals for coping with death have changed drastically over time. Beginning with the original New England colonies during the 17th century, John Stephenson, in *Death, Grief, and Mourning: Individual and Social Realities,* demonstrates how the images of death and the rituals associated with death and the dying process proceeded through three stages: the age of sacred death, the age of secular death, and the age of avoided death.

John Stephenson describes how over the last four centuries, the collective meaning of death shifted in the United States. Thus, the collective interpretation of death evolved from a sacred process, embedded in the Puritan eschatology, to a secular process, premised on science. Then, as the U.S. society transitioned into modernity, individuals institutionalized and bureaucratized the dying process while removing it from public life. The three historical ages of death in the United States represent not static points in history, but rather dynamic processes wherein culture and institutions intersect. This entry highlights Stephenson's assessment of the social processes that influenced the image and rituals of death within each of the three historical ages of death.

Collective Image of Death and Social Processes

Exactly what death means for society is contingent upon the social context. Death is understood in terms of the value system held by members of the social environment. Individual images of death reflect the collective image of death. It is this collective image that defines each historical stage of death in the United States, a collective image that is associated with the social, political, economical, cultural, and demographic context and processes.

Age of the Sacred Death

Stephenson indicated that the sacred age of death in the United States arose in the Puritan colonies of New England during the early 17th century. The religious meanings associated with death and the dying process caused death to have a sacred meaning. People died as the result of sin, and upon dying, they had to account for their sins on earth. During this stage of death in the United States, people understood why they died and what was to be expected in the afterlife.

Early Puritan society consisted of small, tight-knit communities where religion and family were central to social life. Low life expectancy rates resulted from high rates of disease, occasional epidemics, and poor health care in the colonies. Infant and child mortality rates were high. At least one out of four of the infants who survived their 1st year did not live to see their 10th year. Considering the closeness of the Puritans and the high mortality rates, death rarely went unnoticed. Death was always on public display within everyday life.

Puritan beliefs defined the collective image of death during this period of sacred death. Central to the Puritan doctrine was the notion that only a few people would enter the Kingdom of God, and only God knows of those chosen few. With afterlife predetermined, individuals had no guarantee that they would enter the Kingdom of God upon their death. Thus, death was a source of extreme fear and anxiety. Not only did people fear death, religious doctrine mandated fear. Therefore, the

dying process was a time of severe terror of one's impending doom and eternal damnation.

Although grim, this collective image of sacred death provided a clear explanation for the dying process, death, as well as the afterlife. Neither death nor the afterlife was a mystery for the Puritans. In accordance with the Puritan eschatology, suffering was a condition of the earthly life, whereas heaven was the place free of suffering. One needed to work hard and live a meager life while devoted in worship.

While the collective image of death during the age of sacred death manifests in the rituals for death, so too did the rituals during dying process, the funeral ceremony, and the rituals for disposing of the body shift in accordance with these collective images of death. Individuals cherished the physical life and feared the afterlife during the age of the sacred death. Therefore, the focus of the dying process was on the dying individual rather than the bereaved survivors. Death was a reality observable in daily life, was rarely sudden, and therefore, people usually knew of their immanent death well before their final moments. Furthermore, the dying process during the age of sacred death was a public ceremony. Upon the awareness of the individual's impending death, the room of the dying would transform into a public place where friends, family, acquaintances, and other members of the community would visit with the dying.

During the age of sacred death, the family prepared the deceased for burial, delivered the body to the gravesite, and buried the body. Survivors did not mark graves with gravestones because the grave was only thought to be a temporary holding area for Judgment Day. Survivors avoided any recognition of the grave or memorial of the deceased as it emphasized the earthly life, not the spiritual life. Rather, the public acknowledgment of the deceased occurred during the sermon on the Sunday following the modest burial.

Age of the Secular Death

The age of the sacred death did not give way to the age of secular death until the turn of the 19th century. Stephenson enumerated several factors that led to the transition from the sacred death to the secular death. At the turn of the 19th century, the Industrial Revolution marked the introduction of factories resulting in mass urbanization and the subsequent rise of the U.S. metropolis. As the United States moved toward modernity, it brought with it prosperity; wealth increased, the quality of life rose, infant mortality rates slowly declined, and life expectancy increased. Science and technology replaced religion as the authority of the day. The political power of the Protestant Church and its doctrine declined. And as wealth and commerce increased, people began looking toward the economy for security rather than the family and community as in times past.

As social, political, and economic life in the United States underwent profound changes, so too did the collective image of death. People believed death no longer resulted from sin. Because science had the tools to control nature, people no longer believed God controlled human destiny. Consequently, religion had less influence on the collective image of death. As U.S. values shifted from religion to science, the underlying ideologies associated with death also shifted from religious to scientific. During the secular age of death, individuals adopted scientific logic as the standards, and thus, life and death shed its sacred meanings. People reinterpreted death as simply a natural, unpredictable occurrence that provided no resolution for the survivors.

Furthermore, by the turn of the 19th century, as the collective image of death and life lost its sacred meaning, the collective image of God began to shift—even within the Protestant Church. Whereas during the sacred age, God was perceived as angry and vengeful, He was now seen as a kind, gentle, and forgiving God. This new image of God took the sting out of death because everyone—even the wretched sinner—could enter into the Kingdom of Heaven. Because death assured a person's place in heaven, death no longer represented terror and angst, but rather a joyous and celebratory occasion.

The meaning of cemeteries shifted during the secular age in that cemeteries provided inspiration and immortality for the living. They were public displays, serene garden-like areas with highly decorative gravestones and detailed imagery and inscriptions representing eternal peace and heavenly splendor.

This shift from the collective image of the sacred death to the image of the secular death produced shifts also in the focal point of death, from the

deceased individual to the bereaved survivors. People thought that with diligence and hard work, everyone could achieve the American Dream. Because humanity was now perceived as its own provider, individuals had to provide for their families both in life and in death. Therefore, individuals sought rational ways for providing such security through earthly, rational means, such as savings, life insurance policies, and trust funds.

The age of secular death marked a time of significant mourning rituals. The increasing secularism coupled with the increasing pace of urban life and the expansion of the metropolis resulted in the decline of emotional support within the family and community and an increase in social isolation and alienation. The shift of focus from the deceased to the survivors as well as the inconsolable sorrows of losing loved ones contributed to the increase in elaborate mourning rituals during the age of secular death. The survivors expected to spend long periods in mourning for loss of their loved ones.

The funeral ceremonies during the age of secular death were elaborate, depressing, and poignant public events that focused on the bereaved survivors. Survivors displayed their sorrows not only through emotions, but also through the adornment of symbols of grief, such as solid black clothing, armbands, or badges. Furthermore, with wealth and materialism, funeral ceremonies became venues for displaying social status.

As the popularity of elaborate funeral ceremonies increased over the course of the 19th century, a division of labor arose for managing the death rituals. By the end of the 19th century, these rituals for death were a lucrative industry. In the early 19th century, the family began relinquishing the burial preparations to skilled nurses, furniture stores built and sold coffins, and funeral directors or undertakers managed the funeral ceremony and burial. Whereas the family ultimately prepared the deceased for burial, delivered the body to the burial site, and buried the body during the age of the sacred death, during the age of secular death the family outsourced the logistics of the funeral ceremony and burial to specialists.

Cemeteries, too, reflected the shift from the deceased to the bereaved survivors. While often located in isolated areas close to a church during the sacred age, during the age of secular death, cemeteries became memorials for the deceased was well as material items to assist in the grieving process. And while uncommon during the age of sacred death, gravestones during the secular age depicted the grief and sorrow of the survivors through inscriptions about the survivors of the deceased or in remembrance of the deceased.

Age of the Avoided Death

The end of World War II signified, among other things, a transition from the age of secular death to the age of the avoided death—the age of death in contemporary America. According to Stephenson, the collective image of the secular death remained the same as in the previous era. What makes this era unique from previous ones is that American society removes death completely from everyday social life. The collective image of death as taboo and, consequently, the removal of the dying process and death from public life through the institutionalization of all aspects of death and the dying process characterize the age of avoided death in the United States.

Death no longer is an everyday reality. The institutionalization and bureaucratization of death that began in the previous era came to fruition during the mid-20th century. Hospitals, hospices, and nursing homes steadily replaced the role of the family and community in the dying process, and morgues, mortuaries, and funeral homes steadily replaced the role of the family and community once death occurred. Whereas in previous eras, the dying process was a public event, death during the age of avoided death occurs behind closed doors in institutional settings, where the dying usually dies alone. Furthermore, the inordinate amount of military and civilian casualties resulting from the two World Wars during the first half of the 20th century marked a cultural shift in the grieving and mourning rituals in the United States. Whereas the rituals for coping with the loss of loved ones involved highly emotional, public ceremonies and long periods of mourning during the age of secular death, survivors now avoid grief and mourning rituals.

However, these structural factors alone do not fully explain why individuals avoided death. As the structural factors changed, so too did American values. The current image of death stands in stark contrast with many core American values, among them a belief in the science and technology for

mastering nature, success, progress, materialism, and rationality. First, as science and technology can, at best, extend the dying process, death represents the failure of science and medical practitioners. Death contradicts the notion that humans can solve everything and conquer nature through science and technology. Second, as people view death during this era as a natural process, it is devoid of meaning. Death and dying therefore result from individual failure—the inability to maintain oneself. Third, a principle component of success in the United States is material wealth. Everything is possible as long as you have the money to pay for it. Death contradicts this belief. All the money in the world cannot exempt anyone from death. Finally, as death is irrational, it clashes with the American value of logic, explanation, or method.

As individuals are unable to reconcile the image of secular death with the American value system, the thought of death produces fear and anxiety. Rather than coping with these irreconcilable differences, contemporary American society hides the dying process behind the institutional walls of the hospital, hospice, and nursing homes. Highly formalized bureaucracies such as morgues, mortuaries, and funeral homes now handle the death rituals.

However, the avoidance of death in contemporary America does not end with the institutionalization of death and dying. Individuals, even those dying, should ignore death, or even deny its inevitability, at all costs. When informed of their impending death, the dying should accept it discreetly. Prohibited is excessive emotional behavior, courageous and dignified are those people who die silently.

Similarly, survivors must show a lack of emotion, demonstrating a courageous, strong, and honorable front. Survivors can only express grief in private or during institutionally prescribed times, such as during the funeral ceremony. Talking about death is morbid and negative; rather, individuals should ignore the dying process as well as death.

The funeral ceremony within the age of avoided death makes death appear avoided. The funeral director has the task to breathe life back into the deceased, if only to give the impression that the person is sleeping. With embalming methods and cosmetics, the deceased appears alive for the viewing, to look just as good—if not better—than they did before they died. Subtlety, too, is the defining feature of the contemporary cemetery. As death is now a cultural taboo, no longer do cemeteries use elaborate statuaries or tombs.

Subintentional Death

Within the death and dying literature, subintentional is defined as indirectly or unconsciously causing one's own death. Many experts such as Normal Farberow, cofounder of the Los Angeles Suicide Prevention Center, believe that subintentional death and suicide exist along a continuum. At one end of the continuum is direct, overtly

suicidal behavior. The individual communicates unhappiness and intentionally causes self-death. The actions are unequivocal, and often substantiated by a written note or a verbal declaration. At the other end of the continuum are indirect self-destructive behaviors that may shorten life whether or not conscious suicidal intent is present. These individuals may have no intention to die and may not consider themselves to be suicidal. The actions are equivocal, and include risk taking in driving and sports; poor physical care including medical noncompliance, disregard of preventive advice, and neglect; nonlethal physical destruction, such as self-punishment and self-mutilation; unprotected sex; pathological gambling; and abusing alcohol or drugs. It is important to examine theoretical understandings of subintentional death, research on this important topic, and society's attitudes toward subintentional death.

Theories

Theoretical understandings of subintentional death began about the early 1900s, when sociologist Émile Durkheim classified indirect self-destructive behaviors as embryonic forms of suicide. The psychiatrist Sigmund Freud considered ordinary mistakes, errors, minor accidents, bungled actions, slips of speech, and other cases of forgetting to indicate unconscious suicidal wishes. Robert Firestone posited that self-limiting, self-destructive behaviors are based on powerful self-hatred and negative self-attitudes incorporated by the child during formative years.

Edwin Shneidman in 1968 coined the term *subintentional death* and developed four subtypes. Death chancers leave the outcome to chance, such as fundamentalist snake handlers and those who practice autoerotic asphyxia. Death hasteners bring about their own deaths through lifestyle choices and treatment noncompliance; they disregard medical recommendations, such as eating excessive sweets although they are diabetic. Death experimenters pursue altered consciousness, such as chronically abusing alcohol or drugs. Death capitulators give up, such as individuals who die after a voodoo curse.

Developmental theorists, such as Diana Baumrind, note that risk taking is part of normal adolescence. Developmentally constructive risk that promotes growth includes adaptive experimentation, which builds confidence, enhances competence, develops initiative, promotes autonomy and mastery, and hones skills essential for the transition to adulthood. In contrast, pathogenic, deviant, life-threatening risk taking potentially jeopardizes health and life.

Biological theories attribute risk taking to hormonal influences and genetic predispositions. In support of this understanding is that testosterone levels rise during adolescence; at the same time, risk taking increases. In addition, alcoholism runs in families, and risk taking appears to do so as well.

Psychological and cognitive theories note that optimistic expectations influence how people perceive risk and feel invulnerable. People with high tendencies toward sensation seeking take physical and social risks simply for the sake of the experience. For example, they might enjoy bungee jumping. Further, compared to others, they expect more positive outcomes, process novel or intense stimulation differently, have higher thresholds for pain, are more susceptible to boredom, and have unusually low levels of arousability.

Research Findings

Some research exists on subintentional death. A longitudinal analysis by Jan Neeleman in 1998 of a general-population birth cohort born in 1946 indicated that conduct disorders and aggression, and to a lesser extent emotional instability, raised the risk not only for suicide but also for premature death from accidents as well. This finding is consistent with the hypothesis of a continuum between subintentional and intentional self-destructive behavior.

Several questionnaires inform research on subintentional death. The 84-item Firestone Assessment of Self-Destructive Thoughts (FAST) includes 11 levels of progressively self-destructive thoughts (e.g., You're incompetent, stupid). The FAST has uniquely pragmatic instructions to report how frequently a person has various negative thoughts directed toward themselves. The second-person format illustrates elements of a self-destructive process that may have been partially or completely unconscious.

Designed for a specific population, the 20-item Harmful Behaviours Scale (HBS) developed by Brian Draper and colleagues includes a broad array of behaviors, such as refuses to eat or

drink, irrespective of their motivation. In one study where nursing home staff completed the HBS, residents fell into four groups: aggressive or resistant, food refusal, behaviorally disturbed, and nonsymptomatic. The behaviorally disturbed group engaged in a widespread combination of direct and indirect self-destructive behaviors and displayed other behavioral and psychological symptoms of dementia. In contrast, the food refusal group had the most cognitive impairment, but no higher depression or suicidal ideas. Among nursing home residents, indirect self-harmful behaviors were most often associated with dementia.

Also, the How I Deal With Things Scale developed by Martha Burt and Bonnie Katz asks women to rate how frequently they used 33 different coping behaviors in dealing with adult sexual assault. Its Self-Destructive subscale is comprised of eight items about behavioral acting out or escapist coping (e.g., Drank a lot of alcohol or took other drugs more than usual). Self-destructive coping is associated with trauma symptoms following sexual assault.

Societal attitudes toward subintentional death are not necessarily grounded in theory or research. In general, people's attitudes toward subintentional death differ from their attitudes toward suicide. Except in rare cases of altruistic suicide and terminal illness with intractable pain, people typically condemn suicide and view suicidal people as psychiatrically disturbed. With subintentional death, in contrast, people respect individual right to choose, and may even glorify those who survive extreme adventure-seeking behaviors.

The idea in the term *subintentional death* is that the deceased person plays a role in hastening the death, such as exercising poor judgment by driving a car without bothering to fasten the seat belt. However, the distinction between intentional and subintentional death is not always clear, such as some cases of overdose where it is not clear whether the person knowingly ingested too many pills.

Sudden Death

Sudden death involves the unexpected or untimely death of an individual. The term is commonly used to refer to sudden cardiac death—a natural death from cardiac causes, heralded by an abrupt loss of consciousness within one hour of the onset of acute symptoms. Other forms of sudden death may be noncardiac in origin. Examples include respiratory arrest, toxicity or poisoning, anaphylaxis, or trauma.

The sudden cardiac death concept incorporates the features of natural, rapid, and the unexpected. It does not specifically refer to the mechanism or cause of death. Common examples of unexpected natural deaths include deaths by heart attack, stroke, or ruptured aneurysm, death from rapidly progressive infectious diseases, sudden infant death syndrome, postoperative complications, pregnancy and postpartum, and natural disasters, including earthquakes, hurricanes, and floods.

Some sudden losses are the result of intentional acts, such as suicide and homicide. Also, deaths from bombings and acts of war and terrorism are intentional acts, although direct contact with the intended victims is not always present. Other deaths, such as vehicular homicide due to reckless or drunken driving, have a lesser degree of intentionality. The individual responsible for the death made a choice that resulted in another's death, but there was no premeditation. Finally, in the case of sudden death as a result of accident, there is no clear intentionality.

Some sudden losses may have a degree of expectedness. For example, the heart attack of someone at risk or the sudden loss of someone struggling with a life-threatening illness, even supposedly in recovery, may not be completely unexpected. Suicide is commonly described as a form of sudden, unexpected death. This view evolves from suicide survivors who report that they often feel unprepared and describe the event as a devastating emotional blow. Although suicide is sudden, the death is not always unexpected. This is because the decision to take one's life is frequently preceded by depression and psychiatric disturbances, the occurrence of diverse negative stressful events, and suicide warnings, threats, and/or attempts. Most individuals who commit suicide provide cues about their intention, and many suicide survivors recognize this to be the case.

Incidence of Sudden Death and Survivorship

The major forms of sudden death rank among the major leading causes of death in the United States today. In 2005, heart disease was the leading cause of death. Cerebrovascular diseases, including strokes, were the 3rd leading cause of death, while accidental death ranked 5th, suicide was 11th, and homicide ranked 15th among the leading causes of death.

The impact of sudden death on the lives of survivors is widespread. With nearly 1 million sudden deaths each year, researchers estimate that each sudden death affects 3 family members on average and 7 to 10 close relatives and other significant others. Based on these estimates, sudden death impacts 10 to 12 million survivors annually in the United States.

The Aftereffects of Sudden Loss

The suddenness of death can raise a number of complex issues for survivors. Research findings suggest that sudden death leads to more immediate and long-term coping problems among the surviving family members than deaths that are anticipated. Indeed, sudden death has been associated with frequent and persistent depressive syndromes, the onset of new illnesses or the exacerbation of existing illnesses, and increases in health-compromising behaviors, such as alcohol consumption and prescription drug use. Although survivors of sudden loss share many of the same general bereavement reactions as those of anticipated deaths, shock and denial are commonly associated with sudden death bereavement.

Grief following sudden loss is often intensified because there is little or no opportunity to prepare for the loss, resolve unfinished business, or say good-bye. The resultant grief reactions are intense and, in addition to shock and denial, the condition of yearning, separation pain, anger, guilt, sudden depression, despair, and hopelessness often result. Recent studies differentiate grief reactions across particular forms of sudden loss. Thus, while shock and denial are common among sudden death survivors, the results of comparative studies suggest that accidental death survivors report greater shock and denial than suicide survivors. Guilt, shame, anger, rejection, and the need to understand why are most characteristic of suicide survivors, whereas shock and disbelief, intense and prolonged sadness, guilt, rage, desire for revenge, fear, and self-blame are common reactions among homicide survivors.

Families may also experience multiple secondary losses, including the loss of income, the loss of home and business, and the loss of community status. When the body is not recovered, many legal and financial matters are left unresolved. Suicides, natural disasters, and mass shootings also may impact life insurance payments and create other legal liability issues.

The role that the loved one held within the family is gone, forever altering the relationships among the surviving family members. Family and marital relationships often become strained and disorganized and, in some cases, marriages end in separation or divorce. It is common for family members to believe that they are in a state of perpetual disarray with an enduring sense of unease and uncertainty about the future. It may take months and, in some cases, years for the family to reorganize and for relationships to heal.

The search for understanding and meaning of the loss also can challenge a survivor's religious or spiritual beliefs. The sudden death of a loved one can also provoke an existential or spiritual crisis that challenge one's faith or one's assumptions about life's meaning. Survivors may question their internal belief system and values. Goals, plans, and decisions that were important the week prior to the death abruptly seem trivial in comparison. Survivors are forced to re-evaluate life priorities that may lead to significant lifestyle changes.

Problems Unique to Sudden Death Survivors

Special problems arise if any of the grieving survivors were involved in or physically injured in an accident or disaster. Memories of the event tend to control the individual's thoughts. In some instances, the bereaved person may suffer from "survivor guilt," wondering why he or she survived the event when others died or believing that he or she could have or should have done more to prevent the tragedy.

Families experience difficulty in grieving and in reaching closure in those situations where no positive confirmation of the death occurs, when the physical body is not recovered, or when the family is unable to view the body. These circumstances make it difficult to grasp the reality of death as the bereaved continue to hope for the survival of their loved one. Only when the reality is fully understood can the bereaved move past the trauma to face the full realization and pain of the loss.

Reactions to sudden death can be further complicated if death is the result of a violent act, including suicide and homicide. One of the most agonizing kinds of death for family members to endure is suicide. Family members often blame themselves or are blamed for the death, resulting in feelings of shame, guilt, and anger. As a disenfranchised or publicly unacknowledged loss, suicide is often hidden so as to avoid the potential social stigma. The treatment homicide survivors receive as a result of the normal investigative process often leaves them aggrieved and alienated. During the initial questioning by police, it is not uncommon for homicide survivors to be considered early suspects in the murder of a loved one. Although survivors in these circumstances understand the importance of questioning family members as both witnesses and suspects, they nevertheless are frustrated with the process, and commonly perceive that valuable time is being lost in finding the real murderer. It is particularly difficult on the family if the killer of their loved one has not been caught.

The trial process is one of the most stressful experiences for homicide survivors, who often are surprised to find that neither they nor the victim are represented by the prosecutor or district attorney at trial. Further, homicide survivors are often unaware of the manner in which trials proceed, particularly in capital cases. Survivors learn that homicides do not always result in convictions and that sentences do not necessarily match the severity of the crime. Perceptions of injustice and a lack of respect for their loved one often cause further distress for the homicide survivor.

In public or particularly newsworthy events, such as natural disasters and mass shootings, survivors have to cope with the intrusion of the media. The media can become an additional source of distress—not respecting the family's privacy and replaying the tragic event on television. In the cases of suicide and murder, the media may even implicate family members as partly responsible for the deceased's actions or circumstances.

Contemporary Sudden Bereavement Research Issues

Important research findings indicate that sudden losses are distinct and, therefore, are likely to affect survivors in many different ways. Current research on grief and loss offers insight into the unique aspects of individual adaptation to coping with sudden loss, while also providing important clues or signs and symptoms of potentially serious complications that require prompt attention. An inability to function for weeks and even months after the death, abuse of alcohol and drugs, or symptoms of severe, major depression or post-traumatic stress disorder should all be addressed professionally and immediately, even if the person is grief stricken.

Although the available knowledge offers many important insights, the need exists for comparative studies that go beyond the prevalence of psychological distress across different bereavement groups; indeed, few studies have used nonbereaved control groups for enhancing understanding of the impact of sudden death on survivors. Such a limitation is

common, thus making it difficult to determine the relative severity of psychological distress among all family members. The use of retrospective data that are subject to the distortion of the facts, the forgetfulness of subjects, and the effect of recent stressors upon survivors also are known to affect how earlier experiences are remembered. Thus, longitudinal studies could provide some essential insights into how suddenly bereaved individuals who experience only transient reactions differ from those individuals who develop chronic abnormal symptoms.

Sudden Infant Death Syndrome (SIDS)

In sudden infant death syndrome (SIDS; sometimes called "crib death" or "cot death") an apparently healthy infant under one year of age dies suddenly with no advance warning. SIDS deaths are distinguished from other infant deaths by the fact that the death remains unexplained after a thorough case investigation, including performance of a complete autopsy, examination of the death scene, and review of the clinical history.

A diagnosis of SIDS is essentially a "diagnosis by exclusion," one made by ruling out all other possible causes and then recognizing some distinctive patterns. There are currently no definitive diagnostic indicators that unmistakably identify recognized abnormalities in an infant sufficient to cause a SIDS death. Nevertheless, there are some biological, clinical, and historical or circumstantial markers commonly found in this syndrome, including (a) tiny red or purple spots (minute hemorrhages or petechiae) on the surface of the infant's heart, in its lungs, and in its thymus; (b) an increased number of star-shaped cells in its brainstem (brainstem gliosis); (c) clinical suggestions of apnea or pauses in breathing and an inability to return to normal breathing patterns; and (d) a peak incidence at two to four months of age declining rapidly almost to nonoccurrence beyond one year of age.

Formal identification of SIDS as a syndrome—an identifiable constellation of events arising from an unknown cause—and its recognition by the World Health Organization as an official cause of death distinguish SIDS deaths from those caused by child abuse or neglect. This confirms that nothing could have been done ahead of time to prevent the death.

Incidence

During most of the 1980s and the early 1990s, SIDS accounted for the deaths of 5,000 to 5,500 infants each year in the United States. By 2004, however, the number of SIDS deaths had been reduced to 2,246. Nevertheless, SIDS remains the third leading cause of deaths in infancy (following congenital malformations and disorders related to short gestation and low birth weight). Approximately two-thirds of all infant deaths occur during the perinatal and neonatal periods (at the time of birth and during the first 28 days of life, respectively). Thereafter, SIDS is the leading cause of death in the United States among infants between 1 month and 1 year of age.

SIDS is a sudden and silent killer, often associated with sleep, but apparently involving no suffering. Characteristically, SIDS deaths show a pronounced peak in number during the colder fall and winter months of the year, especially during January through March in the United States or six months later in the southern hemisphere. Epidemiological studies suggest that SIDS may be associated with a detrimental prenatal environment, but infants at risk for SIDS cannot be distinguished from those at risk for many other health problems. In general, at-risk infants include those with low birth weight or low weight gain, as well as those whose mothers were less than 20 years of age, were anemic, had poor prenatal care, smoked cigarettes or used illegal drugs during pregnancy, or had a history of sexually transmitted disease or urinary tract infection. But none of these factors is sufficient to predict how, when, why, or if SIDS will occur.

SIDS appears in families from all social and economic groups, although African American infants are 2 to 3 times more likely to die of SIDS than Caucasian American babies. Approximately 60% of all SIDS deaths are those of male infants. The largest portion of SIDS deaths (approximately 70%) occurs in infants between 2 and 4 months of age, with most SIDS deaths (approximately 90%) taking place by 6 months of age.

SIDS-Related Research

Research on SIDS is extraordinarily difficult, facing problems that frustrate scientific investigators. For example, in SIDS there are no living patients to study because the first symptom is a dead baby. Also, risk factors for SIDS are not sufficiently strong or specific to permit identification of high-risk groups as subsets of the general infant population in which the natural history of a disease can be followed with smaller numbers of subjects. And there are no naturally occurring animal models for SIDS. As a result, SIDS is currently unpredictable and unpreventable, although it is possible to modify some risk factors for SIDS deaths.

Epidemiological and pathological research have dispelled numerous misleading and harmful myths about SIDS (for example, it is not contagious and does not run in families), while also ruling out many factors thought at various times to be causes of SIDS. For instance, SIDS is not the result of child abuse and it is not caused by vomiting and choking, minor illnesses such as colds or infections, or immunizations such as those involved in the DPT (diphtheria, pertussis, and tetanus) vaccines. Nor is SIDS the cause of every unexpected, sudden infant death.

Much attention has been given to the need for additional research on understanding the causal mechanisms behind SIDS. It is currently thought that brainstem abnormalities and neurochemical evidence might help to understand some infants' vulnerability to SIDS.

The "Back to Sleep Campaign"

In the early 1990s, research in Tasmania suggested that infants might be at less risk for SIDS if they were put down for sleep on their backs (supine) or sides, rather than on their stomachs (prone). That contradicted familiar advice favoring infants sleeping prone in order to reduce the risk of them regurgitating or spitting up fluids, aspirating them into their airway, and suffocating. The new research suggested that infants who sleep on their stomachs are at far greater risk of SIDS than they are of other problems.

In April 1992, the American Academy of Pediatrics (AAP) Task Force on Infant Sleep Position concluded that infants who sleep on their backs and sides are at the least risk for SIDS when all other circumstances are favorable (for example, when sleeping on a firm mattress without overheating, loose bed covers, or soft toys nearby). As a result, the AAP recommended healthy infants should be positioned on their sides or backs when being put down for sleep. Subsequently, the AAP revised its recommendation by emphasizing that positioning infants on their backs is the preferred position for their sleep at night and during naps, and by withdrawing approval for sleeping on an infant's side as an acceptable alternative.

In June 1994, a national "Back to Sleep Campaign" was initiated in the United States. This campaign, sponsored by the National Institute of Child Health and Human Development, is designed to employ literature, the media, and other avenues to raise professional and public awareness about the importance of sleep positioning as a way to reduce SIDS deaths. Dramatic and sustained reductions in SIDS deaths in the United States (over 45% from

1994 to 2004) and many other countries have been associated with initiatives like the "Back to Sleep Campaign" together with other proactive interventions, such as good prenatal care (proper nutrition, no smoking or drug or alcohol use by the mother, and frequent medical checkups beginning early in pregnancy) and maintaining a smoke-free environment after the baby is born, have had the effect of greatly lowering the risk that infants will die from SIDS.

Unfortunately, initiatives like these have not been applied equally in all racial and cultural groups in America. For example, less than optimal prenatal care is found in some sectors of our society. Moreover, African American mothers appear to be more likely than mothers in other racial and ethnic groups in our society to place their infants on their stomachs when put down to sleep. This reluctance to place infants on their backs for sleep appears to be directly correlated with less significant declines in SIDS death rates among African American infants than among infants in other groups in American society.

Bereavement After a SIDS Death

The unexpected death of an apparently healthy infant is most often perceived as a disruption of the natural order of things. A shocking event, it threatens the sense of safety and security in everyone it touches. These aftereffects are compounded by the suddenness of the tragedy, the lack of a discernible cause, and the involvement of the legal system.

Although no postdeath intervention can be expected to completely set aside the difficult challenges associated with a SIDS death, some interventions can help. For example, classification of the death as an instance of SIDS—naming it as an occurrence of a recognizable syndrome—may provide some partial framework for understanding. This diagnosis can help to diminish unrealistic guilt on the part of survivors, who might otherwise have thought they somehow contributed to the death or they could have done something to prevent it. Detailed information about the syndrome and extended support in bereavement can also help SIDS families. Contact with others who have experienced a similar death can be particularly useful.

Surviving children or subsequent siblings should be told in simple, concrete, age-appropriate terms that: the baby's body simply stopped working; the doctors and others who were involved do not know exactly why that occurred; and no one was able to make the baby's body work again. Grief reactions should be acknowledged and modeled, fears and guilt dispelled, and safety and love affirmed.

Helping After a SIDS Death

Many individuals are drawn into SIDS-related events, including first responders, other professionals, relatives, neighbors, and friends. Everyone should focus on listening and observing; offering understanding, practical assistance, and support; avoiding suggestions of blame; and being careful not to make family members feel guilty about the death of their baby. No one should accept at face value statements by distraught parents whose perceived guilt may lead them to unrealistic self-blame for what has happened. Different individuals from different religious or cultural backgrounds may respond in diverse ways to a SIDS death.

At the outset, it is important to assess the situation, initiate life support measures, obtain a history of the events that led to the call for help, and transport the infant to a hospital emergency department. Parents and other family members should be told what is being done and who will provide current and ongoing support. Whenever possible, at least one parent should be allowed to accompany the infant during transport; other transportation should be arranged for those who cannot come along in an ambulance. Arrangements need to be made to care for any involved children and brief explanations provided to them in an age-appropriate manner.

Once death has been pronounced, families will want to know the preliminary cause of death as soon as possible. In the meantime, parents and other family members need a quiet, private place in which to express their grief and be with loved ones. Some will want to help wash and clothe their infant's body. Many will desire to see, hold, or simply be with the infant, often in the company of siblings and other family members.

Helpers should handle the infant's body with sensitivity and respect, while facilitating leave-taking rituals and commemorative or legacy-building activities (e.g., cutting a lock of hair, taking pictures). Most families need information about SIDS, infant death, and loss and grief. Helpers can also

offer assistance in practical matters and arranging ongoing support. As soon as it is available after an autopsy and thorough investigation, families should receive the official postmortem report and have it explained to them.

Everyone who becomes involved in a SIDS death should acknowledge and honor their own reactions to this shocking event, appreciate individual coping strategies, be given access to resources for additional support, and be willing to draw on those resources as needed.

Suicide

Suicide is most succinctly defined as intentional, self-inflicted death. In addition to fatal behavioral outcomes, of course, a full consideration of suicide also includes those nonfatal, intentional self-harm situations traditionally referred to as suicide attempts, as well as a number of suicidal behaviors and related concepts. The word *suicide* derives from the Latin *suicidium,* a combination of the pronoun for "self" and the verb "to kill." It is suggested that this term was first used in 1651 (although an argument for 1642 has been advanced as well), with a number of phrases utilized throughout history to denote self-initiated deaths. Much discussion of the terms used with respect to suicide and its various dimensions exist. A number of efforts in recent years have taken place to derive a common nomenclature for suicide-related behaviors. It is believed that agreement on the terms used should aid communication about and understanding of the many related concepts. With the coining of the term *suicidology* in the 1960s by Edwin Shneidman for the scientific study of suicide and suicidal behavior, suicide experienced more widespread international attention in research and therapeutic intervention.

While the term *suicide* is of relatively recent origin, existing evidence suggests that suicide has occurred throughout history and across the world. It is clear that suicide has not been a behavior of one time period nor has it been a major characteristic of any one era or location. At least in Western Europe and North America, this long history of suicide and suicidal behavior has often been studied to provide perspective and insights into past and present attitudes, opinions, laws, and behaviors related to suicide. Historical events are noted, often beginning with ancient Greek and Roman philosophers who made arguments either defending (e.g., Seneca, Cicero) or condemning (e.g., Pythagoras, Aristotle, Plato) suicide. Traditional as well as more contemporary viewpoints of major religious beliefs can also be noted, with most groups (e.g., Christianity, Judaism, Islam) strongly opposing suicide, although others are more ambivalent or mixed in their teachings (e.g., Buddhism, Hinduism). In Western Europe and the United States in particular, the main rulings, synods, and councils of the Roman Catholic Church over the centuries established clear and increasing condemnation and sanctions against suicide, most often as a sin. These sanctions included altered or refused burial rights and excommunication. Such religious

backgrounds and the influence of religion on governments produced laws. For example, suicide was a felony in mid-14th century England, resulting in the forfeiture of all land and goods. Suicide remained a crime in British law until 1961.

The superstitions and practices associated with suicide during these periods of time included treatment of the deceased, such as being buried outside sacred ground or even burial at a crossroads at night with a stake driven through the heart. In some cases, bodies were drug through the streets by horses, hung on public display, or thrown in the sewer or a town dump. With the passage of time and different attitudes, particularly the publication of medical considerations of suicide in the mid-1800s, the behaviors shifted away from primarily sin and criminal acts. Instead, suicide became an "insane" behavior. In turn, this interpretation, with its implications of physical and perhaps personality weaknesses or unsound minds, produced feelings of shame and disgrace. Ultimately, with the end of the 19th century and the different thoughts about suicide that emerged in the first half of the 20th century, those who died by suicide or were suicidal were often considered mentally ill. Though much of the shame and stigma remained, religious and social interpretations often held the person less responsible for their actions and many sanctions were relaxed.

The 1897 publication of Émile Durkheim's *Le Suicide* set the stage for the historical events of the 20th century. While not the first book to provide a theoretical interpretation of suicide, it is usually considered, with its statistical methodologies, to be the beginning of what Shneidman would call "suicidology." This theory was followed by others, including the psychoanalytic ideas of Sigmund Freud that contrasted sharply with Durkheim's social forces explanations.

Along with the founding of psychology as a field and its attention to mental disorders and their treatment, the emergence of scientific investigations and the development of psychological therapies for both suicide and depression affected not only the ways in which suicidal behavior was understood, but also the manner in which individuals who were suicidal were treated. Among the most prominent of these treatment-related movements was the founding of suicide prevention and crisis intervention services in both the United States and Europe. These services often took the form of telephone hot lines, typically available 24 hours a day to those who were in suicidal crisis. Eventually, many of these crisis centers and suicide prevention centers offered other services, such as therapy and eventually support groups for those who lost their loved ones to death by suicide.

More recent emphases on physiological explanations of suicide have led to additional interventions, often in the form of widespread use of antidepressants. By the end of the 20th century and the beginning of the 21st century, suicide is most often viewed as a mental health problem, similar to many physical health problems, with lessened condemnation and stigma.

Also advancing the study and treatment of suicidal individuals was the founding of professional organizations that have produced evidence and focus on suicidal behavior over the years. Perhaps most prominent among these were the International Association for Suicide Prevention (founded in 1960), the American Association of Suicidology (1968), the American Foundation for Suicide Prevention (1987), and a community action and advocacy group, Suicide Prevention Action Network USA (1996).

Other historical events that have contributed to these changing attitudes and beliefs, in the United States at least, have been the perspective of suicide as a public health problem. This shift came about primarily by the publication of the Surgeon General's *Call to Action to Prevent Suicide* in 1999 and the subsequent appearance of the *National Strategy for Suicide Prevention* in 2001. This latter document contained many goals and objectives in the national fight to prevent suicide (several countries have adopted similar national strategies). At this time, most states have created state coalitions and groups that have adapted these goals and strategies to their own state efforts. In addition, legislation in recent years has provided federal funds for suicide research and prevention activities, both generally as well as specifically targeted to groups such as the young, the elderly, Native Americans, college students, and veterans.

A long-standing tradition in the study of suicide is the utilization of statistical data derived especially from official national mortality figures. Durkheim established the use of such data to test his theoretical ideas about social factors in suicide.

Individual nations and the World Health Organization regularly compile and disseminate mortality figures and often reports that specifically highlight trends, patterns, and groups at high risk for death by suicide. While the reliability and validity of official data have been questioned in several ways, the figures might be interpreted as imperfect indications of the actual levels of suicide, but at the same time they are likely to represent a conservative estimation. That is, it is likely that no fewer suicides than those officially recorded in death records occur, though there may well be more actual suicides than are officially counted due to such factors as shame, stigma, insurance regulations, and social attitudes. Keeping this perhaps conservative nature of suicide statistics in mind, some idea about the degree to which suicide is an important mental and public health issue can be determined.

Worldwide Incidence of Suicide

Epidemiological data compiled by the World Health Organization suggest that over 1 million suicides take place each year worldwide. Although there are few official data regarding nonfatal suicide attempts, one common estimate is that there are perhaps 25 nonfatal attempts for each death. If this applies worldwide, a figure of 25 million attempts annually would result. For a more complete idea of the full toll of suicide and the lives affected, the number of those bereaved by suicide (see the entry for Suicide Survivors) would also need to be included. Crude estimates place the number of bereaved individuals at no less than six per death by suicide. As the combination of these figures shows, suicide affects large numbers of people annually around the world.

Although suicide exacts a large toll each year, there is tremendous variability across nations in the level of suicide observed. Among the consistent findings in these international figures, it is observed with few exceptions that men are generally several times more likely to kill themselves than are women. Many other demographic variables have been investigated as well. For instance, the world's nations display several patterns of suicide by age, with peak life periods for suicide occurring at young ages in some nations and in late life in others. In addition, seasonal (risk often higher in warmer/spring or summer months), day of week (Mondays usually highest), race and ethnicity (varies by nations), method employed (varies widely worldwide), and geographic regions of nations have also been reported. As an example, in the United States, the highest risk for suicide is observed among Caucasians, the elderly, and men, and are markedly higher in the states of the Rocky Mountain and Southwest region, and more than half the cases use firearms. In the United States as well as some other nations, recent trends in rates (that take into account the number of individuals in the population) have shown decreases for nearly all groups through the 1990s and the mid-2000s.

The previously noted data represent some of the high-risk demographic groups for suicide deaths. There are, as noted, far more nonfatal attempts. In addition, in the case of self-harming, nonfatal behaviors, the groups most often found to be at highest risk differ from those who die as a result of their actions. Studies of nonfatal attempts (referred to also as deliberate self-harm or parasuicides) have demonstrated highest risk among the young and women.

The use of official statistics provides one dimension of high risk for suicide. However, these groups are not the only, or even necessarily the most predictive, with respect to elevated risk. For instance, the strongest relationships between suicide and suicidal behaviors have been observed for psychopathology. Some studies have suggested that as many as 90% of all suicides had some form of mental health condition. Nearly all psychopathologies have been shown to elevate suicide risk, but this is particularly true for mood disorders (especially depression), with substantial but lower risk compared to depression for alcoholism/substance abuse, and schizophrenia. Comorbid conditions are also often noted (e.g., mood disorder and substance abuse). Other high risk factors include past suicide attempts as well as psychosocial factors, such as bereavement, life changes (e.g., job loss or economic difficulties, divorce or separation), family history of suicide and/or psychopathology, and physical illness (especially for the elderly). It is important in the case of all risk factors to realize that the presence of these factors, even several simultaneously, does not ensure that suicidal behavior will occur. Individuals have many forces working to protect them or lessen their likelihood

of suicide or suicidal behaviors, including among them social supports, personality and past behavior, and coping mechanisms. Suicide is not only a complex behavior to predict for individuals, but also demonstrates the multiple factors involved in human behavior.

Theoretical Explanations of Suicide

The multifactorial nature of suicide regarding prediction is mirrored in the theoretical and other explanations of suicide that have been advanced over time. A wide range of forces have been central to the many theories that have emerged, including social, psychological, and biological/medical. At the same time, however, these various explanations of suicide have most often focused on a single domain or issue, seemingly ignoring the obvious multiplicity of factors observed in individual cases of suicide. This resulting focus on single factors or issues has produced relatively distinct theoretical explanations of suicide, but has not, in isolation, increased the ability to predict, effectively treat, or prevent suicidal behavior. The need for integrated theory to explain suicide is apparent but has thus far not been advanced.

In the absence of integrated models, theories suggesting individual issues in the etiology of suicide have influenced therapies and interventions as well as the way in which motivations for suicide have been explained generally. One of the earliest modern theories was Durkheim's sociological theory of suicide. Durkheim advanced four types of suicides that are produced by the social forces of integration (involvement with individuals and social groups) and regulation (influence over the individual by such societal aspects as laws or customs). More than a century later, his concepts of anomic, egoistic, altruistic, and fatalistic suicide continue to influence research and social explanations of suicide. Subsequently, other sociologists have most often tweaked aspects of Durkheim's theory, though some have utilized multivariate statistical methods that include a broader range of social forces.

Early in the 1900s, the first psychological theories of suicide were advanced. Among them were Sigmund Freud's psychoanalytic explanations that centered particularly on the role of depression in suicide, as well as the idea that suicide is the manifestation of aggression and anger toward a loved one that is instead turned inwardly toward the self. Freud also more generally discussed suicide resulting from basic human life and death instincts when death forces overcome those for life. Later, psychological ideas stressed mechanisms such as the personality and traits of the individual, but the most influential psychological theories focused on cognitive and/or learning-related issues. Prominent among these notions have been the importance of helplessness (including learned helplessness), where the individual feels that they are personally unable to effect changes that could alter their lives, and hopelessness, where the individual believes there are no solutions to their problems. These two cognitive sets have often been found in studies of suicidal individuals.

Finally, one of the most influential theoretical efforts to help understand why individuals kill themselves was advanced by Edwin Shneidman. In his most complete model, Shneidman posits 10 commonalities that he observed in the suicidal patients he had treated. While these characteristics included hopelessness-helplessness, frustrated psychological needs, and others, in years following this model Shneidman ultimately argued that "suicide is caused by psychache." Psychache, one of the 10 commonalities, referred to the individual's perception that the psychological pain they were experiencing had reached an intolerable level. This explanation implied a clear clinical prescription for the therapist: to prevent suicide and reduce the individual's pain.

The third basic category of suicide theories involves biological factors. Even relatively early in the history of suicidology, studies of family trees had observed that suicide (like depression) appeared to "run in families." This observation raised the distinct possibility that suicide might be produced by genetic transmission or predispositions. While these studies could not rule out the possible alternative explanations that those who are related biologically often live in the same environments with the same stressors that could increase suicide risk, or that the person who died by suicide might serve as a model for other family members and their subsequent behaviors, the evidence made biology a potential aspect of suicidal acts. Far more widespread than genetic explanations was later research evidence regarding the role of

biochemistry and, more specifically, neurotransmitters associated with depression. The strong relationship of depression to suicide provides an indirect route to suicide through depression.

Intervention With Suicidal Individuals

Individuals who are suicidal have received treatments largely consistent with the theories that have been advanced. In the case of psychological explanations, various forms of psychotherapy (including individual, group, and family) have been utilized widely. Most often in recent years, cognitive and cognitive-behavioral approaches have been employed to confront and eliminate the several potential cognitions and behaviors of the suicidal individual that lead them to suicidal ideation and acts. One particularly effective treatment is Dialectical Behavioral Therapy, developed by Marsha Linehan. This therapy focuses on psychosocial forces in suicide, specifically targeting not only suicidal and injurious behavior but also behaviors that interfere with treatment and the individual's life. In addition to these largely psychological therapeutic approaches, biological and especially biochemical factors in suicide and depression have led to widespread prescription and use of antidepressant medications (not without controversy, however, including evidence that some antidepressants may actually increase suicide risk in some patients or categories of patients). Recent evidence has found that the most effective treatment of depression (with the associated lessening of suicidal behavior) is observed when there is a combination of psychotherapy and antidepressant medications rather than either one alone.

Therapeutic intervention is not the only avenue for suicide prevention. At least since the 1960s, suicidologists have attempted to educate individuals, from gatekeepers who frequently come into contact with the suicidal to the general public, about how to recognize those who are suicidal and how to get help for them. This public education has centered on the delineation of clues or warning signs that are exhibited by those contemplating suicide, as well as the circumstances and factors associated with high suicide risk. In all cases, however, one of the basic measures to take if warning signs are observed is to seek professional help immediately. In addition to mental health professionals in the community, another source of assistance available in a large number of communities is found in crisis intervention or suicide prevention centers noted earlier. The public health approach to suicide stresses prevention measures at several levels, with such efforts as teaching coping mechanisms at young ages to method restriction measures.

Finally, ethical discussions of suicide are not new. Philosophers and others have advanced ideas about the right to and the morality of suicide throughout time, as well as the ability to make a rational decision to die. In the late 20th century and the start of the 21st century, these discussions have emerged as more than academic exercises. Legislation regulating, and in some cases providing for suicide, have resulted from and have produced subsequent social and cultural battles. At a point in time when suicide prevention and treatment efforts are at their most widespread, the arguments defending and making suicide available as an option have taken place on several fronts. Books were published in several nations that provided specific information about how to kill oneself. A physician, Jack Kevorkian, assisted over 100 individuals before being convicted for his assistance to an individual he helped die. Laws and their enforcement have led to the availability of assisted suicide in some nations, such as the Netherlands, and Oregon in the United States, and permit assisted suicide under certain conditions. Self-inflicted intentional deaths continue to be viewed by some as an option to hasten death, while in the larger community, and especially in the mental health arena, the prevalent viewpoint seems to be that death by suicide is unnecessary, and it can be and most often should be prevented.

Suicide, Counseling and Prevention

The term *suicide* encompasses both behaviors in which people intentionally cause their own deaths (complete suicide or fatal suicide) and those behaviors where the person survives the action (attempted suicide, parasuicide, or deliberate self-harm). Suicidal behavior, more than many other behaviors, often creates severe anxiety in those professionals who encounter and endeavor to help such individuals because of the fear that the smallest misstep may result in their clients' deaths.

Overview

There are six major tactics that have been employed for preventing suicide:

1. *Preventing access to lethal methods of suicide*. Preventing access to lethal methods of suicide includes such tactics as fencing in high bridges and buildings to prevent people jumping from them, passing and enforcing stricter gun control laws, and using less toxic and lethal medications for psychiatrically disturbed individuals. It is impossible, of course, to limit access to all methods for suicide. For example, drowning, hanging, and cutting are available to most individuals. Furthermore, it is likely than many, although not all, individuals will switch methods for suicide if their preferred method is unavailable. However, this tactic may delay the suicidal action and provide an opportunity for crisis intervention.

2. *Educating people about suicide and the resources available for suicidal individuals*. These programs have been primarily set up in schools where the students are given information about suicide and the community resources available, and sometimes, basic information about crisis intervention. There is research that indicates that these programs do inform students about suicide and resources, but there is no evidence yet on whether they indeed prevent suicide.

3. *Educating general practitioners*. In some regions of England, Hungary, and Sweden, educational programs have been established to educate general practitioners and family doctors on the identification of and appropriate medications for the depressed patients that they encounter in the course of their practice. The available evidence to date indicates that these programs may, in some cases, result in a temporary reduction in the incidence of suicide in some segments of the population (for example, women).

4. *Crisis intervention hot lines and walk-in clinics*. Telephone crisis intervention centers have been set up in many nations of the world, some of which have walk-in clinics with around-the-clock access so that suicidal individuals can receive crisis intervention. Some nations have now established toll-free numbers that serve the whole nation, and crisis intervention is now available online via e-mail and instant messaging.

5. *Programs for survivors*. Survivors are those who have had a loved one or significant other commit suicide. Research has shown that this type of loss increases the potential for suicide in the survivors, and self-help groups are available in many nations for survivors (see the websites mentioned earlier). Protocols have also been established for helping people after friends, peers, or fellow staff members have committed suicide.

6. *Providing treatment for suicidal individuals*. Once suicidal individuals have been identified or

have sought help on their own initiative, they can be provided with effective treatment involving both medication and psychotherapy. These are addressed in the following sections.

Medication for Suicidal Individuals

The primary tactic for helping suicidal individuals is to identify their psychiatric disorder and prescribe the appropriate medication. If the suicidal individual has schizophrenia, then an anti-psychotic medication is needed; if they are anxious, an anxiolytic agent is needed; and if they are depressed, either an antidepressant or a mood stabilizer (for bipolar affective disorders) is needed. There is a great deal of research on the effectiveness of these medications, with clear evidence-based data.

For example, there is good evidence that clozapine reduces subsequent suicidal behavior in schizophrenic patients, although it may increase mortality from cardiovascular side effects. Most suicidal individuals are depressed, and the majority of these are diagnosable as depressive disorder for which antidepressants are useful. In recent years, countries such as Hungary and Sweden have witnessed a tremendous increase in the recognition and medication of depressed individuals, and this has been accompanied by a decline in the suicide rates of these nations. However, not all nations have witnessed this decline in suicide rates as antidepressants became more widely used. Furthermore, there have been claims that the use of selective serotonin reuptake inhibitors (SSRIs) for depression does, in rare cases, increase the potential for suicide. This has led to warnings to physicians that the SSRIs are not suitable for children and adolescents without very careful monitoring. However, the mortality rate (from accidental overdoses and suicide) is much less for the SSRIs than for the older antidepressants. A recent analysis of data from 26 countries for up to 25 years estimated that an increase in SSRI sales of one pill per capita (a 12% increase over 2000 sales levels) would result in a 5% decline in deaths from suicide.

Lithium maintenance therapy has long been used to treat patients with bipolar disorders (commonly known as manic-depressive disorder), and there is good evidence to show that it reduces the risk of suicide in these patients. In addition, recent research indicates that lithium may be useful in reducing suicide behavior for patients with any type of affective disorder.

Psychotherapy

While the typical treatment that suicidal individuals receive (for example, after emergency room visits) does not seem to have proven effective in preventing later suicidal behavior, there is some evidence that focused counseling may be beneficial. Although all of the major systems of psychotherapy have been applied to suicidal clients, two systems are especially useful—crisis intervention and cognitive therapy.

Crisis Intervention

Crisis intervention was first applied to counseling suicidal clients when telephone hot lines were established in the 1960s. Most communities in the developed world have access to a local or national telephone service that provides crisis counseling for suicidal individuals. The crisis counselors are typically volunteer paraprofessionals who have been trained in crisis intervention.

The first step is "active listening," the popular term for the person-centered counseling developed by Carl Rogers. The next step is the assessment of the person's resources, both personal strengths and social supports. Finally, the counselor helps the client devise one plan of action, even if it is a small step, and the client is encouraged to carry out this plan and to call back to let the center know whether the plan helped the client. Now that crisis intervention for suicidal clients has moved to the Internet, the first step in crisis counseling has required modification because e-mailing requires more substantial responses on the part of the crisis counselor than person-centered therapy typically entails.

There has been some research on the usefulness of specific types of responding by crisis counselors for positive short-term outcomes and documentation that suicide prevention centers may have a weak, although statistically significant, impact on the societal suicide rate. But the overall usefulness of crisis counseling for preventing suicidal behavior does not yet meet the criteria for evidence-based treatment.

Cognitive Therapy

The use of cognitive therapy for suicidal clients was stimulated by the research in the 1960s documenting dichotomous and rigid thinking in suicidal individuals. Because cognitive therapy is a short-term psychotherapy focused on changing the irrational thinking of clients, and because suicidal individuals usually show irrational thinking, cognitive therapy is useful for dealing with suicidal clients. Building on the rational-emotive therapy, cognitive-behavioral therapy was first successfully applied to depressed and anxious clients. Since that initial success, the cognitive-behavioral therapy and other variants of cognitive therapy have also been used successfully with suicidal clients.

Dialectical behavior therapy (DBT) was developed to treat borderline personality disorder, but DBT has also been successfully used with suicidal clients. DBT is a cognitive behavior therapy with additional components, and the manuals and books describing DBT present a complete systematic guide for conducting psychotherapy, with a special focus on the problems presented by clients with borderline personality disorder. In addition to a cognitive-behavioral approach, DBT focuses on the dialectic involved (accepting and validating clients' behavior while insisting that they change) and on some Zen Buddhist meditation techniques (to encourage mindfulness), which help clients learn to observe and describe, be nonjudgmental, and focus on the present. DBT takes a minimum of a year, and employs two counselors holding separate sessions with each client.

Other Systems

Several other systems have also explored their use for suicidal clients. Voice therapy, a system of counseling that addresses the early trauma that characterize the lives of suicidal clients, and the defenses that suicidal individuals develop, in particular the voice process, a well-integrated, discrete antiself system that appears as intrusive self-deprecating thoughts in the individual's mind. The psychotherapist helps the individual to recognize and express this voice so that the psychotherapist can assist the client in challenging it.

Mental health professionals do not always agree that suicide is always an inappropriate choice. Under certain circumstances, such as extreme physical or psychological pain, suicide may be viewed as a rational and appropriate decision. There are websites that provide information on how to choose an appropriate method for committing suicide, and there are books helping people make a good decision about this option. Finally, some countries, such as the Netherlands, and some states, such as Oregon in the United States, also have established procedures to follow for those who want assistance in committing suicide.

Suicide, Cross-Cultural Perspectives

An estimated 850,000 to 1 million people worldwide died by their own hand during the year 2000. Although a worldwide average rate of suicide is not available because of the unevenness of reporting, the World Health Organization offers that for every act of successful suicide there are approximately 10 to 20 unsuccessful attempts. In terms of the human condition, for every suicide there are surviving family members and significant others whose lives are profoundly affected

emotionally, economically, and socially. These issues are addressed herein.

Worldwide data that are available indicate suicide ranks as the 13th leading cause of death and is generally ranked in the top 10 leading causes of death in the more developed nations. Indeed, in the developing countries of the world, suicide has increased more than 60% since 1960. This problem is particularly acute for India and China, which currently record the highest rates of suicide, 98 and 99 per 100,000 people, respectively. Along with Japan, India and China are thought to account for up to 40% of the total number of suicides recorded each year.

Among the young, ages 15 to 44, suicide ranks as the 4th leading cause of death worldwide. Unlike other leading causes of death, including heart disease and cancer, suicides are preventable. Suicide victims die at an earlier age than cancer or heart disease decadents; the modal age for suicide in the United States is currently a 44-year-old male with no life-threatening diseases. Hence, the years of potential life lost in the case of suicide deaths is much greater per death than for the most common causes of death.

The suicide rates (per 100,000 population) of the world's nations show considerable variation. In the year 2000, for example, suicide rates were as low as 5.5 per 100,000 for males in Greece and included rates many times greater such as 50.7 per 100,000 in Hungary. For females during that same year, the rate of suicide ranged from 1.5 per 100,000 in Costa Rica and Greece to a high of 15.1 per 100,000 in Hungary. The highest rates are generally found in Eastern Europe and the lowest rates in Latin America and Muslim nations. Suicide rates also tend to increase with age, and are higher among men than women. Given the statistics noted previously, this entry is organized around five features of society that increase the risk of suicide. These risk factors include gender, modernization, marital disruption, economic strain, and the "culture of suicide."

Gender Roles and Gender Role Change

One of the most well-documented social facts in comparative suicide studies is that men have a higher suicide rate than women. In the developed nations, for example, the male suicide rate is generally at least twice that of females. In the United States, the ratio is currently 4.3, in Austria 2.8, France 2.9, and Sweden 2.5. Reasons for this gender differential are not fully understood. Common explanations include (a) religiosity levels, a protective factor against suicide, are higher among women than men; (b) a key risk factor for suicide, alcoholism, is five times higher among men than women; (c) greater help-seeking behavior for mental health problems among females than males, both for professional help as well as help from support networks; (d) women have stronger negative attitudes toward suicide than do men; and (e) women have less access to and less knowledge about firearms, a highly lethal means of suicide, than do men.

However, the ratio in male to female suicide rates has changed over time. For a sample of more developed nations, during the period 1919 to 1972, as levels of economic development increased, there was a decline in the male to female ratio in 16 of 17 countries. This was a period marked by substantial increases in women's labor force participation rates. Further, women often faced a "double shift of work" characterized by paid work in the labor force during the day and long hours of housework and child care during the evening and weekends. Conflict between the script roles of paid work careers, motherhood, and homemaker were thought to contribute to an increasing suicide risk for women.

However, in most developed nations the convergence in gender suicide rates reversed in the 1970s. Female rates started to go down and/or male rates increased faster than female rates. In the United States, for example, the ratio converged to 2.6 by 1970, but diverged to 4.3 by the year 2000. This was mainly due to a fall in the female suicide rate from 6.3 to 4.3 per 100,000.

During this same time period, a critical mass of women entered the labor force and cultural definitions of female and male roles changed. Defining the working mother in more positive terms, new social arrangements emerged intended to address the dual roles of work and home, including widespread use of day care centers and greater male participation in household work and child rearing. And as women achieved substantial gains in the labor force, male dominance of the more prominent occupational positions declined. But instead of declining, male suicide rates increased.

A similar analysis focusing on 18 developed nations reported male and female suicide trends during the years 1953 to 1992 lent similar support for a curvilinear argument. A period of convergence in the gender ratio in suicide was followed by a period of divergence beginning in the 1970s, with male rates increasing disproportionately to female rates. Institutional adjustments to gender role change in late modernization protect women from suicide more than men. In Australia, another highly developed nation, the gender suicide ratio diverged from 2.2 to 3.8 between 1970 and 2000. As shown in Table 1, male rates increased while female rates decreased over this 30-year period.

Suicide and the Modernization Process

A leading predictor of the wide variation in suicide rates among nations is the level of modernization. Modernization comprises three interrelated dimensions: economic development, urbanization, and secularization. Each tends to break down the ties between the individual and society. Migration from the countryside to urban centers erodes ties to ancestral farmland, friends, and kin. Industrialization, driven by specialization or occupational differentiation and efficiency, requires mass education. Education, however, contributes to critical thinking, questioning, and a weakening of religious faith. Industrialization thrives on a large mass of consumers. Religiosity is weakened, while a value of consumer items and materialism are strengthened. In traditional agricultural culture, where most people had the same occupation of farmer, dogmatically shared the same unquestioned religious beliefs, and had ties to ancestral small villages, this was replaced by an ever-changing, questioned, and diverse culture and social order wrought by industrialization.

In addition, a culture of tolerance is fostered by the financial security of industrialization. Widespread poverty, famine, drought, epidemics, and other calamities are eliminated or brought under control by modern medicine and technology. In analyses of people in over 80 nations, it has been determined that financially secure populations in the more developed nations are more apt to be tolerant of other ethnic groups, political opponents, religious differences, and a host of formerly forbidden deviant behaviors, including divorce, homosexuality, and suicide.

The most widely studied aspect of modernization in suicide studies is level of economic development. The notion that the greater the economic development, the greater the suicide rate has been supported by a large number of cross-sectional comparative studies. However, choosing suicide over life is thought to stabilize or even decline at advanced levels of modernization. After the initial shock of rural to urban migration, and people adjust to living in a largely secular social order, suicide rates may decline. An analysis of Finland during the years 1749 to 1900 (the oldest set of suicide data) found that a 1% increase in urbanization was associated with a .22 increase in suicide rates from 1749 to 1900. However, from 1900 to 1985, a 1% rise in urbanization was associated with just a .12% rise in suicide rates. Further, as the data in Table 1 suggest, Finland's male suicide rate stabilized at 34 per 100,000 people between 1970 and 2000. But many nations are currently in the process of modernization, and their suicide rates would be expected to increase. For example, in Table 1, suicide rates increased between 1970 and 2000 in many developing nations, including Costa Rica (4.1 to 10.7 per 10,000), Mexico (1.8 to 6.0), Panama (5.3 to 8.4), and Thailand (5.0 to 13.5).

Some variation in the modern suicide rates is mediated by culture zones. One assessment of annual suicide trends in 20 advanced European nations from 1900 to 1972 found that no clear relationship existed between modernization data and annual suicide rates. Suicide rates increased in one-third of developed nations, decreased in one-third, and remained relatively constant in a third. Predominantly Catholic nations, a culture zone incompatible with modernization, tended to fall into the first group. Protestant nations, with values more compatible with industrialization, comprised the second group. Nations with a mixed religious system constituted the third group.

More recent suicide rate trends in developed nations tend to confirm this pattern. The male suicide rate in Catholic Ireland increased from 3.0 to 20.3, the male rate in Protestant Sweden decreased from 31.3 to 18.3, and the male rate in religiously mixed Switzerland stayed essentially the same (27.4 to 27.8) during the 1970 to 2000 period.

Marital Disruption

Supportive family structures protect against suicide. Conversely, as families are disrupted by divorce and widowhood, suicide risk increases. Loss of a spouse is often marked by social isolation, depression, and economic hardships, all of which contribute to suicide. In the United States, divorced people have a depression level that is 40% higher than their married counterparts. A review of 132 studies containing 789 findings from 1880 to 1995 determined that divorce and divorce rates tend to be predictive of suicide risk.

Divorced people are typically at greater risk of suicide than married people. In a review of a century of research, a total of 426 of 493 findings (86.4%) determined that divorced people had higher suicide rates than married people. In Austria, divorced people have a suicide rate of 128.6, compared to 30.5 per 100,000 for their married counterparts. A coefficient of aggravation (COA) divides the suicide rate of the divorced by that of the married. The COAs for divorced men versus married men were 4.42 in Australia, 6.18 in Denmark, 4.24 in Finland, 2.21 in France, 5.08 in West Germany, 3.57 in Italy, 5.09 in the Netherlands, 3.59 in Norway, 3.79 in Sweden, 4.54 in Switzerland, 3.72 in the United Kingdom, England, and Wales, and 4.17 in the United States. For females, the COAs were 4.05 in Australia, 4.55 in Denmark, 2.94 in Finland, 1.93 in France, 3.08 in West Germany, 17.0 in Italy, 3.56 in the Netherlands, 2.86 in Norway, 3.35 in Sweden, 3.4 in Switzerland, 2.61 in the United Kingdom, England, and Wales, and 3.22 in the United States. With the exception of Italy, divorce is a stronger risk factor for suicide in the case of males than for females. Nevertheless, divorce substantially raises the risk of suicide for women as well as men in all nations for which data are available. In most nations, divorced people have a suicide rate three to four times greater than married people of the same age.

Economic Strain

The rate of suicide among the unemployed varies across nations. This fact corresponds to the size and duration of the economic safety net for the unemployed that vary from nation to nation to include unemployment programs and the size of and duration of unemployment benefits. There is substantial evidence that the unemployed have a higher suicide rate than their counterparts, including age-matched working peers. Recent research in England determined that the unemployed had a suicide rate of 20.5 per 100,000, compared to 10.3 for the general population. In Austria, the relevant rates were 93.3 versus 25.0 per 100,000; and in Italy, 3.2 versus 2.1 per 100,000. And a study of 9,011 suicides and 180,220 living controls in Denmark determined that unemployment raised the odds of suicide between 1.69 and 2.38 times. A New Zealand study determined that unemployed males were 2.7 times more apt to die by suicide than employed men. Unemployed females were 2.86 times more likely to commit suicide than their age matched peers. In the United States, a longitudinal study determined that unemployed males were 2.3 times more apt to die by suicide than employed men. And in investigations that control for psychiatric morbidity, such as depression level, unemployed males were found to be at greater risk of suicide than employed males.

Socioeconomic Status (SES)

Specialized high status groups, such as physicians, have high suicide rates. However, in general the results have been highly consistent: the greater the socioeconomic status (SES) of groups, the lower their suicide rates. That lower status groups should have higher suicide rates would be expected because they tend to have higher risk factor rates, including unemployment, divorce and desertion, morbidity, severe mental disorders, and crime victimization.

A variety of measures of socioeconomic status are used to assess the relationship between SES and suicide risk. In a New Zealand cohort study, men with household incomes of less than $20,000 were 2.22 times more apt to die as a result of suicide than men with household incomes of greater than $50,000. For women, the corresponding risk ratio was 2.0 times as great as that of males. Recent English data, for example, shows a rate of 46 per 100,000 for unskilled workers, more than 3 times the rate for professional workers (13 per 100,000). In Australia, the suicide rate for all manual workers (skilled and unskilled combined) was 32.5 per 100,000, compared with a suicide rate of 20.5 per 100,000 for professional and managerial workers

combined. U.S. laborers have a suicide rate of 94 per 100,000, more than 8 times the national average. One U.S. study employed a composite index of income, occupation, and other dimensions of status to divide the population into four socioeconomic status groups. Males in the bottom quarter in SES had a suicide rate of 42.2 compared to 18.6 per 100,000 for men in the top quarter. For females these rates were 7.2 versus 5.8 per 100,000.

The Culture of Suicide

The most recent development in comparative analysis of national suicide rates involves the influence of public opinion or the degree of approval of suicide. Research samples of 19 to 35 nations links the degree of public approval of suicide to national suicide rates; that is, the greater the public approval of suicide, the higher the suicide rate. American research has often linked the degree of suicide acceptability in individuals to their relative risks of suicide attempts and suicide completions. Public approval of suicide in the case of a terminal illness, bankruptcy, being tired of living, and dishonor of family are also measured in world values surveys. In addition, the U.S. general social surveys conducted during 1972 to 2006 measure suicide acceptability. The results tend to demonstrate a positive relationship between high cultural approval of suicide and high suicide rates.

In Table 2, the data refer to the question "Is suicide when one is incurably sick never justified, always justified, or somewhere in between?" On a scale from 1 to 10, the average acceptability score for these worldwide data is 4.11. Suicide approval scores ranged from a low of 2.39 in Poland and 2.57 in Catholic Ireland, to 6.82 in China and 6.14 in Finland. This measure is also reported to be highly correlated with other measures of suicide acceptability in the world values survey.

In sum, there are many risk and protective factors for suicide. The risks include psychiatric factors, such as depression, manic depression, and schizophrenia; the availability of firearms; exposure to mass media stories and films concerning suicide; and biological factors, such as low serotonin. Protective factors are better known as the factors that constitute the strength of the social bond first discussed by Émile Durkheim. Although the risk factors have not been subject to rigorous comparative research, this void represents a fertile opportunity for future cross-national investigation.

Suicide Survivors

Survivor of suicide does not refer to individuals who have made a nonfatal attempt on their life. Rather, a survivor of suicide is a loved one or other individual who has experienced the death by suicide of someone close to them. The less ambiguous wording "bereaved of suicide" is used in Australia. The term *survivor of suicide*, therefore, is appropriate in the context of the aftermath of a suicide death. The sequelae of suicide may include a difficult and complicated bereavement experience. Edwin Shneidman, founder of the American Association of Suicidology, expressed his belief that the greatest mental health toll associated with suicide occurs among the survivors of suicide. Despite this contention, the topic of suicide survivors remains one of the most neglected areas in suicidology.

Although relatively little research exists regarding suicide survivorship, available evidence provides initial insights of suicide survivorship. Virtually no epidemiological data have been gathered regarding how many individuals are survivors or their characteristics. It is usually suggested (though not based on epidemiological investigation) that there are at least six survivors for every suicide. If true, the 32,000-plus annual U.S. suicides produce more than 190,000 survivors each year. As one measure of the cumulative effect, the more than 750,000 suicides in the last 25 years would be associated with over 4.5 million survivors, or at least 1 of every 65 Americans (1.5%). One small-scale study implied 5.5% were survivors. Even using conservative estimates, the number of surviving family members and friends is substantial.

The impact of suicide on survivors' grief and bereavement has yet to be adequately studied. Personal accounts and research have provided delineation of some characteristic aspects of suicide bereavement. While potentially unique features may result from experiencing the suicide of a loved one, it is important before considering these to understand that suicide survivors share aspects of grief common to essentially all bereaved individuals. For instance, as with other deaths, the suicide grief process is unique and individual, it follows no time frame or specific duration, and its movement is not always in a forward direction.

Many specific characteristics of grief following death by suicide have been described in the past 35 years. University of Michigan professor Albert Cain produced one of the earliest considerations of the topic in the 1972 edited book, *Survivors of*

Suicide. Cain's book provided a portrayal of the reactions and features of suicide bereavement largely from clinical case descriptions. Many of these reactions would later be observed in studies and survivors' accounts of their personal journeys following suicide loss. Cain's volume noted the bereavement reactions of guilt, rage, search for meaning associated with the death, identification with the person who died by suicide, incomplete mourning, as well as depression and self-destructive behaviors among the bereaved. Additionally, anniversary reactions, feelings of shame, stigma, abandonment, and preoccupation with the topic of suicide and suicide prevention efforts were listed. Although these published descriptions were available, a 1982 review by Lawrence Calhoun and his colleagues from North Carolina revealed a number of published studies of survivors, but also a particularly problematic issue. Specifically, among several methodological difficulties, not a single investigation had included a group of survivors of other modes of death to which suicide survivors of the study could be compared. Therefore, any attempt to specify unique grief features or differences among suicide survivors was impossible. As a result, Calhoun and colleagues were willing to venture only "cautious generalizations" derived from the sheer consistency of the themes could be offered. Perhaps three commonalities for suicide bereaved as compared to other bereaved individuals can be derived from this work. They suggested that suicide grief may differ from other causes in the prominence of feelings of guilt, a search by suicide survivors to understand their loved one's death, and lower amounts of social support following the death.

Following this important review, the number of studies slowly increased, with many including comparison groups and often other improved methodological characteristics. In 1993, John McIntosh, coeditor of a 1987 professional book on survivors, reviewed the modest control group literature and drew several conclusions about suicide grief. His conclusions were (a) though often intense, delayed, and complex, suicide bereavement is generally nonpathological; (b) current research supports more similarities than differences between individuals bereaved of suicide and other modes of death, particularly with accidental death survivors; (c) while a small number of grief reactions or characteristics of suicide grief possibly differ from other modes of death and may comprise a "survivor syndrome," the current research findings are inadequate to demonstrate the precise differences and the uniqueness of specific characteristics; (d) the course of bereavement over time following suicide may differ from that of other survivors, but (e) by some time after 2 years, grief differences are minimal or not apparent; and (f) the variables of kinship to the deceased, the quality and closeness of the relationship to the deceased, and the time that has passed since the death appear to be important factors in the suicide bereavement process.

These conclusions are not shared by all, particularly the suggestion that, though possibly existing, there is insufficient evidence for specific differences. Others have argued that present evidence is strong enough to support some suicide bereavement differences. One such author, Jack Jordan, a therapist who has written extensively on survivors, emphasized the strength of qualitative evidence to support three themes for suicide grief. Jordan identified these themes as feelings of guilt and associated experiences (i.e., shame, responsibility, blaming), attempts to find meaning in their loved one's death, and feeling rejected and abandoned by and feeling anger toward the deceased. Other writers have criticized the focus on generalizations with the possible concern that the tremendous individuality of suicide survivors' grief experiences will be overlooked.

Among several issues with respect to current survivors research, one of the most consistently apparent factors that affect grief and bereavement is the relation of the survivor to the deceased. This includes the kinship of the survivor to the deceased, as well as the nature of their relationship. The number of survivors studies has increased slowly over time. However, these studies most often compare survivors of suicide and other causes who shared the same kinship relation to the deceased and are not comparisons of general samples of survivors of suicide and other causes of death (i.e., representing a range of kinship relations to the deceased). Although inadequate studies have been conducted of any relationship category, the majority of studies are of a few kinship relations. These investigations have yielded some general issues. The most studied relationship group has been parents who have lost a child by suicide. These studies have shown guilt and related aspects (i.e., shame and stigma) as perhaps the most prominently

reported aspect of parent survivors' grief. The small literature on attitudes toward survivors has shown that parents are blamed and held responsible for their child's death, and they are liked less than parents whose child died by other means. Thus, parents feel responsible and guilty, and society seems to feel this way as well. Although personal accounts by parents often note a lack of support received from others following their child's death by suicide, research findings, including comparative groups, are equivocal. In the case of a child's death, both positive and negative outcomes in overall family adaptation have been noted, though parents surviving a suicide death may more often experience negative adaptation both in their family relationship and that with the other parent.

Spouse survivors are another frequently studied kinship relation, and nearly all of these studies involve widows. These studies are among those most likely to have observed more similarities than differences for spouses bereaved of various modes of death, particularly comparing suicide and accidental deaths. Spouse survivor studies often observed bereavement group differences, but little consistency in the particular grief aspects that differ emerged. A third group for which several studies have been conducted is children who are survivors of a parent's suicide. It should be noted that many of these studies have been conducted with an emphasis on mental health issues (as compared to a focus on grief and bereavement per se). Thus, studies of children who are parent suicide survivors have commonly observed that they are vulnerable and at high risk for mental health symptoms. With respect to bereavement, children have shown feelings of guilt for their parent's death and identification with the deceased parent. A special circumstance for this group of survivors was the often misleading or even false information provided to them by other family members, apparently in an attempt to protect them. This may include the mode of death, details of the death, or other aspects. The majority of these studies have included those who were young at the time of their parent's death (i.e., they were children at that time). Recent encouragement has also emerged for investigations of adult children who survive their parent's suicide.

While a small number of studies have been conducted with sibling survivors and therapists who have lost a client to suicide, the majority of kinship and other relationship categories in people's lives have not been investigated. Survivors are not exclusively those with family/blood/biological relationships. Interestingly, research by the Baton Rouge Crisis Intervention Center in Louisiana observed that individuals with 28 different relationships to the deceased sought and attended their formal suicide grief support groups.

Suicide postvention refers to the issues of treatment in the aftermath of suicide. Many communities provide general bereavement resources and sometimes separate resources for suicide survivors, usually in the form of support groups. Support groups may follow a variety of models, but typically the sharing of common loss experiences is a major aspect of the group. Survivors are able to realize they are not alone in their loss, that others feel or have felt the same way they do, and survivors further along in their grieving process provide hope and help to the new survivor as they attempt to heal from their own loss. Although not yet investigated, the personal experience literature clearly indicates that suicide survivors believe they benefit most from homogenous-loss support groups. That is, they believe they are most helped by support groups comprised exclusively of others who have lost someone to death by suicide rather than a mixed group of those who are grieving the loss of loved ones from various modes of death. In addition to support groups, some suicide survivors seek or receive individual as well as family therapy.

A final issue is survivors' contribution to suicide prevention and postvention. As noted, survivors have often been observed to seek understanding of and to make meaning from their loss. They also wish to spare others the pain they experienced following a loved one's suicide. In addressing these issues, survivors have shared their experiences in first-hand accounts; they have developed, participated in, and facilitated survivor support groups; and many have worked to raise public awareness and advocate for suicide prevention and survivors. A primary reason for the growth in attention to survivors has been the involvement and determination of survivors themselves to increase focus on this aspect of suicidal behavior. This has benefited survivors and the study and treatment of suicidal individuals as well. Consistent with Edwin Shneidman's characterization, this largest mental

health casualty area deserves greater research and clinical attention, not only to increase our understanding of the aftermath of suicide, but most importantly, to assist survivors' efforts to confront and heal from their loss.

Survivor Guilt

Survivor guilt is the term used to identify feelings of responsibility and self-blame in those who experience the death or significant loss of someone that they care about and wonder why they were spared. It is a common theme in literature and entertainment media and is seen both in response to individual losses and to catastrophic events in which many people are killed or injured, such as the Nazi Holocaust. Survivor guilt can be classified into two types: the first is existential survivor guilt. In this type, survivor guilt is frequently part of the post-traumatic stress disorder seen in soldiers who survive the roadside bomb that kills others in their armored vehicle. In such cases, the person is literally left behind when others have died. Survivor guilt is found not just in the survival of the death of others but in the guilt associated with how one escaped from difficult, life-threatening circumstances. The second type is content survivor guilt. In content survivor guilt, the focus is not only on surviving, but on what one did to survive. In either form, survivor guilt is a deviation from the question: "Why me?" to the question "Why not me?" Both questions arise from the same existential attempt to find meaning and re-establish a sense of control over events and circumstances outside of human control. This entry will describe survivor guilt as a form of grief, as well as discuss some of the ways to support those who experience it.

Guilt and Grief

Virtually every author who writes about loss and grief mentions guilt as one of the feelings experienced by those who are bereaved. In some cases, it is associated with an exaggerated grief response, typically that of depression. Guilt in survivors is seen as a part of the anxiety, depression, health impairments, and emotional challenges to those who have experienced significant loss. This is particularly true when the survivor felt protective of the deceased. For example, parents whose children die are at significant risk for survivor guilt, believing that they should have died rather than their child. Parents defer to the "natural order of things" with words like, "I should have gone first." This is partly a statement of the pain of grief, and largely a statement of self-blame for not having been able to protect the child. Children who lose a sibling frequently experience survivor's guilt, believing that somehow the parents' grief would be less if they had been the one to die instead of the sibling. These children may also experience relief that they did not die, adding to the survivor guilt experience.

Part of the pathology of guilt in survival is a skewing of the ability to relate to others about the survival event. The survivor may hold their guilt inside like a terrible secret. Their assumption seems to be that no one else will understand it, so the survivor needs to hold onto it so that the memory

will not be destroyed by others. For these survivors, the guilt becomes a shield to both protect them from other feelings and hold others away from the internalized pain about the survival event. Survivors frequently report subsequent difficulties in relationships with trust and expressing needs. There is a sense that others cannot meet one's needs, and that entering relationships out of need makes one vulnerable again to loss. Often, the survivor works hard in business relationships, but does not enjoy the work or its product because of ongoing feelings of unworthiness and impending doom. Guilt becomes a response to inhibit impulses and avoid fully engaging life. This attempt to control relationships and vulnerability is a normal defense mechanism for bereaved survivors.

Primary Identification

The term *survivor guilt* has been primarily identified with Holocaust survivors. Authors such as Aaron Hass and Elie Wiesel have written about the experience of guilt in the face of the death of friends and family members at the hands of the Nazis. Survivors, as well as their families, wonder why they lived while others died. Even more devastating, they wonder if their own drive to live contributed to the death of others. When resources like food and water are too scarce, securing them for oneself means denying them to someone else, and survival begins to be viewed as intentional harm to others. This example of "content survival guilt" reflects a belief, in fact an acknowledgment, that their survival came at the cost of lives.

Holocaust survivors have dealt with survivor's guilt in a number of ways. One of their prevailing feelings is a sense of helplessness. Survivors commonly try to deal with these feelings by attempting to control the future. They justify their survival to be witnesses to the atrocities, to make sure that their loved ones are not forgotten, to make sure it never happens again, and to create new families to continue the family line. These coping mechanisms help survivors find meaning in their own survival and existence. Viktor Frankl suggests that there should be no such thing as survivor guilt, only survivor responsibility, by which he means that survivors address the guilt and use it as witness to the atrocity in order to ensure that it can never happen again. Survivor responsibility answers the question, "Why did I survive?" with the determination to tell the story and to preserve the family and race. This attempt to find meaning is evident both in survivors of the Holocaust and in their children. This phenomenon is shared by others who experience survivor's guilt and subsequently engage in busyness designed to justify their survival.

Psychological Phenomenon

Issues of helplessness, control, and meaninglessness are also experienced by survivors of tragedies and losses other than the Holocaust. Many survivors experience guilt that manifests itself as the need to inhibit impulses and control responses to others. It is not unusual for survivor's guilt to manifest itself through depression or anxiety. Survivors who feel that their survival came at the expense of others may often withdraw from social relationships, experience physical complaints, disturbed sleep, mood changes, or all of the these conditions. In some cases, the depression is anger turned inward to avoid the personally unacceptable sense of rage at the cause of the tragedy. Anxiety is frequently accompanied by depression in survivor guilt.

An associated risk factor in survivor's guilt is that of suicide. Survivors who struggle with believing they have a right to be alive are at risk of suicide when depression and hopelessness prevail. There can be a sense that the only answer to the internal pain is personal death, a resolution to the issue of having survived the original event.

Therapeutic Responses

In the aptly named movie *Ordinary People* from 1980, young Conrad is depressed and suicidal after the drowning of his brother and the emotional withdrawal of his mother. When Conrad tells his therapist that he is being punished for doing "one wrong thing," the therapist asks what it was. Conrad replies that his sin was to hold on when his brother let go. The therapist's response to such a situation should help reframe the painful event to help the individual see the potential to share the story of the event. There is opportunity to make meaning out of their survival in a way that says, "I can live with that."

Survivor's guilt is often underreported because it is ignored or missed. Ideally, therapeutic

responses should begin immediately after a tragedy in which survivors are identified. These include providing the opportunity for the survivor to tell their story in a safe environment with unconditional acceptance and lack of judgmental response. Friends, family members, and first responders can all be listening ears to hear the stories of survivors. It is also essential to restore safety as soon as possible and to approach safety as an inherent right for all people. Reestablishing routines is also therapeutic for survivors. One effective method for meaning making and re-engaging decision making is the use of ritual. Examples include memorial services, dedications of hallowed ground, and ceremonies of commitment. Surrounded by family and friends, encouraging the survivor to tell the story as a part of the ritual can help the survivor to begin to tell the story and gain the confidence of sharing the event and pointing to the meaning in the story.

For those survivors whose survival guilt manifests as anxiety and depression, it is important to assess the scope of the feelings and refer to a mental health professional when the anxiety or depression prevents them from functioning normally. It is essential to assess for suicidal thoughts and plans as well. Some individuals experiencing survivor's guilt may require medical treatment with antidepressants, particularly during times of elevated risk of suicide.

The resilience necessary for survival is the key ingredient for dealing with survivor's guilt. Normalizing the response, treating any accompanying depression and anxiety, and validating the meaning of the survivor's life are essential. Helping survivors recognize that their survival means there has been both misfortune and fortune for them helps them acknowledge their right as well as their responsibility to continue.

Conclusion

Hope for the person with survivor guilt starts by talking about the event in an environment with supportive friends and family. The process of telling the story will help identify the meaning in the event, thus reframing the event from a source of guilt to having greater meaning and hope.

Symbolic Immortality

The concept *symbolic immortality* was developed in the research conducted on survivors of the atomic bombing of Hiroshima, Japan. Robert J. Lifton theorized that humans have a basic and compelling need for mortality transcendence, and that the quest for a sense of continuity that extends farther than one's natural life is a universal phenomenon made possible by self-knowledge of the inescapability of death. The need for, and the quest to achieve, a sense of connection and continuity was what became known as "symbolic immortality." This concept is one of the most widely used and influential thanatological theories, and it has important implications for a wide range of social scientific approaches to the study of dying, death, and the human response.

The work to achieve a sense of symbolic immortality plays an important role beyond that of providing a sense of continuity in the face of death; it is also an essential requisite of psychological well-being. Achieving a sense of symbolic immortality is one possible way of assuaging the certainty—and oftentimes fear—of death by transcending the most potent conception of what death signifies, namely the severed connection to the present and future and to the world of the living. To attain a sense of symbolic immortality is to become less susceptible to the crippling fears of dying and death; it is to be less threatened by the certainty of one's anticipated demise, and ultimately, to

approach death as a natural part of the cycle of life. The quest to achieve a sense of symbolic immortality is something all healthy individuals do, and in its absence, individuals risk developing psychic numbing or desensitization to life's experiences coupled with a loss of meaning. Studies of the survivors of Hiroshima's atomic bombing found that psychic numbing was pervasive, and that it led to a host of psychological problems in many who endured the experience. Achieving a sense of symbolic immortality helps not only to manage the terror and fear of dying, it also brings a sense of ontological order to the challenges and uncertainties of life.

It is theorized that people attempt to achieve a sense of symbolic immortality through fives modes of transcendence: the biological, creative, religious, natural, and experiential transcendent. Individuals can use one or multiple modes of transcending death, but what is crucial is that individuals attain a sense of continuity.

The Pathways to Symbolic Immortality

Biologic Symbolic Immortality

The most accessible means to achieving a sense of symbolic immortality is through the biological mode, most specifically through familial progeny, whether blood or adopted descendants. Having children provides parents with a bond to future generations in that decedents "exist" in the blood ties that bind their generation to the future. This pathway also offers individuals the chance to continue "living" in the memories of children, family members, and close friends and associates.

The biologic mode includes the sense of symbolic immortality derived from the transmission of cultural patterns from one generation to the next. When parents transmit cultural norms, religious or ethical doctrines, and worldviews that are specific to their ethnic, racial, or national identity, these social facts become an unbroken chain of shared ethos between the past and the future.

Creative Symbolic Immortality

The second pathway to achieving a sense of symbolic immortality involves artistic endeavors and/or creative acts, things that will outlive the decedent and have an influence over future generations. Robert J. Lifton envisioned the creative mode as one where personal accomplishments would be a lasting inspiration for other individuals long after one's death. Creative activities, such as works of literature, scientific endeavors, artwork, music, and/or any creative artifact that individuals might leave for others, are means to achieving a sense of symbolic immortality. Picasso, Van Gogh, Cezanne, Warhol, and Pollock are examples of individuals who have achieved an apagogic level of creative symbolic immortality in their *objet d'art,* as every successive generation rediscovers their work, engages their paintings by ascribing novel interpretations to them, and uses their techniques as inspiration for their own artistic creations.

A common method of achieving creative symbolic immortality is through one's work or career. The example of teaching as a vocation is one that provides a straightforward route to the sense of symbolic immortality. When teachers educate their pupils, they are simultaneously forming close relationships, albeit for the purpose of knowledge transfer, and this information transaction enables teachers to continue their existence in the minds of future generations. The same is true about the close relationship between the physician and patient, counselor and counselee, and the mentor and apprentice. These nonfamilial bonds can lead to a sense of symbolic immortality: creative symbolic immortality is an expression of the bonds of social influence.

Religious Symbolic Immortality

The third method of achieving a sense of symbolic immortality is through religious or theological beliefs and practices. To transcend death through religious means is to accept that one's mortal demise is not the end, and that there is continuity on a spiritual realm, whether that is the hereafter (heaven or hell) or some other manifestation of immortal existence. All major worldly religions have attempted to confront the existential problem death imposes on the human psyche through theological accounts of what happens after death. Many religions have an eschatological narrative and belief in a heavenly kingdom or realm of consciousness that adherents will experience after dying. Most religions provide adherents a security that death is a passage from this life to a much

more elevated and sacred existence. By accepting the spiritual transcendence of death, people can face their mortality without anxiety or terror. In essence, achieving a sense of religious or theological symbolic immortality serves as a mechanism of terror management given the continuity provided. Most Christian denominations propagate a theology of the eternal soul, believing that a decedent will continue to exist on a higher plane and in a superior form. In addition, the cycle of reincarnation and variations on the eternal soul characteristic of many Eastern religions play a similar role in responding to issues relating to human suffering.

Natural Symbolic Immortality

The fourth pathway is through the connection an individual might experience with nature, other living organisms, and the material world. This mode reflects a sense of deep connection between self and the natural environment because humans, as living organisms, are also part of a larger bionetwork.

Experiential Symbolic Immortality

The last type of symbolic immortality is experiential transcendence and is believed to be the most important expression of this phenomenon. Experiential transcendence relates to powerful and engrossing experiences where individuals are immersed to the point of losing themselves psychically, if only temporarily, by the sheer exuberance of the encounter. What is truly unique about this form of symbolic immortality is that it can manifest itself in each of the other types. For instance, the experience of childbirth could be a transcendent one for the parent(s) involved; likewise, the experience of a religious conversion, such as being "born again" in the Christian sense, or in Eastern religions, the experience of nirvana or enlightenment is an experiential transcendent one. This encounter can also occur in the creative realm, such as through one's music, artwork, or that of a charismatic performer. The act of sex, the moment of orgasm, and the intensity of intimate encounters also represent experiential transcendent moments. Finally, the use of psychotropic substances can also be a type of experiential transcendent phenomenon. These transcendent experiences are times when an individual might feel especially alive and spirited, and one where the individual is temporally absorbed in the present moment—not thinking about the past or the future.

Empirical Studies on Symbolic Immortality

Over the past 25 years, there has been extensive empirical research based on Robert J. Lifton's theory of symbolic immortality. The majority of these research findings suggest that humans desire a sense of symbolic immortality, including the quest to achieve this status, play influential roles in people's lives, not the least in assisting their management of the terror and fear of death, the most obvious implication of achieving a sense of symbolic immortality.

A 1998 survey of 420 Jewish Israelis, employing the Symbolic Immortality and Fear of Personal Death scales, demonstrated that those subjects who had a well-developed sense of symbolic immortality also had a protective shield against the terror and anxiety of death. These individuals were more likely to report low levels of fear about personal death.

Earlier research in the 1990s by Jean-Louis Drolet has revealed that the fear of death is lessened when individuals have achieved a sense of symbolic immortality. Finally, in the 1970s, Robert Kastenbaum found evidence that seemed to support the role of the biologic mode of achieving a sense of symbolic immortality. In a survey of 532 individuals, Kastenbaum reported that 90% of the sample agreed that people who have descendants, namely their own biologic progeny, have much less difficulty facing death than those who remain childless.

Threats to Achieving a Sense of Symbolic Immortality

The theory of symbolic immortality arose out of studies of survivors of the atomic bombing of Hiroshima. One of these findings was that many survivors existed in a state of "mimetic death," where they became psychically numb to life's experiences as a survival and coping strategy after witnessing the horrors of atomic annihilation. The atomic experience threatened their sense of symbolic immortality through the natural and biological modes because of the destructive power of the bomb, and the tens of thousands of immediate

deaths it caused. Consequently, the theory posits conditions where the quest to achieve a sense of symbolic immortality might be threatened or hampered because of extreme phenomena. For instance, massive environmental degradation caused by global warming, industrial pollution, and suburban creep could, in fact, affect attempts to achieve a sense of symbolic immortality through our connection to the natural world. A threat to achieving a sense of biologic immortality is the risk of nuclear war and the worldwide deaths that would likely result. Likewise, a threat to the religious mode of symbolic immortality might be increasing secularization and the rise of scientific rationality over the last century. Of course, the possibility of achieving a sense of symbolic immortality in other routes remains because of the multiple pathways to this end.

Symbols of Death and *Memento Mori*

Images or symbols that represent death have been incorporated into visual and literary culture since classical antiquity. They range from more overt personifications of death, such as a skull or the familiar black-hooded figure carrying a scythe popular at Halloween, to more abstract and subtle depictions, such as an hourglass or broken-stemmed rose. The term *memento mori* is a Latin phrase that may be loosely translated to "remember you must die," and the term is applied to visual or textual references to death, overt or symbolic, that are intended to remind the viewer of his or her own mortality.

Classical Antiquity

While *memento mori* may be Latin, the term was rarely used by the Romans, as they preferred the well-known *carpe diem*—seize the day. The intent was the same, however. The viewer was reminded to live life to the fullest, as death could strike at any moment. In Petronius's *Satyricon,* chapter 5, at a banquet hosted by Trimalchio, a slave brings in a silver skeleton with moveable joints. After the skeleton is tossed so that its limbs assume a variety of positions, Trimalchio ponders the brevity of life and exhorts his guests to enjoy life while they can, as they are all destined to one day look like the skeleton. The Romans also incorporated imagery that referenced the carpe diem theme into everyday objects. A 1st-century table top mosaic at Pompeii depicts a skull hanging from a carpenter's level. Its bony chin sits atop a butterfly that rests on a wheel of fortune. From the balance hang the garments of the wealthy on the left and a beggar on the right, indicating that death does not discriminate to class or occupation.

Medieval and Renaissance

While the Romans wanted to remind the viewer of his mortality so that he could live a full life, it was Christianity that incorporated a more cautionary note into the concept of memento mori. This more serious tone is linked to the medieval concepts of the "good" and "bad" death. If one found

himself unexpectedly on his deathbed, having lived a good and pious life would make the moment of death less frightening, as certainly an exemplary life would ease the passage to salvation. Those whose lives had been less than exemplary might not have time to repent their sins before they died, and thus their salvation would not be assured. Because, as in Roman times, death could strike without warning, the church encouraged the faithful to contemplate their mortality daily so that they would be ready to face death when it came. Representations of rotting and decaying corpses were especially popular, as they were a clear reminder of the fragility of one's corporeal self. Images such as *The Three Living and the Three Dead,* from the de Lisle Psalter (ca. 1300–1310, British Library), were especially graphic reminders of bodily decay, as the Psalter contrasts the images of three living men with those of three rotting corpses, complete with worms and ragged shrouds. Skeletons and decomposing corpses were also depicted on "cadaver tombs" especially popular in the 14th to 16th centuries. The tomb of Sir Roger Rockley (d. 1534) in Worsborough, England, and the tomb of Jean de LaGrange (1402) in Avignon are typical examples. As in the Psalter, the tombs contrast a representation of the whole body of the individual with that of the decaying corpse.

Personifications of death itself joined these other reminders of mortality in the 15th and 16th centuries. Hieronymus Bosch depicts death in one of his most well-known incarnations as a skeleton carrying an arrow in *Death and the Miser* (ca. 1490, National Gallery of Art, Washington, D.C.). Here, death attempts to squeeze through the bedroom door of an elderly miser who is trying to decide if he will accept the salvation offered by the angel at his right or be tempted by the demons lurking under the bed. Death depicted as a skeleton also appears in other didactic texts, such as *La Danse Macabre* (The Dance of Death), versions of which may be found well into the early 19th century. In this text, death is usually depicted interrupting the living at their work or leisure and attempting to lead them away from their earthly lives. The living are often surprised and reluctant to heed death's summons. The texts generally emphasize death's indiscriminate nature both as to time and rank. Death may just as easily come for an elderly monarch as for a young beggar child or middle-class merchant. Thomas Rowlandson's version injects some humor into these scenes. In *The Last Chase* (ca. 1816), death grasps an arrow as he sits astride his equally skeletal horse and grins merrily as he leads a group of men in the midst of a foxhunt off the edge of a cliff.

Less overt references to death and mortal decay were also popular in Dutch genre paintings of the 17th century. Although the predominately Calvinist Dutch did not favor overtly religious artwork as did their Catholic neighbors, they, nonetheless, believed that even the simplest genre scene or still life should have some type of didactic message. To that end, painters often employed *vanitas* symbols into their compositions, particularly still lifes to remind the viewer of the transience of life. These reminders of earthly vanity could draw on traditional memento mori imagery, such as the watch and skull included next to the violin, book, and other objects in Pieter Claesz's *Vanitas Still Life* (ca. 1630, Mauritshuis, The Hague). However, vanitas imagery could also employ even more subtle symbols, such as the peeled lemon or broken glass in Wilhelm Claesz Heda's *Still Life With Oyster, a Silver Tazza and Glassware* (1635, Metropolitan Museum of Art). Like the more well-known symbols, the lemon and glass nestled among the other luxury objects spoke of material wealth and prosperity. They would have been familiar to the prosperous Dutch merchant class and would have reminded them that despite the beauty of these objects, they, like the entire corporeal world, were transient and would decay.

In addition to these more public references to death found on tombs, in didactic texts, and in paintings, memento mori imagery could also be found on more personal objects used within the home or worn on the body. From at least the 14th century until the early 20th century, a variety of objects were produced with familiar symbols of death that at once reminded the viewer of their own mortality but also functioned to remind one of his or her duty as a mourner. These objects ranged from fans, gloves, and silver spoons with a small skull on the handle to snuff boxes shaped like a coffin with an inscribed hourglass on the lid. Mourning rings, pins, fans, and other commemorative objects were especially popular for both sexes in the 18th and 19th centuries and employed a variety of

familiar symbols: skulls, urns, hourglasses, weeping willows, and phrases: "behold death," "live to die," and, of course, "memento mori." Lockets, pins, and rings could be inscribed with the deceased's initials and have a compartment in which to display a lock of the deceased's hair.

The Modern Era

Although the skull and skeleton would long remain symbolic standards, a significant shift occurred during the 18th century in the types of symbols that were used to represent death. Enlightenment ideals that sought to replace ignorance and superstition with knowledge and the scientific method also influenced Christianity and the conceptualizations of death and dying. As medical science gained more control over the pain of death through medications, the terrors of the deathbed and the fears of damnation were de-emphasized in favor of a more peaceful end. This shift can be illustrated through Puritan gravestones found in the northeastern United States. Gravestones from late 17th and early 18th centuries often depict the familiar skull: an inverted pear-shaped head with wide holes for eye sockets and septum and a row of square teeth below. Throughout the century, however, the more terrifying skull transforms into the head of an angel: the skull becomes fuller and rounder, wings spring from the sides, the eye sockets are no longer empty and the rows of teeth become lips that curve into a gentle smile. The viewer is now reminded of death, not through a representation of the corruption of the body, but by a representation of a heavenly messenger.

In the 19th century, although death continued to be imaged as a skeleton dressed in a cloak and carrying a scythe, especially in popular culture, representations of death and mortality on the whole were more abstract and less frightening than depictions from earlier centuries. Many of these symbols borrowed from the more restrained neoclassical tradition; broken columns, down-turned torches, cloth-covered urns, and women dressed in classical garb standing mournfully at the graveside were popular motifs on tombs and gravestones, as well as on the numerous objects associated with mourning that were previously discussed. Romanticism, which in part emphasized the expression of emotions and the primacy of the imagination over reason, too, had its influence. The deathbed was often characterized as a blessed event where the dying would be released from the woes of the earthly realm. Death was discussed using metaphors of sleep and rest or traveling to a new realm. Sculptures of grieving angels now stood at the graveside, along with carvings of weeping willows, roses, or the popular disembodied hand that pointed heavenward.

Contemporary Symbols

As the 20th century progressed and the experience of death and dying was slowly removed from the domestic environment and from within close proximity of the living, these less-overt symbols also began to disappear. Modern graves generally do not incorporate memento mori imagery. Symbols of death did not disappear altogether, however. The November celebration of the *Dia de los Muertos* (Day of the Dead) in Mexico keeps alive many of the traditional references to mortality. The yearly festival, which honors deceased friends and relatives, incorporates the familiar motifs in a variety of ways. Small shrines are set up in the home with images of the deceased and candles and offerings of food and drink. Special toys, baked goods, and chocolate candies are fashioned into skeletons, skulls, or coffins, and these too are left in honor of the dead. Although the often whimsical or comical treatment of these objects belays the terror of depictions from earlier centuries, they, nevertheless, function in the same way: the living are reminded of their own mortality.

Contemporary artist Damien Hirst provides a final example of the tradition of memento mori imagery but with an intriguing twist. His *For the Love of God* (2007) is a human skull encrusted with over $1 million worth of diamonds. The traditional symbol of mortality and bodily decay has been transformed into an object of glamour and wealth. Perhaps like the Dutch Calvinists from the 17th century, Hirst intends to remind the viewer of both the luxury of this world, and the inevitability of leaving it all behind.

Taxidermy

Taxidermy is the art of preparing and preserving the skins or parts of the bodies of animals, birds, reptiles, fish, or other creatures, and then mounting them in such a fashion so as to appear in a lifelike state. The craft of stuffing animals is centuries old, but the process was accomplished in a crude fashion until the late 18th century, when somewhat more sophisticated procedures were employed. By the early 20th century, modern taxidermy had evolved and was capable of producing extraordinarily lifelike specimens. Taxidermy has long been popular in the United States because Americans perceive a certain organic beauty in animals and birds, even if dead. Taxidermy converts the corpses of deceased creatures into seemingly live statuary, but frozen in time and place. Taxidermy products are quite diverse and can be categorically divided into eight different varieties.

Taxidermy is both a zoological art form and a thanatological art form. It is a zoological art form in that it produces mounted specimens of animals, birds, and fish in their natural state for the edification and pleasure of those who view them. The mounted creatures may serve a number of manifest functions, including education, enlightenment, entertainment, amusement, utility, attracting interest, and impression, mood, atmosphere, and emotion management. From the thanatological perspective, the practice of taxidermy has latent functions that seek the refutation of death. One latent function of taxidermy is that it serves to acquaint the viewer with the reality of death. Even though the animal is dead, the skilled taxidermist can restore symbolic life to the creature by giving it the impression of both viability and reanimation. Taxidermy can be seen as transcending death by projecting the image of life.

In the past, taxidermy was categorized as a socially marginal art, but today there is a strong emphasis on aesthetics in mounting animals. Taxidermy involves a number of technical protocols, such as tanning the skin, inserting and properly positioning glass eyes into the eye sockets of the form, fitting the hide to the form, and sewing the skin to tighten the hides on the form. Taxidermy is a unique enterprise in that it seeks to create nature in the form of dead animals, imitate art in the shape of organic statuary, rather than art imitating nature.

Taxidermy in American Life

Taxidermy has a strong and visible presence in American culture, as it appears in television, movies, commercial establishments, household items, clothing, and even in humor. Taxidermy has been institutionalized as an American folk craft. At one time, taxidermy skills were so desirable that the Boy Scouts of America awarded a merit badge to scouts who mastered these skills.

Taxidermy can be an avocation, occupation, or both. Many individuals originally take it up as a hobby, but often after acquiring and perfecting their skills and developing a sense of aesthetics and artistic creativity, they pursue the skill commercially. The most remarkable aspect of taxidermy is the fact that the great majority of taxidermists acquire their expertise via mail order correspondence courses.

Taxidermy and Cultural Utility

Taxidermy specimens are employed in various configurations for different social purposes and serve several functions in American culture. An examination of the various categories of taxidermy demonstrates the diversity of forms and functions that taxidermy manifests. Taxidermy can be divided into two distinctive levels of cultural goals:

1. *Specific*. The specific goal is to seemingly restore life to dead creatures so that they can be viewed, scrutinized, and admired in their natural appearance at close hand. The mounted specimens provide that opportunity.
2. *Diffuse*. The goal is to achieve a more subjective result. The intent is to alter the cognitive attention or emotional state or mood of the viewer upon viewing the specimen.

Patterns of Social Purpose

Both of the previously mentioned goals can be further divided into four patterns of social purpose, namely (1) interest/attention management, (2) impression/image (persona) management, (3) impression/atmosphere (ambience) management, and (4) emotional/mood management. Each of these patterns involves the management of variant types of perception. The resulting typology consists of eight subvarieties of taxiderminological enterprise with widely varying motivations and products. These include:

1. Scientific or display taxidermy
2. Trophy taxidermy
3. Craft (utility) taxidermy
4. Novelty taxidermy
5. Advertising taxidermy
6. Fashion taxidermy
7. Decor or decorating taxidermy
8. Nostalgia taxidermy

Instrumental Cultural Goals

Instrumental taxidermy involves mounting dead creatures for four special purposes, namely to inform, to impress, to perform tasks, or to amuse. To achieve these goals, the creatures must be preserved in a naturalistic and lifelike fashion to accomplish the first two purposes, but in a convoluted or bizarre fashion to accomplish the last two.

Scientific or Display Taxidermy

Scientific or display taxidermy could be called museum taxidermy. From this perspective, taxidermy is a scientific or naturalist craft and art. The mounted specimens are interesting, enlightening, and educational. This type of taxidermy is used to create, manage, or manipulate interest in zoological topics. It was through such educational interest that taxidermy first entered the American home. A recent variation of the traditional wildlife museum is having mounted animals placed where blind persons, especially blind children, can feel them. Visitation that involves feeling the animals is called sensory safaris.

Trophy Taxidermy

One of the more commonly encountered forms of taxidermy in the United States is that of trophy taxidermy. In some parts of the United States, such as in the South or the West, a great many homes, especially in rural areas and small towns, will have a mounted deer head or a large mounted fish on the wall. These mounted trophies offer tangible, visible evidence of the individual's hunting or fishing success. Such trophies may also be found in restaurants or other places of business. Mounted exotic animals from Africa or Asia may be displayed as status symbols of affluence, foreign travel, adventure, or danger.

Craft or Utility Taxidermy

Early in the evolution of taxidermy, practitioners perceived that there was a utilitarian dimension to the art, and they designed and produced a wide array of useful articles using the remains of dead beasts to shape and form a variety of items for household purposes.

Utility taxidermy might include such useful artifacts as elephant feet waste baskets, lamp bases made of bird and animal parts, or knife handles made of deer feet. The American national character has a penchant for the unusual, such as dead animals being converted into artifacts.

Novelty Taxidermy

Just as some paintings and sculpture may be compelling as an object of attention, taxidermists are capable of producing artistic creations with similar characteristics—novelty taxidermy. By reassembling mismatched portions of dead animals, new and bizarre species are created that have no real live counterparts. Such taxidermy specimens may assume various modal configurations. The production of such chimeras is sometimes referred to as rogue taxidermy.

Another form of novelty taxidermy is *tableaux-morts* or anthropomorphic taxidermy. In this mode, a group of small common animals, often kittens, puppies, or rabbits, are mounted in human group situations depicting events such as weddings, poker games, or a uniformed band marching down the street with tiny musical instruments.

Diffused Cultural Goals

Taxidermy is used to achieve generalized goals, such as creating a mood or state of mind, or to influence the perception and judgment of the observer. The intent is to enrich the visual inventory of an image and thus influence the viewer's interpretation.

Advertising Taxidermy

Mounted animals, birds, fish, and especially exotic creatures, are eye catching. Accordingly, they are often used as displays and for advertising purposes to attract the attention of prospective customers. Many popular magazines feature ads for products in which animals are included. These are frequently lifelike mounted animals, which are sometimes trademarks.

Fashion Taxidermy

The use of animal parts can also be used in costume, and the animals preserved by taxidermy may significantly add to the construction. Clothing is a costume, and costumes augmented by taxidermy produce a special kind of costume. By wearing a particular costume, the individual can create and project a desired persona. Accordingly, Americans and members of many other societies like to wear costumes that utilize various zoological elements, such as fur, feathers, hides, or even portions of the creature itself. Animal, bird, reptile, or fish skins and parts have always been used as status symbols to create a persona or convey a social message.

Décor Taxidermy

In the early development of taxidermy, mounted specimens of animals, birds, fish, or reptiles appeared in museums and business establishments. They quickly moved to the home, the presence of which was initially rationalized as educational and scientific. Hunting trophies in the form of animal skins, hides, and horns followed. Whether it is in home or commercial establishments, taxidermy products aid in creating an ambience and, thus, a way of managing the impression of others.

Nostalgia Taxidermy

The death of a pet can be emotionally traumatic for many individuals. For such individuals it is difficult to let go, and they seek to retain something of their beloved companion, if even nothing more than a dead body. Nostalgia taxidermy is a way of managing grief and dealing with the emotional loss of the pet. The dead dog, cat, or horse can be mounted and retained. The bonds will not be totally broken as long as the taxidermy effigy of the animal can be seen, touched, and stroked. In recent years, some taxidermists have offered the

service of freeze-drying dead pets. By preserving the pet, memories of the past are preserved.

Terminal Care

Terminal care is health care given to people at the end of life when curative measures have been exhausted and supportive palliative care is more appropriate. Terminal care focuses on maintaining good quality of life, relief of suffering, and physical, psychosocial, and spiritual support during the last days and weeks of living.

Recipients of Care

The terminally ill person and family or significant others are the focus for terminal care. Professional caregivers provide the physical care for the patient, or assist the family in giving care, but the psychosocial and spiritual care is appropriate for all. The patient may be in a hospital, a nursing home, an inpatient hospice, or at home. A criterion for hospice care is a life expectancy of six months or less as determined by two physicians. Though hospice personnel are well known for excellent end-of-life support, well-trained professionals can provide appropriate terminal care to patients in all the previously mentioned settings.

Providers of Terminal Care

The providers collaborate with the patient and family to give comprehensive, holistic, compassionate care. The head of the health care team is the physician who determines that curative care is no longer indicated and that the patient is terminally ill. The physician, in consultation with the patient, family, and other caregivers, orders medications and other therapies for symptom relief. In home care, a family member is usually the primary caregiver, with assistance from other relatives and friends or professionals. In the inpatient setting, nurses are the primary caregivers, but family members are often involved there as well. A social worker assists with financial concerns, evaluates the home for adequate facilities for home care, and may serve as a counselor. The pharmacist is available for consultation regarding medications and dosages, particularly for pain management. The chaplain provides spiritual support. A physical therapist may assist the patient to retain strength and flexibility to increase comfort. Professionals from other specialties may also be called in to offer nonpharmaceutical alternative approaches for relaxation, pain management, and psychological support. These may include a music therapist, an acupuncturist, and/or a specialist in healing touch, massage therapy, and/or guided imagery.

The majority of patients in hospice care have a diagnosis of cancer. Other diagnoses include chronic respiratory disease, congestive heart failure, stroke, Parkinson's disease, amyotrophic lateral sclerosis (ALS), multiple sclerosis (MS), and congenital syndromes that shorten life. The terminally ill patient may also be the victim of trauma

or another sudden event for whom curative care is no longer effective or appropriate.

Aspects of Terminal Care

The focus of terminal care is comfort. The interventions are directed toward that goal. Some have described terminal care as necessary when "nothing else can be done." It is helpful for the family and caregivers to recognize that terminal care involves "doing" many things to bring good quality to the patient's last days.

The initial assessment of the terminally ill person includes a determination of distressing physical symptoms: emotional, social, and financial concerns; worries about "unfinished business"; anxiety about symptoms and approaching death; and spiritual concerns. In the ideal situation, every effort is made to relieve both physical and emotional suffering.

Physical Symptoms

Physical symptoms must be addressed first. If the physical symptoms are controlled, the patient is better able to be involved in the psychosocial, emotional, and spiritual tasks that are of concern.

In terminal illness, several body systems may begin to fail and create problematic symptoms. Pain is usually the most important symptom that concerns the patient and the family. Some sources of pain are the primary disease, metastases, immobility, respiratory distress, or infection. Some other symptoms are as follows:

Nausea, vomiting, and loss of appetite

Dehydration

Urinary and bowel incontinence

Constipation

Reductions in ability to walk, talk, or hear

Skin breakdown

Mental confusion

The professionals who care for the terminally ill sensitively and thoughtfully evaluate the symptoms that are bothersome and, in concert with the patient and the family, determine the most helpful interventions. Because pain is the overriding concern, the appropriate medications and dosages are crucial to management. The terminally ill patient may need high dosages of narcotics to get relief, but he or she usually wants to remain alert as well. It is a balancing act to assure both. Worries about addiction are not appropriate in a terminal care situation.

Terminal care is not curative, but curative interventions may be used as palliative interventions. For instance, if a tumor is large and causing pain or other symptoms, radiation or chemotherapy may be used to reduce the size of the tumor. There is no expectation of cure with these interventions. Similarly in terminal care, intravenous fluids are not used routinely. At times, however, dehydration may become problematic and specifically cause mental confusion. Intravenous fluids may be indicated to relieve this troublesome symptom.

Emotional Concerns

Emotional care of the terminally ill and their family members is of primary importance. Emotional distress reduces quality of life significantly. Everyone involved in terminal care has the potential to identify emotional concerns and provide kind and compassionate listening, support, and encouragement.

The following are some of the emotional concerns that may be expressed by someone who is terminally ill:

Anxiety and fear of approaching death

Worries about the financial and emotional well-being of loved ones

Regrets, "unfinished business"

Anger at God, self, and others

Denial of the prognosis

Inability to communicate fears and worries

Depression

Some of the emotional distress may be relieved with medication for depression and if pain and uncomfortable symptoms are relieved. Though

patients may not be able to talk openly with family members because of concerns about making them sad or uncomfortable, they may talk with outside caregivers or friends. One may earn the privilege of sharing this important communication by establishing a warm, trusting, and nonjudgmental relationship in all patient interactions.

Family members also need a great deal of emotional support as they anticipate the approaching death. They need a listening ear, a shoulder to cry on, and a break from the constant stress of giving care and facing the suffering of their loved ones. Professional caregivers and friends help provide emotional and physical respite to them.

Interpersonal Relationships

In the last days of a terminal illness, the patient usually has decreased energy and may not be able to interact well with others. Participating in previously enjoyed activities is impossible. At times the patient will withdraw and gradually reduce outside contact to just a few immediate family members and caregivers. The caregivers support this need by allowing time for the family and patient to be together and protecting them from outside visitors who may not be needed at that time. Well-meaning friends can be encouraged to send cards, bring food, or spend time with the family members who need support and conversation. Wise caregivers can gently affirm to the visitors that they are serving the patient by their support of the family.

Conversely, some friends and distant family may avoid visiting the patient because of discomfort being around the terminally ill and uncertainty about what to do or say to the patient or family. Caregivers may have the opportunity to intervene by speaking with friends and family whom the patient would like to see and assuring them that "just being there" is all they need to do.

Spiritual Care

Some people are religious and find great comfort in their religious beliefs as the end of life draws near. Family members also find comfort and hope in their faith that they will be reunited after death with their loved one. Support from their minister or the agency chaplain is important to them and necessary for making their last days rich and meaningful.

The patient may be at the other end of the spectrum and be angry with God and frustrated with the platitudes of religious groups. An effective spiritual advisor allows for the expression of emotion and finds ways to encourage and move the person toward some satisfying resolution of conflicts if at all possible in order to make the last days as peaceful as possible.

Some do not have a formal religion but will find spiritual encouragement from reflecting on their lives and the contributions they may have made to others and to the community. They may be comforted by meditation, music, beautiful art and writing, or a number of other things that give meaning to life. The caregiver facilitates and obtains what the patient needs for spiritual support.

Ethical and Legal Issues in Terminal Care

Terminal care implies that all concerned are aware that the ill person has a short time to live. Resolution of certain legal and ethical issues will enhance this period for both the patient and the family.

In many situations of terminal illness, the patient has a living will and durable power of attorney for health care document, especially if the care is being delivered in a nursing home or hospice. This written, notarized declaration guides the family and the health care providers to the patient's preferences regarding care. In terminal care, the patient and the spokesperson for the patient have usually determined that no further extraordinary measures will be undertaken. This opens the door for the philosophy of comfort and relief of suffering to be the overriding goal of all decisions in care, including artificial nutrition, resuscitation, and artificial respiratory support by ventilator. It is important to note that the patient and the spokesperson may change their minds about their decisions at any time. Open communication among the patient, family members, and the physician will allow for discussion about the futility of extraordinary care and will assist in bringing all to a consensus about comfort care.

In hospice or comfort care, if the patient is unable to eat and drink, there is no additional effort to force nutrition. Research in hospice care has shown that as the body begins to "shut down" there is no need to force nutrition and fluids. Patients do not show signs of discomfort other

than dry mouth and lips. The caregiver helps relieve these symptoms by offering ice chips, gently swabbing the mouth with a moist sponge, and lubricating the lips frequently. As death approaches, many patients seem to breathe more easily and have less respiratory discomfort when their lungs do not contain excess fluid. In other words, "letting nature take its course" provides the patient with a seemingly more comfortable dying process than using artificial support.

One dilemma for the patient and the family may be the fear of stopping treatment too soon. The health care providers can reassure them that the disease process has overcome all the treatments currently available, and that they have done all that is possible to give the patient a chance to live longer. When the family members and the patient consider the choice between extending suffering versus providing a comfortable quality of life, most are satisfied with the choice of no more attempts at curative measures.

Indicators of Approaching Death

Communication is extremely important between caregivers and the family in the care of the terminally ill, and no more so than when death approaches. The family will often begin to ask about the signs that the end of life is near. Some of the possible changes are as follows:

Confusion and agitation

Unresponsiveness

Cool and bluish extremities

Purplish coloring of the legs

Dark urine

Incontinence

Irregular breathing

Chest congestion, "death rattle"

Glassy unfocused eyes

When possible, the professional caregiver will be nearby and provide private time for the patient and the family to be together in the last moments and as long as possible after death. The caregiver provides comfort and support to the family as long as necessary at this crucial time.

Terminal Illness and Imminent Death

The time of terminal illness and imminent death is almost always an exceptionally difficult period, both for the patient and for the family and friends. It was not always like that in the past. As recently as a century ago, dying was commonly regarded as a simple fact of existence, and the end of life was usually treated more pragmatically, often

stoically. Currently, the prospect of dying looms large and terrifying, and much of that is due to the fact that our society is emerging from a long period, perhaps five decades or more, of denying the universality of death, and of making it a taboo subject—an action that has deprived most people of any opportunity to build and strengthen preparatory and coping strategies that they might otherwise have developed.

This entry provides a brief overview of the history of social attitudes toward terminal illness and the end of life—a history that materially affects our current attitudes and coping strategies. It also offers an analysis of the main factors contributing to the heavy psychological burden of imminent death and outlines some possible strategies that may enhance coping.

Denial of Death: A Brief History

There is no universally accepted measure by which we can assess a culture's attitude to death. Therefore, any description is of necessity partly subjective. However, it seems that the separation of the process of dying from the daily business of living may have accelerated—certainly in Europe and the United States—after World War II. This change in attitude may have its sociological origins in the move away from war as a solution to political problems after the massive slaughter of the two world wars. At the same time, in the late 1940s, expectations of health were dramatically raised with the advent of effective medications, particularly antibiotics, curing some infections that had previously been common causes of early death. The power of these first antibiotics heralded a wide and major change in the effectiveness of medical treatment in many common diseases, and thus raised public expectations of a longer and healthier life. By the late 1950s and early 1960s, medical successes and breakthroughs, augmented by intense media coverage, raised general expectations of cure for so many disorders that more people expected miraculous cures for most conditions, even terminal illnesses. This atmosphere of unrealistically high expectations made it more difficult for the patient and the family to accept death.

Furthermore, the process of dying became institutionalized, to some extent, and a part of the field of specialists and experts. In many urban centers, death occurred in a hospital or nursing home in over 75% of cases, and the role of family and friends in supporting the dying person became subordinate to the expertise of medical and nursing staff. There is, of course, little intrinsically wrong with that, but it did foster the perception that family and friends had no place or role at the bedside of the dying person.

Simultaneously, most lives in the developed world were being evaluated by criteria that had become more materialistic. Again, there is nothing intrinsically wrong in summing up a person's life solely by his or her wealth or success, be it artistic, social, or financial, but it does increase the difficulty of accepting the ending of life—a moment at which the person will clearly be separated from the material symbols of worth.

Another factor is the social marginalization of the sick and the elderly. Developed nations from the 1960s until recently tended to treat the sick, the elderly, the infirm, and the dying as people on the margins or fringes of society and not as part of the mainstream. Whether or not this is regarded as uncharitable and ultimately deleterious for that society as a whole, it has consistently been an observable phenomenon and is another factor that makes things difficult for seriously ill and dying patients when they are unable to contribute to society and the workforce and are consumers of health care and support.

Along with all of these factors, there was also a general re-evaluation of the role of religion. Even as recently as a century ago, religions shared similar views of a single God, of some system of divine justice, and of some form of an afterlife. Even though religions clearly had major differences of opinion and often waged major wars against each other, the somewhat monolithic view of a God and heaven was a form of support that chaplains and priests could easily use to support the dying person. Although that support still occurs, it is less common, and more personal and individual views of religion and spirituality make it more difficult for people who may not hold the same view to support the patient and administer comfort.

Taken together, these factors—high expectations of life and health, the "expertization" of the dying process, materialistic evaluation of a life, marginalizing of the sick and elderly, and the

repositioning of the role of religion—increased the separation of the process of dying from the daily business of living. It is that separation that underlies much of the psychological burden of dying.

Minds and Hearts

There is a difference between the rational and intellectual understanding of the ending of life, and the emotional acceptance of that fact. Most people acknowledge as a rational and intellectual concept the fact that that every human life is finite. Notwithstanding any belief that a person holds about an afterlife or a kingdom of heaven, most of us acknowledge the statement that every human biological life ends in a physical death. The problem is that while we all recognize that intellectually—as an accepted cognitive fact—most of us do not live our daily lives accepting that concept emotionally. There is a disconnect between the head and the heart, a gap between thoughts and feelings. Most of the time, that disconnect is subconscious and invisible, and does not cause any problem. However, in a terminal illness and at the imminent approach of death, that gap between the intellectual acceptance of mortality and its emotional acknowledgment as a personal event often causes problems that may become severe. Hence, in the final phase of life, a considerable problem is created by the gap between mind and heart, and a great deal can be achieved in the support of the dying person by attempting to reconcile the rational with the affect, reducing that gap and the distress it causes.

A Practical Way of Thinking About the Process of Dying

It is helpful to compare the process of dying with a journey. In the late 1960s, Elisabeth Kübler-Ross proposed that there were five stages of dying, namely denial, anger, bargaining, depression, and acceptance. Although initially widely adopted, this has been found in practice to be often unhelpful in assessing the patient's situation and in predicting future events. A more practical system has been proposed that considers the process of dying as having three stages: the beginning (acute phase), the middle (chronic stage), and the end (final stage).

The Initial Phase

As the person first realizes that terminal illness and death are not merely abstract concepts but are realities as part of the future, he or she is likely to react in the way he or she has reacted to major vicissitudes in the past. Thus, people who are commonly angry will show anger, people who often cope by using denial will use denial, and similarly with the wide array of reactions that all humans experience, such as guilt, humor, bargaining, disbelief, or displacement activities, such as undertaking a new task or project, for example. Of paramount importance is that fear is an almost universal response to the diagnosis of terminal illness. Fear and anxiety about the future are so common that it would be fair to call them normal reactions to this situation, and if a person has no anxiety at all, it would be reasonable to wonder whether they truly understand their situation.

Perhaps the most important aspect of the person's initial reaction to terminal illness and imminent death is that the reactions displayed are characteristic of the person, not of the stage of the process. The way in which a person responds tells us what kind of person they are; it does not tell us what stage the process is at.

The Chronic Phase

For the duration of the terminal illness, usually the acute reactions of the first phase become less intense. The emotions are likely to become part of the person's background state, and it is in this phase that depression is particularly likely.

The Final Phase

The final phase can legitimately be defined as acceptance of imminent death—be it overt and openly expressed or covert and not discussed openly. Some people simply do not discuss their feelings about major issues, and quite often a person may know that he or she is dying but is quite comfortable not discussing it openly.

Fears Associated With Terminal Illness

Fears about dying are multiple, and it is likely that no individual will have precisely the same list of fears in the same order. A complete catalog is probably unachievable, but the most common major fears have been summarized in the matrix (Table 1).

Table 1 Common Fears About Dying

Physical	*Psychological*	*Social*	*Spiritual*
• Pain • Nausea • Disfigurement • Disability • Other physical symptoms	• Dementia • Loss of control • Personality change • Mental incompetence • Depression • Delusions	• Irritability • Anger • Loss of good decision making • Dysfunctional relations with family • Sexual problems	• Existential • Punishment in an afterlife

Provision of Help and Support at the End of Life

Help and support for a person facing a terminal illness and imminent death can be offered more readily than most people suppose. The central objective is to acknowledge the emotions that the person is experiencing—which means listening to them and then showing that they have been observed and heard—and deal with any practical problems and pragmatic aspects of the person's situation as much as possible. These two objectives, acknowledgment of emotions and addressing practical problems, are complementary.

The most important technique in acknowledging any emotion is known as "the empathic response," and it is a technique that can be used by any willing person. It is not an inborn gift given only to a few. It comprises (a) identifying one of the emotions that the person is experiencing, such as fear, shock, disbelief, or anger, and (b) identifying the source of the emotion (which is usually the situation itself or a particular piece of bad news). Then it is important to respond in a way that shows you have made the connection between the first two responses. Empathic responses are statements in the form of: "This is really tough for you, isn't it?" or "I can see you're feeling really low" or "This must be very difficult for you." Framing an empathic response shows the patient that you have noted their feelings and what has caused them; such a response will be nonjudgmental and supportive. Only after the emotions have been acknowledged can the friend or family member address the practical issues and make realistic offers to ameliorate the situation.

Many individuals find it threatening to talk about the prospect of death and thus avoid discussion of plans and arrangements. In that situation, it is useful to discuss the future as a hypothetical situation ("What would you like to do if…"), thus maintaining a hope for the best outcome while simultaneously preparing for the worst.

The "what if" approach has been shown to be less threatening and can and should be used early in the terminal illness, long before emergencies arise. As has often been said, supporting someone in a terminal illness at the end of their life is one of the most important and valuable things that one human can do for another.

Terrorism, Domestic

Domestic terrorism is a common description of a type of extremely violent activity against a

population for domestic political or religious purposes. There is no common precise delineation of it. It is held to be illegitimate. In the following text, the definition, significance, and justification of terrorism are discussed and examples are presented.

Definition

Although the notion of terrorism and derivative expressions, such as terrorists, are frequently used, both in professional frameworks and in daily discourse, there is no commonly accepted, adequate definition of that notion. Definitions of terrorism were abundant long before September 11, 2001, and the proclaimed War on Terror. For example, by 1988 one publication enumerated 109 different definitions of that concept.

There are several reasons for the multiplicity of definitions. First, international conventions have been formulated, signed, and often ratified, banning activities of certain types. Therefore, the notion of terrorism has been used with respect to certain types of such activity, rather than all of them. The first international convention in 1963 was on "offences and certain other acts on board aircrafts," a 1988 international convention was "for the suppression of unlawful acts against the safety of maritime navigation, a 1997 international convention "for the suppression of terrorist bombings" was related to using explosives and other lethal devices in public places, and a 2005 international convention "for the suppression of acts of nuclear terrorism" was related to nuclear reactors and power plants.

Second, new forms of activity sometimes appear that constitute cases of terrorism. Hence, the 2006 Council of Europe Convention on the Prevention of Terrorism, for example, defined the term *terrorist offense* as an offence defined under any of the international conventions on terrorism that is in force.

Third and perhaps most important, definitions of terrorism have been proposed that would exclude certain types of activity on grounds of political or ideological considerations. The notion of being a terrorist is universally understood to be pejorative. Hence, when facing a definition of terrorism in terms of certain kinds of actions or activities, attempts are often made to exclude from the definition some cases that fall under the term as defined, but involve favored parties. The 1999 United Nations General Assembly resolution 49/60, "Measures to Eliminate International Terrorism," defined terrorism in terms of "criminal acts intended or calculated to provoke a state of terror in the general public, a group of persons or particular persons for political purposes." It goes on to state that such acts are "unjustifiable, whatever the considerations of political, philosophical, ideological, racial, ethnic, religious or any other nature that may be invoked to justify them." People who hold the view that acts of the described nature are justifiable on, say, some religious grounds, will oppose that resolution and try to exclude from its application whatever they believe is religiously justifiable. The 1994 Code of Conduct for the Fight against Terrorism, adopted by the Organization of Islamic Conference, during the 7th Islamic Summit in Casablanca, Morocco, added to an ordinary depiction of terrorism a proviso with respect to the rights of people under occupation to struggle for independence and self-determination. A similar condition is mentioned in Article 3 of the 1999 African Convention on the Prevention and Combating of Terrorism, accepted by the Organization of African Unity during a meeting in Algiers, Algeria. The combination of a definition of terrorism with a restriction imposed on its application is tantamount to proposing an alternative definition of the notion.

Definitions of terrorism share the following conceptual ingredients or conditions:

1. It is a practice of violence.
2. The practice involves acts of killing and injuring people who do not jeopardize the life or health of the agents of the practice, as well as threats to perform such acts.
3. The practice is used against members of a certain population.
4. The practice is used in a regular manner.
5. The practice is used in order to terrorize that population.
6. The practice is used in order to change the political situation by means of terrorizing the population.
7. The practice is used on political, ideological, or religious grounds that justify it in the eyes of its agents.

Some definitions of terrorism include additional ingredients that are not conceptual but rather contingent. The practice of terrorism can appear in their absence.

8. The practice is used by an underground organization.

9. The practice is used against members of a certain population in a random manner.

Condition 8 is not necessary. Osama bin Laden and associates declared in their 1998 World Islamic Front Statement that jihad (the holy war or struggle) is an individual duty of Muslims. Their followers can practice terrorism without being organized as such. On the other hand, condition 8 naturally obtains when the practice involves criminal activities of certain types. Condition 9 naturally obtains when the practice of terrorism involves suicide bombers operating in public places. However, it is not a necessary ingredient of terrorism. One can imagine attempts to terrorize a population by announcing a list of places or areas to be targeted.

The previous list of conceptual ingredients of terrorism, 1 through 7, does not include an attribute that appears in many definitions. Condition 2 is couched in terms of people, victims of an act of terrorism, who do not jeopardize the life or health of the agents of the act. Often, a similar condition employs the distinction between combatants and noncombatants, familiar from the Just War Doctrine and international laws of armed conflicts. Condition 2 is not phrased in terms of noncombatant victims because acts of terrorism can take place outside the confines of a war between military forces, including guerrilla units, and still be directed against people in military uniform, where all the other conditions also obtain.

The definition of terrorism to be used here allows practices of a local nature and practices of an international nature. In the former case, the political change sought by practicing terrorism is of a local nature and usually the victims and the population to which they belong are locally identifiable. In the latter case, both the ends and the means are of a broader nature. The present entry is related to the former type of terrorism.

Justification

Acts of local terrorism are never morally, legally, or religiously justifiable. A performed act of terrorism involves agents of the practice of terrorism killing or injuring the victims of the practice. The victims do not jeopardize the life or health of the agents. The act of terrorism is not an act of self-defense, in any reasonable sense of the term. Killing children, because eventually they will serve as conscripts who often do jeopardize the life or health of people, is not self-defense. Nor is any instance of killing people because they are compatriots of people who do often or even presently jeopardize the life or health of people.

Thus, the victims of the practice of terrorism are merely used by the agents of the practice in order to terrorize people and thereby cause a certain political change. Using human beings as a mere means in the pursuit of an end, be it personal, political, religious, or any other reason, is morally wrong. It is incompatible with the duty to respect the human dignity of the people who are the victims of the practice of terrorism. It utterly blurs the distinction between human beings and tools (for information relating to common attempts to justify acts of terrorism on grounds of the fact that their agents are freedom fighters, see the "Terrorism, International" entry).

Consequentialist considerations might suggest delineation of certain extreme conditions that, if obtained, would justify terrorism of some form. However, it has been shown that such conditions are never obtained, and therefore terrorism is never justified in practice, not only on deontological grounds but also on consequentialist ones.

Within the framework of any legal system, acts of terrorism are legally unjustifiable and obviously criminal. The reasons for it could vary, from democratic regimes that are interested in human rights as part of respect for human dignity to nondemocratic regimes that are interested in power and stability. The criminal nature of acts of terrorism remains the same.

Some religions, such as Jainism, and some denominations, such as the Quakers, Amish, and Mennonites, are pacifist. Others have at least some pacifist inclination. From the traditional religious point of view, the practice of terrorism is always utterly wrong. From the point of view of other religions and denominations, the practice of domestic

terrorism is sinful and forbidden. However, movements within religious frameworks, even if usually marginal, have resorted to the practice of terrorism.

Meaning

Historical examples of terrorism manifested the unscrupulous pursuit of collective goals, which involved inflicting death and injury on numerous people. Under these historical circumstances, causing death was naturally regarded as the extreme form of harming people. The prospects of the victims being considered martyrs or even beatified did not give rise to compelling arguments against usage of the practice of terrorism. A person will never be grateful to enemies for rendering a child, spouse, sibling, or compatriot as a martyr now residing in paradise. This insight into the core of human attitudes toward the death of beloved ones was shared by all parties to the same conflict.

The phenomenon of suicide bombers involves another attitude toward death of the beloved. Many agents of the practice of this form of terrorism left behind records that implied a distinction between a culture that abhors death and a culture that does not. Some relatives of these agents expressed pride and admiration for their acts. However, praising the suicide bombers has never eliminated grieving their death and employing the common practices of mourning and bereavement. The alleged cultural distinction has not been convincingly shown to exist.

Examples

India

The ethnic, religious, linguistic, and political differences between populations within the Indian subcontinent have given rise to a variety of conflicts. Two major foci of conflict involved resort to the practice of terrorism: Kashmir and Punjab. The conflict related to the former reflects certain Hindu-Muslim relationships, while the conflict related to the latter reflects aspects of the Hindu-Sikh relationships.

The two cases involve the pursuit of political changes of different kinds. Groups that used the practice of terrorism in the context of Kashmir, such as Jamma, pursue politically extreme goals of independence or even union with Pakistan. While some Sikh groups that resorted to the practice of terrorism, such as Dashmesh, have acted in pursuit of an independent Sikh Khalistan, other groups hoped to achieve politically enforceable, religiously motivated arrangements with respect to the Sikh temples and a ban on the sale of liquor and tobacco. Whereas the latter pursuit has had some successful results, the former one has not become closer to any acceptable solution.

Ireland

Centuries of conflict over Northern Ireland manifested numerous usages of the practice of terrorism on grounds of national, religious, historical, and linguistic differences. On the Irish Catholic side of the border, Sinn Fein, a political party that had a military branch known since 1924 as the Irish Republican Army (IRA), used the practice of terrorism in Northern Ireland. In 1969, a split took place, and the Provisional IRA (PIRA) was created. The PIRA was involved in many acts of terrorism and assassination. On the Protestant side of the border, the Ulster Volunteer Force, active since 1912, committed acts of terrorism in public places related to the IRA and its supporters.

The case of Northern Ireland is of particular interest because in the late 1990s it reached stages of ceasefire, of cessation of terrorism and guerrilla activities, and even of a political agreement that would lead to lasting peace. However, small groups that might resort to the practice of terrorism still exist on both sides of the border.

Terrorism, International

International terrorism is the phenomenon of extremely violent activities against a population for political or religious purposes that are not related to a specific domestic conflict in particular, but rather to some struggle of a global nature. In this entry, the definition, significance, and justification of international terrorism are discussed and measures that have been taken against it are presented.

Definition

The notion of international terrorism is used in two different senses. In a narrow sense, international terrorism is a special form of domestic terrorism. Consider the following elements of terrorism in general:

- It is a practice of violence.
- The practice involves acts of killing and injuring people who do not jeopardize the life or health of the agents of the practice, as well as threats to perform such acts.
- The practice is used against members of a certain population.
- The practice is used in a regular manner.
- The practice is used in order to terrorize that population.
- The practice is used in order to change the political situation by means of terrorizing the population.
- The practice is used on political, ideological, or religious grounds that justify it in the eyes of its agents.

In domestic terrorism, the purpose of the practice of violence is to change the political situation of a certain state. The means of terrorizing the population of that state are by the killing or injuring of members of that population. Thus, the purpose, the terrorized population, and the victims are all of a domestic nature. However, sometimes one or more of these domestic elements take a form that extends beyond the confines of a single state and population. Activities of terrorism can be related to a region that overlaps a number of states. Attempts to terrorize the population of a nation-state can involve killing people of the same nation but not of the same state. Such activities are often described as cases of transnational terrorism.

International terrorism in the broad sense is not a special form of domestic terrorism, but rather a different kind of terrorism. The purpose of resorting to the practice of violence is not related to any state or some adjacent states in particular, but is global in nature. The intended targets of terrorism are not those of a certain state or nation, but are of a much broader nature, such as members of a certain civilization. Consequently, the intended victims are also members of a broadly and vaguely delineated group of people. In the following text, international terrorism in the broad sense of the term is discussed.

Significance

The phenomenon of international terrorism has changed the role of death in the life of numerous people in numerous areas on the globe in two fundamental ways. First, the constant state of personal insecurity has become widespread. Given ideal conditions of eternal peace, no human being's life is constantly under jeopardy. In ordinary conditions that do not involve terrorism of any kind, most human beings are members of groups that are immune from military or similar enemy attacks. Under conditions of domestic terrorism, human beings who are not involved in the domestic conflict and reside away from the territory of the conflict usually do not have to face daily insecurity. However, when conditions of international terrorism obtain, human beings who do not consider themselves parties to any global conflict, because they are not responsible in any significant way for what caused the conflict or what has happened or is about to happen within its global framework, are constantly jeopardized.

The resulting sense of personal insecurity is deepened by the random element of many activities of terrorism. When a suicide/homicide bomber explodes in a mall, nothing in his or her planned

action need be related to the particular time, place, or dozens of victims. Any other time, place, and dozens of victims would be of the same value, from the point of view of the terrorist. Randomness enhances insecurity.

Second, some ideological and religious grounds on which activities of international terrorism are justified in the eyes of their perpetrators have undergone processes of privatization. Following Sayyid Qutb, the intellectual father of Muslim radicalism, Abdullah Azzam, the teacher of Osama bin Laden, preached global jihad in which Muslims shoulder individual responsibility for defending the community of Muslims from its enemies. A slogan ascribed to him is "Jihad and rifle alone." Thus, according to Azzam's view, it was a personal duty of a Muslim to struggle against the presence of the Soviet Union in Afghanistan. Although just a small minority of the Muslims have adopted, let alone practiced, Azzam's way, an atmosphere that nurtures individual acts of terrorism, of spreading death anytime, anywhere, indiscriminately, has become more than a mere theological possibility.

Justification

Actions of terrorism, whether domestic, transnational, or international, are generally regarded as illegitimate, from any moral, ethical, or legal point of view. Even those philosophical theories that set conditions under which some action of terrorism is considered justified have no practical consequence because the conditions they set are never obtained.

In public and political discourses, which usually do not excel in philosophical subtlety or moral, ethical, and legal responsibility, the most prevalent justification of some forms of terrorism is the slogan "one person's terrorist is another person's freedom fighter." Common usages of that slogan are meant to exempt an agent of a terrorist act from moral responsibility for having committed an atrocity on grounds of the terrorist's attempted justification of the atrocity in terms of his or her doing it as a freedom fighter.

Such an exemption of the agent of an act of terrorism from being morally blamed for having committed an atrocity is never warranted. Freedom fighting, in the ordinary sense of the term, is related to domestic or transnational conflicts, not to global conflicts of an ideological or religious nature. Hence, generally speaking, international terrorism cannot be justified on grounds of its being a strategy of freedom fighting.

More importantly, assuming that international terrorism is on a par with domestic terrorism and transnational terrorism being directly related to some form of freedom fighting, it would still not follow that such acts are thereby, and for that reason, exempt from moral or ethical evaluation or blame.

Underlying the slogan are three conceptual mistakes. First, it rests on a confusion of end evaluation and means evaluation. Acts of terrorism are means. Theoretically, they can be used in pursuit of different ends, both evil ones and good ones. Moral condemnations of terrorism are evaluations of the means people use in pursuit of their ends, independent of the nature of these ends, which are going to be separately evaluated from a moral point of view. Actions of terrorism should never be carried out, never be used as means in a pursuit of any end whatsoever.

An objection can be raised here against the insistence on moral evaluation of the means independent of any moral evaluation of the ends. Are not rational beings required to use means that are effective, that is, means that enable the achievement of the goals, either fully or at least to the best extent possible under the circumstances?

Here is where the second conceptual mistake is made. Although evaluations of instrumental rationality have to do with ends and means relationships, moral evaluations of actions can be made independently of the ends agents had in mind when these actions were planned or carried out. Actions of violence against children as such are always evil. One does not have to be informed about the point of such violence in order to evaluate it from a moral point of view.

At this point yet another objection can be raised. Why shouldn't there be a distinction between ordinary ends and supreme ones, where the latter but not the former sanctify, so to speak, ends used in its pursuit? On the background of such a general distinction, freedom fighting will be naturally regarded as a supreme end that justifies every action performed in its service, including actions of terrorism. However, such a line of argument runs afoul of basic moral intuitions. Would the supreme end of freedom justify genocide? No moral theory would answer this question in the affirmative.

Protection of human life and dignity in general is also a supreme end, and there is no reason to assume that the supreme ends allegedly served by actions of terrorism are more important.

Fighting Terrorism

Three methods of opposing terrorism have been used in the struggle against international terrorism. The end of all of them has been self-defense in the deepest sense of not only preventing activities of international terrorism but also eliminating its threat.

The first method involves intelligence, military, police, and similar activities. To a large extent, international terrorism rests on networks of groups that carry out related actions. Such networks have crucial elements that should be destroyed or significantly weakened in order to preempt imminent activities and prevent possible future activities of international terrorism. The military operations of the United States and NATO against the Taliban in Afghanistan after the al-Qaeda terrorist actions of September 11, 2001, are the most conspicuous application of the first method.

Casualties abound in such military operations, among the troops, noncombatants who reside near the terrorists (collateral damage), and the terrorists. All of them are additional victims of international terrorism.

Activities of home security often involve restrictions on the extent to which citizens may exercise their civil liberties and human rights. Flight security, as manifest in airports, is an example. These restrictions introduce the struggle against international terrorism into daily routine, thereby introducing the idea of death threats into spheres of ordinary life.

The second method of opposing terrorism is that of international law. International conventions on terrorism have been signed and ratified since 1973 (when a UN Convention on the Prevention and Punishment of Crimes against Internationally Protected Persons, including Diplomatic Agents, was adopted by the General Assembly). Introduction of additional conventions took place most intensively during the late 1990s, within the framework of the United Nations, Council of Europe, Organization of American States, Organization of African Unity, and others. Each of the conventions was directed against a certain aspect of terrorism.

Most recent is the UN International Convention for the Suppression of Acts of Nuclear Terrorism, which took place in New York on April 13, 2005. Article 6 of the convention typically requires that each state party adopt appropriate measures "to ensure that criminal acts . . . in particular where they are intended or calculated to provoke a state of terror in the general public or in a group of persons or particular persons, are under no circumstances justifiable by considerations of a political, philosophical, ideological, racial, ethnic, religious or other similar nature and are punished by penalties consistent with their grave nature."

The third method is much less organized but not of the least importance. An activity within the framework of the third method takes the form of educational and other public activities, carried out by people who share with agents of international terrorism their religion or denomination, language, or parts of a culture, and even kinship relationships, but nevertheless oppose international terrorism, both in general and with respect to particular terrorist actions. It may be assumed that the third method provides the best means for a long-range uprooting of international terrorism.

Terror Management Theory

Terror management theory (TMT) is a prominent theory in social psychology that holds the idea that basic motivation for human cognition and behavior is the fear of death. Based on Ernest Becker's ideas regarding human motivation, TMT was generated and published in the late 1980s by Jeff Greenberg, Tom Pyszczynski, and Sheldon Solomon, and centers around the psychological mechanisms typically used to buffer the anxiety deriving from the awareness of one's own death. The authors assert that in order to avoid the feelings of helplessness and terror aroused by the knowledge of the inevitability of death, human beings have developed psychological mechanisms that help eliminate such thoughts from their consciousness. These symbolic defenses are conceptualized as a dual-process model of proximal and distal defenses, whereby proximal defenses consist of attempts to suppress thoughts of death, while distal defenses address the issue of death in a symbolic manner by modifying perceptions of the self and the world.

Most of the empirical work on TMT thus far has focused on two types of distal defenses. The first is based on validating one's *cultural worldview,* thereby providing a set of standards for values and behavior, as well as the promise of transcending death. The second is intended to increase *self-esteem* by living up to the standards prescribed by the culture. In other words, people are motivated to maintain faith in their cultural worldviews and satisfy the standards associated with these worldviews.

Accordingly, TMT has given rise to the *mortality salience hypothesis,* which holds that individuals exposed to reminders of death react positively to ideas and people that support and validate their cultural worldview, and they react negatively to ideas and people that deviate from it. Similarly, mortality salience is expected to lead to cognitive and behavioral efforts toward maintaining or enhancing self-esteem. This hypothesis has received extensive empirical support. In most studies, mortality salience is manipulated by using two open-ended questions: "Please briefly describe the emotions that the thought of your own death arouses in you" and "Jot down, as specifically as you can, what you think will happen to you as you physically die." Other mortality salience manipulations have included proximity to a cemetery, films evoking thoughts of death, death anxiety scales, and exposure to subliminal primes of death-related words.

Research has shown that mortality salience leads people to oppose and even act aggressively toward others on the basis of political, religious, national, moral, and ideological differences, as well as to commend those who uphold their cultural values, such as turning a criminal in to the police. After exposure to a mortality salience induction, participants are also more willing to donate to charity, particularly charities that benefit their ingroup, indicate higher motivation to enlist in the army, and even show a tendency to sit closer to an ingroup than an outgroup member.

Moreover, several studies have found that awareness of death evokes a diverse set of both adaptive and maladaptive responses through which individuals seek to protect themselves from conscious and unconscious death-related cognition. Hence, some studies have found that in order to preserve or validate their self-esteem following a mortality salience induction, participants show higher intentions of keeping fit and other manifestations of positive health behavior, while other studies report a greater willingness to take risks, such driving recklessly and engaging in unsafe sex, along with the denial of vulnerability to health risks. The reactions were most often found to relate to the degree of the relevance of each behavior to the individual's self-esteem.

Another hypothesis deriving from TMT is *self-esteem as anxiety buffer,* which proposes that if self-esteem serves to buffer anxiety, then high self-esteem (either as a dispositional trait or following an experimental manipulation) should reduce the anxiety aroused by real or symbolic threats. Empirical evidence supports this hypothesis, indicating that momentary elevation of the sense of self-esteem or a dispositional tendency for higher self-esteem reduces both physiological arousal and self-reported anxiety in response to a variety of threats.

It has recently been suggested that close relationships may also serve the terror management function of buffering the fear of death. A series of studies has shown death reminders lead to a higher desire for intimacy in romantic relationships,

greater willingness to initiate social interactions, lower rejection sensitivity, and more positive appraisals of interpersonal competence. These effects were found mainly among individuals characterized as high in attachment security, which is considered an emotional regulation device. Moreover, thoughts about sustained or irreversible separation from a close partner led to a higher accessibility of death-related thoughts than thoughts about other kinds of separation, particularly among people scoring high on attachment anxiety. These studies suggest that a mortality salience induction might prompt people to seek proximity in a wide range of interpersonal situations, while thoughts of long-term separation issues might elicit more death-related thoughts.

Empirical work on TMT is continuing. Recent studies have produced evidence of the effect of exposure to awareness of death on various aspects of life, including maternal separation anxiety, breast-feeding, decision making, psychopathology, religiousness and spirituality, and coping with terrorism.

THANATOLOGY

The *Oxford English Dictionary* defines thanatology as "the scientific study of death, its causes and phenomena." Also (U.S. origin), "the study of the effects of approaching death and of the needs of the terminally ill and their families." The word thanatology first appeared in 1842 in a British medical lexicon. By the mid-1970s, thanatology was recognized as a special area of study, and Lawrence Stone referred to thanatology in a 1977 book review of *Growing Old in America* as a special branch of learning exemplified by historians of death, like Philippe Aries and Michel Vovelle, who have promoted the topic.

Background for the Concept: A Multidisciplinary Approach

A pioneer within this special branch of learning was Herman Feifel, whose books created an opening for scholarly discussions and reflections on topics such as death anxiety, terminal illness, hospice and palliative care, and the impact of death on survivors. Another pioneer was Elisabeth Kübler-Ross, whose work with terminally ill people in a Chicago hospital led her to advocate that these patients be seen as human beings deserving dignity. Kübler-Ross created a framework called stages of dying for understanding emotional responses of the terminally ill. Although empirical research has not confirmed Kübler-Ross's stages of dying and clinicians have expressed deep skepticism of the applicability of her ideas, the popularity of her views has not diminished.

While Feifel and Kübler-Ross were pioneers in the psychological aspects of thanatology, other pioneers have shaped our contemporary experiences and understanding of death, dying, and bereavement. In the sociological arena, important contributions were made during the 1960s by psychiatrist Edwin Shneidman, whose work increased the awareness of the complexity of suicide, while Barney Glaser's and Anselm Strauss's qualitative research into responses to death within hospitals gave us new concepts, such as modes of awareness of dying and dying trajectories. In the mid-1960s, sociologist Robert Fulton examined the linkages between death and identity. Then, in the early

1970s, Ernest Becker wrote his influential book, *The Denial of Death*. And in the first years of the 21st century, the Center for the Advancement of Health convened an interdisciplinary group of thanatology scholars who produced a lengthy article that examined research on bereavement and grief and an article examining efforts to bridge the gap separating thanatology practitioners and researchers.

Education about thanatology burgeoned in the 1970s and continued thereafter, leading to two historical interpretations in 1977 and 1986, a 2004 analysis of 30 years of death education in the schools, and a 2007 examination of the state of thanatological education. In 1970, Robert Kastenbaum founded the journal *Omega*. Other peer-reviewed journals followed: *Death Studies* (originally *Death Education*) in 1977, *Journal of Palliative Care* in 1985, *Illness, Crisis, and Loss* in 1991, and *Mortality* in 1996. Since the 1970s, colleges and universities established courses on death, dying, and bereavement, textbooks on these topics were published, and far-right ideologues initiated a backlash against death education.

Hospice and Palliative Care

Perhaps the most profound influence upon thanatology in the 20th century was the growth of the hospice movement and of palliative medicine. Two figures prominent in this medical advance were Cicely Saunders, the founder of the modern hospice movement, and Balfour Mount, a Canadian physician who championed the practice of palliative medicine with people whose terminal illness was beyond treatment. In consort with Kübler-Ross's dogged perseverance on treating dying patients as persons, their insistence that the dying individual is a living human person who deserves respect and dignity has become the credo in thanatology.

Because dying and bereavement affect people physically, emotionally, cognitively, socially, behaviorally, and spiritually, thanatological care requires the coordinated efforts of interdisciplinary teams. Empirical research with both the dying and with the bereaved confirms this holistic aspect to thanatology. Interdisciplinary teams are available to address the multiple forms pain takes: somatic pain, whether acute (e.g., a toothache) or chronic (e.g., the endemic pain of bone cancer); emotional pain (fear about dying alone); behavioral pain (such as regrets at loss of normal activities due to the disabling effects of a disease); cognitive pain (e.g., distress at increasingly failing memory and problems concentrating); social pain (e.g., loneliness at isolation from friends and family); and spiritual pain (anxiety at having been abandoned by God, inability to find any meaning in one's predicament, and personal insignificance in the vast universe).

The Crucial Influence of a Professional Organization

The Association for Death Education and Counseling (ADEC), an interdisciplinary organization in the areas of death, dying, and bereavement, titles itself The Thanatology Association. The ADEC's influence on thanatological research and practice includes many examples. For instance, it has developed and administers a three-hour exam to certify mastery of knowledge deemed fundamental to thanatology. The ADEC sponsors symposia at annual conferences on research that matters to practitioners, offers continuing education on many topics, hosts special interest groups on such subjects as AIDS education and bridging research and practice, and has developed a database to enable people to locate and contact a thanatologist.

Operationalizing Concepts That Serve as the Basis for Study

The ADEC has addressed the complexity and scope of thanatology by identifying six categories fundamental to thanatology research and study by offering operational definitions for each of these categories, thereby giving structure and organization to this growing and influential area of analysis.

1. *Dying:* the physical, psychosocial, and spiritual experience of facing death, living with terminal illness, and caring for the terminally ill.
2. *End-of-life decision making:* the aspects of life-threatening illness/terminal illness that involve choices and decisions about actions to be taken, for individuals, families, and professional caregivers.

3. *Loss, grief, and mourning:* the physical, behavioral, cognitive, and social experience of and reactions to loss, the grief process, and practices surrounding grief and commemoration.
4. *Assessment and intervention:* information gathered, decisions that are made, and actions that are taken by professional caregivers to determine and provide for the needs of the dying, their loved ones, and the bereaved.
5. *Traumatic death:* sudden, violent, inflicted and/or intentional death, shocking encounters with death.
6. *Death education:* formal and informal methods for acquiring and disseminating knowledge about death, dying, and bereavement.

The ADEC recognizes that each of the six thanatological categories is embedded in structural features termed "indicators." Ten indicators have been identified to date:

1. *Cultural/socialization,* which refers to the impact on death and bereavement of culture and socialization (including ethnicity). An example is the influence of ethnic group membership on advance care planning in end-of-life decision making. Another example is social inhibitors to health care.
2. *Religious/spiritual,* which refers to the interactive relationship between belief systems (including spirituality) on reactions to and coping with death and bereavement. An example is how religious and spiritual belief systems understand the place of suffering and views on a life after death. Another example is curriculum aimed at training clergy in matters of death, dying, and bereavement.
3. *Historical,* which refers to changes over time and context that influence how people experience and understand death and bereavement, as well as theories pre-1980 informing scholars about these matters. An example is the scholarly work of Phillip Aries that identified dominant patterns in the Western world toward death. Another example is the earlier scholarship of Sigmund Freud regarding coping with bereavement.
4. *Contemporary,* which refers to post-1980 theoretical viewpoints in thanatology as well as influences on these viewpoints. An example is the emergence of attention toward complicated grief, now referred to as prolonged grief disorder. Another example is scholarship on continuing bonds.
5. *Life span,* which refers to changes over the life span from infancy through old age that involve death, dying, and bereavement. An example is attention to influences on suicide as people change over time. Another example is developmentally appropriate language when discussing thanatology topics with children.
6. *Larger systems,* which refers to systemic influences in society that affect how individuals and families experience death, dying, and bereavement. An example is the growth and development of the biomedical model; another example is the emergence of support groups for bereaved parents.
7. *Family and individual,* which refers to encounters with death, dying, and bereavement from the vantage point of the person and of "the group of people with a relational bond and long term commitment who define themselves as 'family'" (Balk, Wogrin, Thornton, & Meagher, 2007, p. ix). Caregiver issues and gender issues in care of the dying provide examples.
8. *Resources,* which refers to materials and other sources of information that aid in acquiring knowledge about thanatology matters. Books written to help children understand death, dying, and grief serve as one example, as do major national organizations, such as Mothers against Drunk Driving (MADD) and ADEC.
9. *Ethical/legal,* which stands for principles for determining right from wrong in matters of death, dying, and bereavement, as well as laws established that pertain to death, dying, and bereavement. Examples include criteria for the determination of death and workplace bereavement policies.
10. *Professional issues,* which refers to features influencing the preparation, skills, and responsibilities of professionals facing thanatology situations. An example is certification of knowledge and training about bereavement. Another example is recognizing the differences between grief counseling and grief therapy.

Conclusion

In contemporary conversations occasionally one hears dissatisfaction with the term *thanatology.* The dissatisfaction centers on the term's complexity and on its unfamiliarity to many people. No single other term is offered as an alternative, but rather suggestions are for a phrase such as "death, dying, and bereavement." Responses in favor of the term *thanatology* include (a) the term concisely expresses the scope and breadth of the field; (b) the term known across several disciplines; (c) ADEC, the major professional association in the field, has chosen the term *thanatology* to declare its focus; and (d) many complex and initially unfamiliar terms, particularly in biomedicine, identify fields of endeavor. Examples include oncology, ophthalmology, and endocrinology.

In 1977, Vanderlyn Pine maintained that thanatology had gone through three temporal changes: an era of exploration (1928–1957), a decade of development (1958–1967), and a period of popularity (1968–1977). In 1986, he examined 1976 through 1985, which he deemed thanatology's age of maturity. Since 1985 so many occurrences have shaped thanatology that in hindsight it seems premature to consider that the field reached maturity by 1985. The emergent voice of the ADEC, the convergence of practitioners and researchers to bridge the gap separating them, the merger of neuroscience and bereavement research, and the top-notch work in palliative medicine and in bereavement research published since 1985 suggest the age of maturity was a prelude to increased vigor.

Numerous issues capture the imagination of thanatologists and are directing the current and future work in the field. By definition, issues both engage people and lead them to disagree. Advances occur in the creative dynamics of dealing with issues dividing a field. Consider these issues that engage and divide thanatologists, (a) the human person's autonomy implies the right to die with dignity even if that means suicide or euthanasia, (b) grief counseling efforts sometimes benefit the normally bereaved but often harm them, (c) complicated bereavement merits its own psychiatric diagnosis, (d) continuing bonds is both the typical and expected response when coping with the death of a loved one, and (e) people never recover from bereavement.

Tibetan Book of Living and Dying, The

Sogyal Rinpoche's 1992 publication, *The Tibetan Book of Living and Dying,* is a work partly based upon the Tibetan Buddhist text *Bardo Thödol,* or *Tibetan Book of the Dead.* Sogyal Rinpoche's text interprets and expands upon many of the teachings in the *Bardo Thödol* and includes personal stories of struggles with death, dying, and grief in the 20th century. This entry overviews the book's content.

Content

The four main parts, "Living," "Dying," "Death and Rebirth," and a "Conclusion," of the 425-page

book explain Sogyal Rinpoche's interpretations of the *Bardo Thödol* and offer advice in the style of many popular psychology works on coping with caregiving, death, and the dying process. Details of translations from the *Bardo Thödol* are not provided in *The Tibetan Book of Living and Dying*. Sogyal Rinpoche explains basic assumptions within the Buddhist view of reality, including karma, rebirth, the impermanence of all things, and meditation as a means to liberation from the repeated cycle of rebirth and death. Particularly Tibetan Buddhist beliefs are also explained, including the concept of *bardol* (or in-between states) experienced immediately after the time of death, between one life and rebirth in the next. Each of the book's parts is punctuated with accounts of individuals struggling with terminal diseases, grief, or suffering in general. Sogyal Rinpoche often draws parallels between Buddhist and Christian concepts, such as compassion, patience, and the Buddha and Jesus as great teachers, suggesting that the book is meant primarily for Western audiences. Sogyal Rinpoche also draws upon Western poets such as Rainer Maria Rilke, William Blake, and Percy Bysshe Shelley to further establish commonalities between Buddhist and Western epistemologies and modes of contemplation, as well as contemporary scholars and authors such as Elisabeth Kübler-Ross and Cicely Saunders for foundational theories of grieving processes and caregiving advice. A portion of the book's Part Three on "Death and Rebirth" interprets near death experiences (NDEs) in Buddhist terms, referencing the *Bardo Thödol* in detail to argue that NDEs are accepted in the Tibetan Buddhist worldview as valid accounts of what happens in *bardo* existences. *The Tibetan Book of Living and Dying* also contains four appendices, "My Teachers," "Questions About Death," "Two Stories," and "Two Mantras." These sections address contemporary questions about Buddhist attitudes toward such issues as suicide, abortion, and organ donation; provide further personal stories, such as those of an English cancer patient and an American man with AIDS coping with pain; and offer meditative prescriptions for the dying or grieving.

The 1992 publication begins with a brief Foreword by Tenzin Gyatso, His Holiness the 14th Dalai Lama, who emphasizes the importance of a meditative and virtuous state of mind for a good life and a good death, both defined as opportunities for enlightenment.

Bardo Existences

The Tibetan Book of Living and Dying is partly based on the *Bardo Thödol,* perhaps best translated as "Liberation Through Hearing," a reference to the opportunities presented in the bardo stages for liberation from *samsara,* the world of birth, death, and rebirth. The text is popularly known in English as the *Tibetan Book of the Dead.* The Tibetan Buddhist sacred scripture is attributed to Padmasambhava, the 8th-century yogin, and contains deeply rich symbolism often characteristic of the Vajrayāna school of Buddhism. It teaches, in agreement with all Buddhist schools, that there is no self or soul, and desires attached to the imagined self must be overcome in order to achieve release from endless rebirths. According to the *Bardo Thödol,* the period of 49 days, divided into three states or stages, from the moment of death and after is a time in which the deceased will either find liberation or reenter samsara. The words of the *Bardo Thödol* are both explicit instruction and comfort through this passage. In the *Chikhai Bardo* (or "moment of death" state), consciousness separates from the body. In the *Chönyid Bardo* (or state of experiencing "supreme reality"), powerful visions caused by one's own illusions of ego appear. The person must conquer the projected images as representations of his or her own desires. Finally, in the *Sidpa Bardo* (or "becoming" state), the person is drawn to samsara, and the chances for liberation are greatly decreased. The deceased is "becoming" again and searches for a body. It is these three stages of existence that form the basis for Sogyal Rinpoche's discussions and commentaries on death, dying, and the ideal life.

Tobacco Use

Tobacco is a legal product that kills 1,200 people each day, and ultimately half of its long-term users. It contains more than 5,000 toxins and chemicals, including more than 60 cancer-causing chemicals. This product is also highly addictive, making it difficult for users to quit. Despite its lethality, this product is unregulated, widely marketed, and readily available. This entry outlines the myriad of diseases caused by tobacco and provides a review of interventions that could eliminate these preventable deaths.

Trends in Tobacco Use

Adult smoking prevalence in the United States decreased from 42% in 1965 to 21% in 2004. Progress then slowed, and prevalence remained at 21% from 2004 to 2006. In 2006, 45 million Americans smoked. Prevalence was higher for men (24%) than for women (18%) and higher among those 18 to 44 years of age (24%). Smoking prevalence was 10% among Asians, 15% among Hispanics, 22% among whites, 23% among blacks, and 32% among American Indians and Alaska Natives. Smoking was highest among people with 9 to 11 years of education (35%) and lowest for people with 16 or more years of education (<10%). Smoking prevalence was also higher for people living below the poverty level (31%) than for those living above that level (20%). Despite these differences, however, the demographics of smokers still largely reflects the demographics of the U.S. population (white, 12 or more years of education, and half living at >2.5 times the poverty level).

Death by Tobacco Use

Tobacco use is the leading preventable cause of death in the United States. Cigarette smoking causes more than 400,000 deaths each year, which is 18% of all deaths in the United States. Half of all smokers' deaths occur in middle age, and people who die from smoking lose, on average, 14 years of life. Each year, smoking costs $96 billion in health care costs, $97 billion in productivity losses from premature deaths (but excluding productivity costs due to illness), and $10 billion in health care costs and productivity losses from exposure to secondhand smoke. The cost burden to the smoker and his or her family, as well as the costs to society, totals $220,000 for male smokers and $106,000 for female smokers, the equivalent of $40 per pack of cigarettes.

Death From Cancer

Cigarette smoking causes many cancers, including cancers of the lip, mouth, pharynx, esophagus, stomach, pancreas, larynx, trachea, lung, cervix, kidney, bladder, and acute myeloid leukemia. Cigar smoking causes cancer of the mouth, esophagus, larynx, and lung, and may increase the risk of pancreatic, bladder, and colon cancer. Pipe smoking causes lip cancer and is also associated with cancers of the mouth, pharynx, larynx, esophagus, and lung; and there may also be an increased risk of colon, rectal, pancreas, and bladder cancer. Secondhand smoke (SHS) causes lung cancer. Smokeless tobacco causes oral and pancreatic cancer, and may increase the risk for cancers of the stomach and esophagus.

Tobacco smoke contains nearly 5,000 chemicals, including more than 60 chemicals known to cause cancer. Chemical analysis shows that cancer-causing agents are found at comparable levels in the smoke from pipes, cigars, and cigarettes. More than 50 cancer-causing chemicals have been identified in SHS, which is classified as a known human carcinogen. In fact, many carcinogens are found in even higher concentration in SHS than in mainstream smoke. The levels of cancer-causing agents in smokeless tobacco are often at levels hundreds of times higher than the legal limit for foods and beverages.

Death From Heart Disease

Cigarette smoking causes cardiovascular diseases, including coronary heart disease (CHD), atherosclerosis, abdominal aortic aneurysm, and stroke. Cigar smokers who inhale and pipe smokers are at

increased risk for CHD. Exposure to SHS also causes heart disease. In addition, some studies have reported a higher risk of cardiovascular diseases and other complications, such as hypertension, CHD, stroke, diabetes, hypercholesterolemia, and abnormal lipid levels, with smokeless tobacco use.

Death From Respiratory Diseases

Tobacco smoke injures the airways and the lungs. Smoking causes respiratory problems, including chronic obstructive pulmonary disease (COPD, such as chronic bronchitis and emphysema); pneumonia; early onset and a faster age-related decline in lung function; respiratory symptoms such as cough, phlegm, wheezing, and shortness of breath; and poor asthma control. Cigar and pipe smokers are also at increased risk for COPD. SHS exposure causes reduced lung function, pneumonia, bronchitis, recurrent ear infections, cough, phlegm, wheezing, breathlessness, and more severe asthma attacks.

Pregnancy-Related Complications and Infant Death

Smoking before and during pregnancy causes reduced fertility, fetal death, stillbirth, low birth weight infants, pregnancy complications, and sudden infant death syndrome (SIDS). Exposure to SHS also causes lower birth weight infants and SIDS. Adverse pregnancy outcomes have also been reported from smokeless tobacco use.

Tobacco Addiction

Tobacco is highly addictive. When smoke is inhaled, nicotine is absorbed into the arteries and reaches the brain within 10 seconds. Recent research suggests that addiction may start to occur as early as the first few cigarettes. The nicotine in cigar smoke and smokeless tobacco is easily absorbed through the mouth.

Nicotine causes both stimulant and depressive effects. Stopping tobacco use results in withdrawal symptoms, including craving for nicotine, irritability, frustration, anger, anxiety, difficulty concentrating, restlessness, decreased heart rate, increased appetite, and weight gain. These symptoms begin within 24 hours of quitting and peak within a few days. Most symptoms last only a few weeks, but cravings for tobacco can continue for years. There is also a strong behavioral component to nicotine dependence. For regular smokers in particular, smoking has become so intertwined with usual daily activities that cravings and possible relapse are likely to occur when engaging in these everyday activities.

Ending Tobacco-Related Deaths

Tobacco industry responses to consumer health concerns have included the filter cigarette, reductions in machine-measured average tar and nicotine content, and, more recently, new cigarette and smokeless delivery systems. Because these innovations were perceived as safer, many smokers concerned about health issues switched to such products rather than quit tobacco use entirely. However, studies suggest these innovations provide little or no health benefit.

To end the epidemic of tobacco-related deaths, it is necessary to stop the onset of new tobacco users. However, even if no one started to use tobacco beginning today, it would take 60 to 70 years before all tobacco-related deaths ceased. Stopping tobacco use halves the risk of death from myocardial infarction (MI) within 1 to 2 years and significantly reduces the risk of cancer death within 5 years. Data also suggest that life expectancy is not significantly reduced if cessation occurs before age 35. Thus, it is important to help tobacco users quit as early in life as possible.

Product Regulation

In the United States, the nicotine, toxin, and carcinogen content of tobacco products is unregulated. The Federal Drug Administration (FDA) regulation of tobacco has been recommended by the Institute of Medicine and others. Bills to give the FDA authority to regulate tobacco have been introduced, but have not yet passed.

Stronger warning labels can increase people's understanding of the health risks of tobacco use. To be effective, warning labels need to stand out, have a visual impact, and give specific, rather than general, information. Stronger warning labels in Australia and Canada appear to have had larger effects on quitting behavior than the older labels.

Tobacco Taxes

The most effective intervention to prevent young people from starting to use tobacco and to motivate current users to quit is to increase the price of tobacco products. For every 10% increase in price, youth uptake of tobacco use decreases by 7% and adult use decreases by 4%. Equivalent taxation across tobacco products is needed, or use will just shift to other products.

Coupons and other offers reduce the impact of tax increases. There has been a dramatic increase in tobacco industry spending on these price discounts in recent years, particularly in states that have comprehensive efforts to reduce tobacco use. Other price strategies include restrictions on free tobacco product samples, restrictions on coupons or discounting, prohibiting the sale of single cigarettes, efforts to combat smuggling, and restrictions on Internet or mail-order sales.

Countermarketing Campaigns

Sustained counter-marketing campaigns are important in order to counteract the $13 billion to $15 billion spent each year by the tobacco companies to promote the use of tobacco products. Countermarketing campaigns reduce youth and adult tobacco use by changing social norms about tobacco use, increasing awareness of the health hazards of smoking and exposure to SHS, educating about tobacco industry actions, motivating people to quit, and informing tobacco users about resources available to help them quit. Media has also been shown to be effective in increasing calls to telephone cessation quit lines. Media is also used to generate support for tobacco control efforts, such as smoke-free policies.

Studies suggest that partial bans on tobacco advertising are not effective, but complete bans decrease tobacco consumption. The lack of effect of partial bans may be due to such bans being circumvented. For example, after the broadcast ban went into effect in the United States, tobacco advertising merely shifted to other media—newspapers, magazines, billboards, and the point of sale.

Efforts have been made to reduce tobacco advertising that targets children. Lawsuits against R. J. Reynolds have resulted in the discontinuance of the "Joe Camel" campaign, which targeted children, and the "Kool Mixx" campaign, which allegedly targeted urban minority youth, as well as restrictions on the marketing of candy, fruit, and alcohol flavored cigarettes.

The 1997 master settlement agreement (MSA) between the tobacco companies and the states imposed some restrictions on cigarette marketing in the United States. There could no longer be (a) brand name sponsorship of concerts, team sporting events, or events with a significant youth audience; (b) sponsorship of events in which paid participants were underage; (c) tobacco brand names in stadiums and arenas; (d) cartoon characters in tobacco advertising, packaging, and promotions; (e) payments to promote tobacco products in entertainment settings, such as movies; (f) sale of merchandise with brand name tobacco logos; and (g) transit and outdoor advertising, including billboards.

Prohibiting other retail products from having tobacco images or brands, eliminating images of tobacco use on television and in movies seen by minors, restricting advertising in magazines and other print media with high youth readership, and eliminating candy cigarettes or shredded bubble gum that is packaged to look like smokeless tobacco are other ways to reduce youth exposure to protobacco messages.

Minors' Access Restrictions

Restrictions on minors' ability to purchase tobacco are effective, but only in conjunction with other community interventions and continued enforcement. In 1992, Congress required every state to have a law prohibiting tobacco sales to minors under age 18, to enforce the law, to conduct annual statewide inspections to assess the rate of illegal sales, and to develop a strategy to reduce the illegal sales rate to 20% or less. The average violation rate decreased from 40% in 1997 to 11% in 2006.

The MSA also contained the following youth access restrictions: restricts free samples except where no underage people are present, prohibits gifts to youth in exchange for buying tobacco products, prohibits gifts through the mail without proof of age, and prohibits the sale or distribution of packs smaller than 20 cigarettes.

School-Based Prevention Programs

School-based tobacco prevention programs are effective only when combined with interventions

in the community. Quality school-based prevention programs implement tobacco-free campuses and provide curriculum that highlight the negative social consequences of tobacco use and help youth resist the pressure to use tobacco. Program effects decay without additional educational interventions, media campaigns, or supportive community interventions, and comprehensive approaches are necessary for long-term success.

Smoke-Free Policies

In 2006, the Surgeon General concluded that eliminating smoking in indoor spaces fully protects nonsmokers, but that separating smokers from nonsmokers, cleaning the air, and ventilating buildings cannot eliminate exposure to SHS. Although the purpose of smoke-free policies is to reduce SHS exposure, these policies also reduce cigarette consumption, increase quitting, decrease relapse, and reduce initiation. Smoke-free venues help create nonsmoking social norms and reduce smoking by adult role models. However, tobacco industry promotion of smokeless tobacco "for when you can't smoke" could negate the impact of smoke-free policies on increasing cessation.

After the implementation of smoking bans, studies have shown dramatic declines in the amount of irritants and cancer-causing chemicals in the air and improvements in respiratory symptoms and the lung function in hospitality workers. Several studies have reported decreased heart attack rates in communities after smoke-free policies have been implemented. A recent national study reported that nonsmoking adults' exposure to SHS was only 12% in counties with extensive smoke-free laws, compared with 35% in counties with limited coverage, and 46% in counties with no law.

Cessation Interventions

Brief clinician advice to quit tobacco use increases cessation rates 30% and more intensive counseling doubles the cessation rate. Cessation coaching provides practical advice about how to deal with withdrawal symptoms and the challenges of quitting and provides support to the tobacco user. Currently there are seven FDA-approved medications for treating tobacco use, and these medications double or triple success rates. Using counseling and medication together produces even better results. However, few tobacco users use these treatments. Even those that use treatment often do not use as much of the medications as recommended, which may lower success rates.

Telephone cessation quit lines increase access to treatment because they are free and generally available days, evenings, and weekends; do not require transportation or child care arrangements; and provide individually tailored help. Some quit lines also provide free nicotine replacement therapy. In 2007, all states had telephone cessation quit lines that could be reached though a single phone number, 1-800-QUIT-NOW. However, funding for state quit line services has been erratic. Even when funding is available, it is often insufficient to provide counseling and medication to all tobacco users interested in quitting.

Insurance coverage of tobacco-use treatment increases the use of effective treatments and the number of smokers who successfully quit. These treatments are cost saving, yet tobacco-use treatment is one of the least provided preventive services under both public and private insurance.

Comprehensive Approaches

Putting all the effective strategies together in a comprehensive approach has been proven to decrease the initiation of tobacco use, decrease youth and adult prevalence, and reduce disease. However, comprehensive efforts must be continued to be effective. Sustaining funding for state tobacco control programs has been a continued challenge. Most of the initial state-funded programs sustained significant cuts or were virtually eliminated. In 1998, the MSA provided $246 billion over 25 years to the states to compensate for Medicaid and Medicare costs for treating smokers. Although it was expected that states would fund comprehensive tobacco control programs with the proceeds, in 2007, only three states were funding such programs at the Centers for Disease Control and Prevention (CDC) recommended levels.

In summary, at one time lung cancer was a rare disease. Today, however, lung cancer is the leading cancer killer of both men and women. Eliminating all tobacco use could eventually prevent 80% of COPD deaths, nearly 20% of pneumonia deaths, nearly 60% of all aortic aneurysm deaths, 17% of

ischemic heart disease deaths, and more than 10% of stroke deaths. It could also eventually prevent a large percentage of cancer deaths, including more than 60% of oral cancer deaths, nearly 70% of esophageal cancer deaths, 20% of stomach cancer deaths, nearly 25% of pancreatic cancer deaths, 80% of throat cancer deaths, 12% of cervical cancer deaths, more than 25% of kidney cancer deaths, 17% of bladder cancer deaths, and 17% of the deaths from acute myeloid leukemia. The decrease in cigarette consumption has been termed one of the greatest public health achievements of the 20th century, but progress has stalled since 2002 in youth and since 2004 in adults. The challenge of the 21st century will be to resume and accelerate progress by fully implementing the interventions that have been proven to reduce tobacco use.

Tomb of the Unknowns

Until the recent past, in every war there have been fallen soldiers' bodies whose remains could not be identified. Surely these soldiers were buried by their respective states, but the idea of erecting a monument to these unknown war dead has a relatively recent history. One of the earliest such monuments was an 1866 memorial to those unknown soldiers from the American Civil War.

Following World War I (WWI), the notion of monuments to unknown soldiers became standard for those countries that had participated in that war. In 1920, such a monument was designed when the remains of an unknown soldier from the forces of

the British Empire in WWI were interred in Westminster Abbey. Also in 1920, a memorial to the unknown dead of WWI was placed under the Arc de Triomphe in Paris by the French government.

In the United States on November 11, 1921, an unknown soldier from WWI was placed under a marble slab in the Memorial Amphitheater in Arlington National Cemetery, the last resting place of huge numbers of soldiers and several presidents in the United States. The soldier was buried with full military honors. On November 11, 1932, the completed monument, a white marble sarcophagus, was erected in the Memorial Amphitheater in Arlington National Cemetery, Washington, D.C. The stone for this monument came from Marble, Colorado. The sarcophagus is plain except that on its east panel (facing Washington, D.C.) are three carved figures from ancient Greece representing peace, victory, and valor. On the west panel facing the Memorial are the words: "Here Rests in Honored Glory An American Soldier Known But To God."

On Memorial Day, May 30, 1958, the remains of unknown soldiers from WWII and the Korean War were also placed under marble slabs next to their fallen comrade from WWI. At the time of this ceremony, the name of the monument was officially changed from "Tomb of the Unknown Soldier" to the "Tomb of the Unknowns." An unknown soldier from the Vietnam War was later added to the group. However, in 1998, through DNA testing, these remains were identified and subsequently returned to the family for burial. It has since been decided that no more remains will be buried at this simple, beautiful monument.

In the United States, the Tomb of the Unknowns stands in the center of Arlington National Cemetery, and it is one of the most visited sites in Arlington and, indeed, in the entire Washington, D.C., area. Part of the reason for this interest is related to the ceremony of the changing of the guard. The tomb is guarded continuously, that is, 24 hours per day and 365 days per year no matter what the weather, by elite members of the 3rd United States Infantry—the "Old Guard." This unit has served the United States continuously since 1784 and is the oldest active duty unit in the United States. Only certain members of this unit are chosen for the guard at the Tomb of the Unknowns. The selection process is rigorous as only well-qualified members of the army can be entrusted with the task of providing a continuous honor guard for those who represent all of America's fallen heroes.

Those members of the 3rd United States Infantry who are selected as guards wear no rank insignia on their uniforms so that they will not outrank any of the unknowns, no matter what their rank was. Each "walk" around the tomb is carried out with much ceremony. Walks last for half an hour during the summer months and 1 hour during the winter months. At night, when Arlington National Cemetery is closed, the walks are 2 hours in length. At the end of the walk, the guard is changed—a ceremony that signifies the great honor afforded this nation's war dead. Both the walks and the changing of the guard are solemn military rituals that resonate with symbolism. During the walk, the guard walks south for 21 steps (to signify a 21-gun salute), stops for 21 seconds, and then walks north the 21 steps back. This walk in front of the tomb continues for the entire shift. Naturally, the guard does not talk or acknowledge anything but the honored walk for his or her time at the tomb. The changing of the guard is a formal ceremony in which one guard is brought to the tomb to change places with the guard currently on duty. It would be the rare individual who witnesses the guarding of the tomb or the changing of the guard who was not moved almost to tears by the ceremony.

The Sentinal's Creed taken by all these members of the Old Guard is:

My dedication to this sacred duty
Is total and wholehearted—
In the responsibility bestowed upon me
Never will I falter—
And with dignity and perseverance
My standard will remain perfection.
Through the years of diligence and praise
And the discomfort of the elements
I will walk my tour in humble reverence
The best of my ability.
It is he who commands the respect I protect
His bravery that made us so proud.
Surrounded by well meaning crowds by day,
Alone in the thoughtful peace of night,

This soldier in honored Glory rest
Under my eternal vigilance.

The Tomb of the Unknowns has been guarded continuously with these solemn ceremonies since July 2, 1937. This is a tribute to the respect with which Americans honor those who have fallen in the defense of freedom.

Tombs and Mausoleums

A tomb or mausoleum is defined as a repository for either the cremated ashes of a deceased person, an actual corpse, or coffin. It is the place of interment for multiple bodies built above ground level or separated from earthen material if constructed below ground level. The notions of separation from contact with the actual earth and a physical vault that can be seen, touched, or entered are essential psychological components of these placements of deceased loved ones.

While research into death and dying has developed a broad research base, the focus on tombs and mausoleums is a relatively new area of investigation. Typically the research domain of sociologists, in recent times the concept of death and its relationship to entombment and spaces of death have received an interdisciplinary focus. Investigators from disciplines such as ethnography, social psychology, city planning, and professionals from within the death industry itself have come to see the importance of these physical spaces in regard to the psychology of spatiality and memorialization of the death and dying process as a whole.

In societies that use crypts, burial chambers, or tombs as either one aspect of the postdeath visitation experience or as a final repository after the funeral rites that is never revisited, these burial spaces have several symbolic functions relating to the notion of "permanency." As death and subsequent decomposition of the body represent two of the most primal fears of humanity, the tomb plays an important role in that its functionality and physical presence play a deeper psychological role through an inter-related, three-way process reminding and reassuring those connected to the deceased, and the society at large, of several key facets related to this deep-rooted fear. This process is discussed in the following sections.

The Social-Cultural Functions of Tombs and Mausoleums

Whether housing single or multiple bodies, the tomb is a singular place that represents what has been called the *three spaces of death*. These nested or interrelated spaces are an important facet for both the deceased and the living in the crypt. There are three social-cultural functions that emerge from these spaces of death.

Reestablish the Routines of Life

Whether it is unexpected or at the end of a given time frame, death interrupts the normal ebb and flow of life. This rupture of the everyday process of living commences a process of grieving for the departed that unfolds in a series of stages, each of which are connected by an initial sense of disequilibrium and a profound sense of loss that is manifested both psychologically and physically. For many cultures, entombment in all of its various forms is seen as an integral component of stabilizing the feeling that not only is the deceased a missing physical element of everyday life, but that there is a deep, and often seemingly intangible, psychological sense of having a portion of self taken away.

In the limited research done in this area, respondents report that at the point of death of a loved one, and for some time afterward "it feels like a

part of them has been ripped away," or that "there is a part missing." The physical presence of a tomb acts as an agent of healing this sense of a physical and emotional rift and allows the immediate family and social collective to come to grips with the profound sense of finality associated with their understanding and acceptance of the concept we often term "passing away."

Just as it is recognized that language reveals the limits of a culture's understanding, so too the tomb is a form of physical language that, in the process of grieving, speaks to a community of limits and finality. In either its position above ground, its situation that all have to look up to see, or by its physical presence, the sepulcher, crypt, or mausoleum has a multilayered voice that signifies all living beings have a final point of life and that life goes on regardless of death. As such, the tomb is a point and place in binary time that acts as a physical segue between the sense of disconnectedness associated with the grieving process and the awareness that life needs to continue on.

In this role as a point of connection and unspoken physical language, the mausoleum and all its variations also function as point of control. It facilitates the gradual control over the grieving process in that the cascading processes of despair, anger, and acceptance can be experienced concretely at these sites, as they concentrate these emotions on a thing that can be seen. Related to this point, they also act as a point of control. One of the critical fears of the human condition is death and its seemingly capricious nature. Thus, the tomb by its very nature and function acts as a point of control in a process and understanding that is seemingly uncontrollable.

Memorialize a Life Lived

While a tomb has a key place in orchestrating control over the final facets of the grieving process by providing a sense of location, another psychological role is that it also imparts a sense of time and permanence by its spatiality. Thus, it becomes a place of memorialization.

The structure itself affords opportunities for two key courses of action in this regard. First, it provides a place of finality or closure in regard to the interconnected elements of the actual death if it was unexpected, the death bed if death takes time, the emotional components of the surrounding loved ones, the ritualized facets of the funeral, the postfuneral social or ritualized events, and the laying to rest of the departed. It is recognized that all societies and cultural groups strive to control death in some way. The tomb reconstructs a sense of hope that life with all its hardships has come to an end, and the one who has died is now at peace or, in a sense, simply asleep. Thus, in many parts of the world, tombs and tombstones are consistently inscribed with this form of language, such as "Rest in Peace," "Laid to Rest," and "Fallen Asleep." Thus, a sense of hope is overlaid onto one of humankind's fundamental fears, the fear that there is nothing after death, or what is commonly called existential angst.

The second aspect of memorialization ritual activity and frameworks of understanding tombs brings into play that not only do they bear the name or signify the place of interment of an individual but they also instigate revisitation. While tombs can be revisited with all of the rituals that are attached to this process, such as the giving and refreshing of flowers in the Western world, tombs can also be revisited as memory. Thus, the family and perhaps society as a whole can have an ongoing relationship with the dead, even through the process of simply idealizing where the dead have been laid to rest. Therefore, the tomb can play an important part as memorialization gives stability to the human condition in that not only do we as a species cling to life at all costs but, in regard to our dead, we have a tendency to want to see them as part of the ongoing living as well. Also, the spatial psychology of the tomb acts as the means by which we can concretize life after death as well. That is, by being able to see a definitive, stable structure, we can not only cope with death in life, but also hope that the same stability exists after death. Thus, in addition to the religious elements that often accompany a tomb, this sense of physicality gives another sense of sacred control. We compress our paucity of understanding the concept of the infinite and the universe into a smaller space, a space where the concepts of death can be dealt with and accepted.

Stabilize Death in the World of the Living

A key facet of death is that it tends to induce a sense of disequilibrium in those closest to the deceased. The human condition is reliant on both

a psychological and actual sense of horizon and of symmetry in order to make sense of the immediate world around them and the universe at large. The tomb or mausoleum provides this stabilizing sense in that it gives dimensions, a plane of horizon and a definitive volume, to a landscape. This stabilization also serves to further add to the memorialization process in that it gives an evaluation of life. In its firmness, this final resting place nonverbally says, here was a life lived and a life remembered. The landscape, symmetry, texture, and dimensions of the tomb give stability within the human concept of the possibility of "nothingness" after death, and the symmetry and horizons it creates give a sense of constancy when death tends to be framed as the unknown.

Another key aspect of the tomb is that it provides tangible evidence, or an impression, that the body is separated from contact with the earth. This sense of solid distance provides psychological comfort to another of humankinds' greatest fears, which is the decomposition of the body after death. While this respect is given to the dead, it is also a part of the well-being of the living. The tomb offers hope that when the living die, they too will be interred in a similar fashion, and while decomposition will occur, the remains will not become an actual part of the ground and, therefore, there will be a semblance of ongoing life.

The tomb is an important aspect of not only death, but also of life in general. It is in many ways a segue between living and dying. In a world that is becoming increasingly characterized by what has been termed *memento mori*, where concepts of death and dying have been removed from everyday existence and become a hidden industry in the industrial first world, the tomb is a constant reminder that not only is death inevitable, but that psychological stability is also grounded in our ability to see death and accept it. While the tomb can be seen as shelter for the dead, it is more importantly a psychological shelter for the living.

Tombstones

A tombstone is a marker for a grave. Historically many graves have gone unmarked, but where tombstones are used, across cultures these markers are made of different materials. There are graves marked by fieldstone that are either placed upright or horizontally on the surface of the earth. Fieldstone can be any type of rock, but it is generally made of local material, such as sandstone. Usually nothing is inscribed on the stone, which serves solely to inform the living that someone is buried below. One example is historic African American slave cemeteries located in the southern portion of the United States that are replete with irregularly shaped fieldstones.

More elaborate tombstones are made of materials such as granite, marble, slate, limestone, iron, and bronze and are often carved with descriptive notations, inscriptions, and are sometimes ornately decorated. Tombstone grave markers are also perishable. Wooden crosses weather and deteriorate over time. Some wooden crosses are plainly carved, while other crosses are carved into hearts or even stylized people. This essay offers a brief history of tombstones and provides a discussion of the functions, uses, and culture of tombstones.

History of Tombstones

Prehistoric groups throughout time marked their graves with a stone or a horizontally placed slab of stone. Neanderthals may have been the first species to mark their graves. At the rock shelter site located at La Ferrassie in France, which dates to 70,000 years ago, paleoanthropologists have found eight buried Neanderthal skeletons. One of these individuals was buried under a triangular stone, thus representing what some analysts believe to be one of the earliest tombstones.

Ancient Egyptians, Greeks, Romans, and Persians at times marked an individual's grave with a stone. In Greek society, for example, the only individuals awarded a tombstone were those Spartan warriors who died in battle and mothers who died in childbirth. But generally tombstones were not considered essential until 1804, when on June 12 of that year, France created the Decree of Prairial, Year XII. This decree established that burials were not to be in churchyards and towns but in cemeteries outside the city, and that common graves would be replaced by juxtaposed graves. Individuals could buy a grave plot for perpetuity. The Decree of Prairial also stated that a tombstone or other burial mark could be placed over the burial site of a loved one. In one cemetery, called Père-Lachaise, 114 tombstones were placed in 1804 and over the period of 1814 through 1830, an average of 1,879 tombstones were placed each year. This decree propelled people to claim a grant of land, big or small, and designate that plot as theirs by a tombstone or monument. To the present time, the tombstone has been integral to a gravesite.

The Social Science and Historical Use of Tombstones

Scholars use historic and modern cemeteries as laboratories for collecting and analyzing data. With a tombstone library of millions, anthropologists and historians, for example, investigate cultural, linguistic, biological, and archaeological data. Each tombstone provides insight into a person's life as marked in stone. Information extracted from tombstones can be used to address broad questions involving biological, economic, social, technological, and religious issues. A single tombstone display may offer numerical, linguistic, biological, epidemiological, geological, iconographic, and epigraphic information.

Sociocultural Characteristics

Rich cultural information can be derived from tombstones. The size of the marker and the material used to create it is indicative of the wealth and status of the individual. A tombstone epitaph may also communicate information about one's low status in life. One such example is found on a tombstone located in Alabama that reads, "E. L. A. Wife of . . . and . . ." (1843–1918) "was pleasant to live with." While the deceased's two husbands are named on her gravestone, the wife is identified by three initials.

Even the method used to engrave the deceased's identification, birth and death dates, and epitaph are suggestive of a person's station in life. The wealth of the deceased can be suggested by the size of and material used to create ornate and elaborate tombstones. The use of a sharp object or a stick to scratch into a hardening cement tombstone versus a stone carved by a stonemason not only speaks to the wealth of the buried but, in the case of the hardening cement, those sentiments and descriptions made by scratches are quick unedited thoughts. Inscriptions carved by a stonemason can be edited and corrected for spelling. Carvers or stonecutters of tombstones also imprint their mark on the front or on the back of the tombstone.

Military veterans are often buried together in a section of a cemetery with each headstone appearing in uniform fashion. But on many of the older tombstones, a written legacy is offered in the form of epitaphs, photo portraits, and engravings. Symbols or a more direct indication of one's occupation also have been listed, thereby providing an indication of one's occupation. Examples include the display of a sheriff's star or a medical caduceus. Other examples are engravings of a semitruck, a trowel, and even an embedded screwdriver in the tombstone, again suggestive of one's occupation.

Language inscriptions and photo portraits as well the documented location of the individuals' city and country of birth are useful for establishing one's ethnicity. Heraldic crests point to a country of origin or ancestry, thereby providing information that is useful to trace migration patterns. Tombstones of Japanese individuals often have

family crests called *mon*. The mon of the Motoyama family is a goose, while the Murata family is indicated by a mulberry leaf.

Symbols of Affiliation

Religious symbols allude to an individual's religious affiliation. Examples of Christian symbolism include carvings of Adam and Eve, a cross (Greek, Latin, Celtic), the chalice, wafer and grapes of the Eucharist, the dove from heaven representing the Holy Ghost, angels, and nails and the crown of thorns representing the Crucifixion. Tombstones with the star of David, the menorah, a Levite pitcher, a yahrzeit candle, or the indication of years according to the Hebrew calendar represent the markers of Jewish individuals.

Over 1,200 symbols and acronyms are recorded on tombstones in the United States alone, representing organizations, clubs, and societies, past and present, to which deceased individuals were members. Examples of these symbols refer to the Masons, Shriners, Boy Scouts, and Woodmen of the World. Familiar acronyms include CSA (Confederate States of America), GVS (Giuseppe Verdi Society), ORC (Order of Railroad Conductors), and NEFMC (New England Fat Men's Club).

Tombstones of males, females, adults, and children often vary in size, shape, and stone material. The male tombstone may be more ornate, larger, or made of marble, while the female tombstone is simple, small, and made of sandstone or granite. An infant's or child's tombstone may be small with carvings, such as a lamb indicating innocence. In the past, the tombstone of an unbaptized infant was often without an inscribed name.

Cause of Death

Demographic information, such as the number, sex, and age, of the deceased are easily obtained from tombstones. If needed, an average age at death can be determined for each decade the cemetery was in use. The same is true for infant and childhood mortality. Such statistics can be used to assist in determining the health of a population or serve to understand the effect of an epidemic, war, or natural catastrophic events.

Older tombstones display epitaphs that indicate the cause of death, such as cholera, yellow fever, flu, drowning, murder, childbirth, explosion, or battle. Multiple tombstones from a family with dates of death on the same day or close together might suggest that death may have resulted from a fire, accident, or an epidemic.

Seriation

A relative dating process called seriation is useful to access the popularity of a style of artifact over time. One examination of the application of seriation involves the change in popularity of designs on New England tombstones. Iconographic representations on tombstones spanning the years of 1720 to 1830 at a cemetery in Stoneham, Massachusetts, were tabulated, the results of which portrayed a pattern involving the use of three popular designs. Each design followed what is known as a battleship curve. First, a design was popular, then became very popular, and then waned in popularity as another design gained in notoriety. From 1700 until about 1760, the death's head design found at the top of the tombstone increased in popularity until its peak in the 1730s through the 1750s, and then decreased in popularity when a new cherub design started to replace the grisly death's head. The cherub is found to be at its greatest popularity in the 1780s, and then it lost favor to a design depicting an urn and willow. The urn and willow increased in popularity throughout the early 1800s.

Humorous Tombstone Epitaphs

Numerous compilations have been made of epitaphs on tombstones. Some epitaphs are humorous as noted in the following:

> Here lies the bones of a man named Zeke,
> Second-fastest draw in Cripple Creek.
> (Boothill; Cripple Creek, Colorado)

Other epitaphs are more poignant:

> My wife from me departed
> And robbed me like a knave;
> Which caused me brokenhearted
> To sink into my grave.
> My children took an active part,

To doom me did contrive;
Which stuck a dagger in my heart
That I could not survive.
(Vermont epitaph)

Or:

His brains were lead; and with the dead he lies;
He said but little, and that little dies.
(Epitaph of a hospital patient; 1662, England)

Historical Preservation Efforts

Tombstones represent an important cultural artifact and record of the past and for this reason organizations such as the Association for Gravestone Studies seek to preserve and record information from grave markers throughout the United States. As other methods of body disposal gain popularity, such as cremation, these efforts are increasingly important. Although such organizations focus on the tombstones of the past, contemporary cemetery regulations dictate tombstones be flat and low to the ground, primarily to facilitate the perpetual maintenance of a cemetery. Thus, uniformity and practical maintenance issues take precedence over the artistic and verbose tombstones of earlier times. The result is a silencing of a final expression of the self through epitaph voice of the individual buried below the tombstone.

Totemism

The word *totem* comes from the Ojibwa, an Algonkin language from the Great Lakes region of North America. It first appeared in ethnographical literature in 1791 in the memoirs of a fur merchant, John Long, but it remained unnoticed until John MacLennan used it as an analytical category in two papers he published in 1869 and 1870. MacLennan defined totemism as the practice, reported not only in North America but also in Australia, of naming clans and exogamous groups according to an animal or a vegetal species. He showed that this practice was accompanied by the belief in a special, intimate relationship between the members of each clan and their totem, sometimes reinforced by the idea they all descend from it. Members of each clan are thus said to treat their totem with the respect due to an ancestor: they must not kill it if it is an animal, cut it or gather it if it is a plant, and they must not eat it. Animal totems are preponderant among North American tribes. For instance, the main clans of the Ojibwa at the beginning of 20th century were named marten, loon, eagle, salmon, bear, sturgeon, bobcat, lynx, crane, and chicken. Australian totems, however, often include plant names, and also meteorological phenomena (such as wind, hail, or lightening), artifacts (such as anchor, boomerang, or pirogue), and even sometimes terms related to the human body (such as boy, bosom, clitoris, or corpse).

It might seem irrelevant in at least two ways to devote an entry to totemism in this *Encyclopedia of Death and the Human Experience*. Death has been indeed thoroughly absent from the passionate debate on the nature and origin of totemism that has agitated not only anthropology but also philosophy and psychoanalysis from the end of the

19th century to the middle of the 20th century. Moreover, since Claude Lévi-Strauss convincingly revoked totemism as an "illusion" in his famous essay written in 1962, this idea has tended to disappear from the social sciences. However, totemism has been recently revived in anthropological analysis by Philippe Descola, and it seems that death, as a human experience, could hold a significant role in the new understanding of this problematic concept.

The Golden Age of Totemism: Australian Hopes and Disillusions

The two articles by MacLennan initiated a heated debate through which the greatest names in anthropology, among which James George Frazer, Bronislaw Malinowski, Émile Durkheim, and Franz Boas laid the early foundations of the discipline. But the interest in totemism reached out from the limits of anthropology to the whole humanities. The debate involved not only philosophers but also psychoanalysts after Sigmund Freud's celebrated essay *Totem and Taboo* in 1913. All these authors believed that totemism could give insight into the most "primitive" forms of religion, and they rivaled in reconstituting from what could be observed at their time a hypothetical "original" state of human thought, in which culture would hardly be separated from nature.

In 1887, it was James George Frazer who gave the first synthetic account of the available anthropological knowledge on totemism in a small book simply called *Totemism*. He updated this work in 1910, publishing four volumes of the most monumental compilation of data on this topic. By the beginning of 20th century, the focus of the debate had shifted from North America to Australia, thanks to the extensive description by Walter Baldwin Spencer, Francis James Gillen, and Alfred William Howitt of several Aboriginal societies, such as the Aranda of the central desert. Their description of "still active" and more "primitive" totemic systems aroused the hope they would complete the American data, which were sometimes patchy and believed to represent a more "evolved" state of totemic religion. Australian facts, nevertheless, brought more problems than solutions, and while Frazer and Durkheim kept praising the data provided by Australian ethnography as the "purest" form of totemism ever described, they strove to make it fit in a single model together with the knowledge already available.

As was already known through North American facts, it is not only clans and other exogamous groups that can be named according to natural species, but also the sexes—a different animal or plant being attached to men and women of the group—and individuals. Among the Kamilaroi of the Australian east coast, for example, sorcerers are associated with animals and most of all to reptiles: They are believed to host them in their body and sometimes produce a tamed animal to prove their power. But more challenging for the theories of these authors, Australian ethnography showed a great variability in the link between the attribution of totems and the exogamic rule. Indeed, among several of the Aboriginal societies, such as the Aranda described by Spencer and Gillen, totems were not inherited, but attributed to a child according to the place, itself, associated with a particular animal ancestor, where the mother felt the first signs of her pregnancy. Even more surprising, the two ethnographers reported that the interdiction on the killing and the consumption of the totem animal was not an absolute one among the central tribes of Australia. Therefore, rather than reinforcing totemism as a category, Australian ethnography was undermining its two supporting pillars: exogamy and taboo.

Several anthropologists tried to overcome these difficulties by producing theories of origins that would make these heterogeneous facts fit into a single evolutionary scenario. Frazer, notably, explained the loose link between exogamy and totem and the moderate taboo on killing it among the Aranda by a hypothetical original state of totemism, characterized by endogamy and ritual consumption of the totem species.

Claude Lévi-Strauss and the "Totemic Illusion"

In the short pamphlet against totemism he published in 1962, Lévi-Strauss noted that studies on totemism had tended to conflate two different phenomena: first, a general process of identification between particular social groups or individuals and an animal species or a variety of plant; second, a principle of social organization consisting in distinguishing kinship groups with names of natural

species, which is but one among many techniques of group naming. Yet, while these phenomena exist independently in many places, cases where they organically coexist in a single society are more seldom, and it is sometimes doubtful that institutions described as "totemic" really concern both these aspects. Even the Ojibwa case, from which the term originally came, is uncertain, as ethnographers later suggested that in his use of the term totem, John Long confused the practice of clan naming with the belief in animal guardian spirits that were called by something completely different. Could totemism be nothing but a mere misunderstanding?

Lévi-Strauss goes further into denouncing what he calls a "totemic illusion." In his view, totemism is an illusion because it particularizes as a distinct and "primitive" institution what is in fact one of the multiple manifestations of a universal intellectual faculty of world ordering. Lévi-Strauss shows through a convincing demonstration that what has been called totemism is a classificatory device that uses contrasts in the natural world to think and organize significant differences within society. In other words, what matters is not so much the similarity postulated between the group *a* and the species *x,* but the correlated differences between a series of contrasted natural species (*x, y, z*) and a series of contrasted social groups (*a, b, c*). What so-called totemic systems postulate is that there is as much difference between the group *a* and group *b* as between the species *x* and the species *y;* between the group *b* and the group *c* as between the species *y* and *z*; and so forth. Under structuralist analysis, totemism thus evaporates, revealing itself as a mere instance of the universal ability of the human mind to think about the world through contrastive oppositions.

Totemism Resuscitated: Descola and the Ontological Way

Revoking totemism on the basis of its "social organization" dimension, specifically the naming of distinct groups, leaves unresolved the problem of the identification of groups and individuals with animal or vegetal species. Philippe Descola recently proposed to reconsider the problem in an "ontological" perspective. Totemism, as an ontology, is characterized by the idea that humans and nonhumans share what he calls "aggregates of similarities." He grounds this reappraisal of the notion on a comparative account of the terms by which Australian societies describe their own totems. He shows that this totemic terminology describes a series of physical and moral qualities shared by the members of a group and their totem. Thus, among the Australian Kariera, the sections "fast" and "warm-blooded," and the sections "slow" and "cold-blooded" are each associated to a species of kangaroo, one moving quicker than the other; the sections "fast" and "warm-blooded" and "slow" and "cold-blooded" are each associated to a species of goanna, one being more "massive" (and supposedly slower) than the other.

This enables Descola to study in a single perspective many different practices of physical and moral identification between humans and nonhumans. Ethnographers, for instance, have given evocative descriptions of the different hair arrangements by which the Plain Indians of the clans of the Crow, of the Buffalo, and others imitate their totem. To avoid the dissolution of the concept into too vast a category, Descola defines totemism as an ontology that postulates a continuity between humans and nonhumans, both on the plane of physicality (which designate not only the aspect of a given being, but also its characteristic behavior) and on the plane of interiority (mostly the attribution of moral qualities). Totemism thus supposes a close relationship between humans and nonhumans, inasmuch as a human's life can be equated to a plant's or to an animal's life: "The life of a bat is a man's life" is a saying by the Wotjobaluk of Australia, where the bat was the totem for the male class. Furthermore, in many societies, injuring a totem animal was believed to have a direct effect on the very body of the members of the associated group. Also in many cases, the killing of a totem animal was avenged by the members of a clan, and it could be punished by death.

Experiencing Nonhuman Death as a Human One

One of the best illustrations of the quasi-equivalence postulated between the life of the totem and a human life may be that when a totem animal or plant is involuntarily killed or found dead, it is cared for and buried as a clansman. Frazer reported that among the Samoan, when a man of the Owl totem found a dead owl, he would weep over it,

beat his forehead with stones, and then wrap up the bird and bury it as if it had been a human being. Surprisingly, although similar facts have been reported by several authors, death has remained, until now, peripheral to the debate. Yet, following this new understanding of the notion, totemism could eventually be characterized as an ontology in which the death of a natural species, animal or plant, is avenged like a human death, ritually treated like a human death, and thus somehow experienced like the death of one of our own kind.

Transcending Death

One remarkable paradox of existence is that the obvious decay of human bodies after death has frequently been countered by beliefs in immortality. Myths, religious doctrines, and philosophical ideas explaining this possibility reveal the power of meaning making as an integrated process of human thought and feeling. Such afterlife destinies are often shaped by basic ideas of reciprocity fundamental to ordinary social organization but now elaborated into doctrines of merit associated with divine judgment or processes of karma. Rituals regularly frame these ideas and help manage human emotions surrounding them, especially that of hope.

Meaning Making and Survival

Death transcending beliefs, originating in this characteristic drive for meaning, have survival as their goal and express a wish for a better life, unconstrained by the limitation of death. Religiously, they reveal a longing for some paradise or heaven in which evil is overcome and a union with the divine is achieved. The key emotional basis for pursuing such transcendence is that of hope, with acceptance of the beliefs that make it possible lying in the nature of faith and in belief in an ultimate embodied state or in a deity transcendent over all things.

Hope

Hope is as integral to death transcendence as to survival in life itself. It affirms the worthwhileness of existence and looks to future goals that may not be apparent in the present. Hope generates the ongoing success of community life and, in the context of death, depends on being widely shared by a group that is able to sustain individual members who may have, temporarily, lost hope and are in despair. Hope infuses the human imagination when it constructs myths, and religious, philosophical, and political theories about existence and the nature of death. While such a picture of the meaning of life can assume an order of reality that denies the validity of the schemes of other groups, its success depends upon the affinity individuals feel toward them, and this may change over time. As emotional beings, we are encouraged to pattern our feelings in particular ways and to share expressions of our moods. This management of human emotion is a fundamental task of society and has traditionally been undertaken by what we call religion, especially as far as death is concerned. An allied issue is that of morality, the sense of values a society prizes and applauds in its members. This moral aspect is of profound importance for death transcendence because hope is not simply an optimistic energy but is grounded in this moral domain

of commended values, ensuring that hope is given some degree of substance by making it integral to the relationships that constitute human communities. It is this moral value, born of daily reciprocal relationships, that drives religious ideas of death transcendence and the ongoing worth of human existence despite the constraints of death.

Reciprocity, Merit, and Identity

At the foundation of much human life are ideas of reciprocity, of mutual giving and taking and giving again, that build up a society. In traditional sociological terms, such a society is a moral community, and it is the reciprocity that makes a moral community that also serves as the basis for transcending that community and for transcending death itself, the ultimate constraint upon community values.

The world's religious traditions operate on such schemes of reciprocity, extending them to embrace an afterlife on the belief that what is done on earth will have consequences for the afterlife. Death transcendence is rooted in the human liking for reciprocity and its outcomes. Death exists because of some wickedness or act of disobedience toward divinities, supernatural agents, or some principle of the universe. In Judaism and Christianity there are myths of the "fall" of humanity by which disobedience to divine commands brought death in the first place. This is also evident in Islam. These traditions developed ideas of punishment or purgation in the afterlife as part of a process of finally transcending death. The distinction between hell and heaven, along with the intermediate possibility of purgatory, offers one broad scheme of death transcendence.

In the Indian traditions of Hinduism, Buddhism, and Sikhism, human actions are deemed to have either a positive or negative moral nature in a system of karma that determines one's destiny after this life. Karma is one example of the idea of merit, that "commodity" that is reckoned to belong to people who have behaved well, obeyed commands, or otherwise won the commendation of their society or of the deity of that society.

Merit is a moral means of transcending evil or bad behavior. Just as merit brings praise from society to some of its members in this life so, too, is it reckoned to have an influence over life after death. Merit becomes the basis for salvation in heaven or for a good reincarnation in another life. Merit is integral to much death transcendence. In Christianity, merit plays a major part in theological developments concerning death and is focused in the person of Jesus Christ. He is reckoned to be the one who has, through his morally perfect life and self-sacrifice, gained sufficient merit to ensure the salvation of the whole of humanity and to guarantee them a heavenly afterlife. His resurrection is the quintessential symbol of death transcendence in Christianity.

One of the key debates in the religious Reformation that reshaped European civilization in the 16th century by creating Protestantism focused on who had control of religious merit and whether individuals could earn it for themselves through pious lives and actions. The medieval Catholic practice of paying for masses to be said for the dead to assist their passage through purgatory and on into heaven was seen by Protestants as a gross error. For them, death transcendence was achieved by and through Christ, and by faith in him, and not by reliance on human activity, even if that activity took a religious form.

In the different world of traditional societies with strong ancestor beliefs, merit still operates as the ancestors bless good behavior and curse bad behavior; They may cause the living to flourish or to suffer. Such ancestors have, in one sense, transcended death and now act from the other side of mortality. Because of this, it pays to treat them well and to observe social moral codes.

Ritual Transcendence

Rituals are important in many of these contexts as with rites of passage creating ancestors of the dead, facilitating their transmigration, or ensuring that the dead progress into heaven or paradise. Rituals do this while providing patterns of shared behavior in which ideas and emotions interact with each other and sustain participants. Funerary rites often provide one such context in which the fact of death and emotional reactions to death are given an arena in which to operate. In such contexts, grief, as the response to bereavement, can be both expressed and managed, and individuals and families can be supported by their wider kin and community. Rituals also take time and may involve a series of activities that relate to the changing state of bereaved people. The period of death itself is followed by treating the

corpse through burial or cremation and this may be followed later by the construction of grave markers, by rites performed with cremated remains, or with anniversary visits to funeral or memorial sites. Such a passage of time allows bereaved people to appropriate their newfound emotions of grief and, with time, to look to their future activities. Rituals foster hope rather than despair and in this sense contribute to death transcendence.

Knowledge Transcendence

In general terms, to discover the meaning of life events is, to some degree, to transcend them. To know why something has happened is, already, to begin to come to terms with it and not be "overcome by events." And this feature of discovering why something has happened has frequently been the case with death, as many societies generate patterns of ideas that provide a rationale for ascribing some positive function to death and for managing sets of emotions related to it. Many would identify religion as that sphere of human endeavor that manages these emotions in ways that foster the well-being of society at large. The Eastern religious traditions of Hinduism, Buddhism, and Sikhism developed ideas of a transmigrating spirit that left the body at death in order to enter new forms of future being. Middle Eastern and Western forms of Judaism, Christianity, and Islam took a different route that promised some kind of transformation of the body ready for life in heaven or in some transformation of the earth into a garden paradise.

Behavioral Transcendence

It is seldom enough for human beings to only; think about the great themes of life and death, much more is achieved when they are embodied and enacted. Here, both ethical living and ritual practice have their part in this process of embodiment, of actively participating in the stories and beliefs that give meaning to our lives. This is where funerary rites come into their own as a means of engaging with the truths by which we live. To dig a hole and bury someone in it or to light a funeral pyre and have a corpse consumed by it, is to engage with death in a pragmatic fashion, it is to face the challenge and not to experience defeat. This has been a major adaptive capacity of human beings, not simply to engage with ideas of death in some abstract fashion, but to engage their allied emotions in and through ritual performance. This is not to say that any ritual guarantees the welfare of each individual participating in it, nor that grief is easily controlled, or that the hurts of life are all healed, but it does mean that this occurs frequently enough to have ensured the longevity of group ritual activity. In this sense, rituals may become vehicles of transcendence of death.

Symbols of Transcendence

As self-conscious beings, the idea of death as simple inertness does not seem to correlate with the ordinary sense of being alive. We find it hard to think of ourselves as dead. The analogy of sleep only partly matches the case. There is an empathy in individuals when relating to others that is able to imagine that they feel and think as we do ourselves, and because it is hard to think of ourselves as not existing, it becomes equally difficult to think of others as ceasing to exist, even when they die. This is where a whole series of beliefs emerge to offer symbols of transcendence, central to which are those of the soul and of resurrection.

The Soul

The idea of an immortal soul is a prime expression of transcendence. At the popular level, it sets a difference between the body that rots and some other real source of life that continues after death. This idea of soul as some kind of energy that brings a life force to the body is one of the most successful of all human ideas. Whether in innumerable traditional communities and the world religions or in the classical philosophies of Greece and Rome, some notion of soul or spirit has emerged as a viable explanation of why people may be alive at one moment and dead the next. It has also explained how life comes to babies in the womb. Soul theory is the prime theory of death transcendence. In the 19th century, much was made of it by the anthropologist E. B. Tylor when he devised the notion of animism to describe beliefs in energy entities underlying the life of humans and also of some other aspects of the world. Interestingly, Tylor had wanted to call his idea "spiritualism," but that had, by then, come to be the name for a

kind of religious movement that used mediums to contact the dead. Indeed, Spiritualist Churches now exist in most countries and complement the age-old customs of many cultures that often possessed means of communicating with the dead, itself a form of death transcendence. Just how the soul would survive and what quality of existence it might have in another world is the theme of the merit it may be said to have accumulated. What is true is that behavior in this world is always linked to the status of the soul in the next.

Resurrection

An even greater connection between this life and a life after death is evident in the idea of resurrection. This notion emerged, for example, in Judaism a couple of centuries before the time of Jesus as a way of arguing that martyrs and similar heroes of faith should not die in vain, but have their meritorious lives and acts vindicated. God would raise them from the dead. This general idea of death transcendence shows with great clarity the importance of moral worth to death and afterlife. These ideas focused on the case of Jesus and in the emergent Christian belief that his perfectly moral life and self-sacrifice was vindicated when God raised him from the dead. Christianity then argued that those who believed in Christ would also, in due course, be resurrected. This belief took shape in groups of people who stressed the nature of hope and of trust focused in Jesus, but which they shared among themselves. Indeed, these early church communities even described themselves as being the body of Christ. It was as though their very existence, in life, enshrined the experience of death transcendence. This was reinforced by a variety of experiences and rituals that reflected death transcendence. Baptism, for example, symbolized a death to an old way of life and a rebirth into a new and spiritual form of existence. The waters of baptism were as much a watery grave as they were the waters of rebirth, of a spiritual womb. The Eucharistic meal of bread and wine also spoke of providing a spiritual food that enhance this life in the spirit and would sustain believers into eternal life. This is a good example of how daily phenomena such as a meal could be symbolically utilized to express a transcendence of ordinary life and of death itself. Over time, the Eucharist provided the basic material for use in the ritual of the "last rites," often called in Latin the "viaticum," itself meaning food for a journey. The church prepared the dying person to transcend death. Here the symbolism of baptism, of the Eucharistic meal, and of the Resurrection of Christ combined in a ritual of hope for the future.

Rapture

One of the earliest Christian beliefs was that the resurrected Christ would soon return to earth and gather the faithful around him. Living Christians would rise into the air to meet the coming Christ. But early believers soon found that some of their number actually died before this event took place. This led Paul to write and explain that the dead would not lose out at this great day. Indeed, they would be resurrected and be among the first to come with Christ and then meet the living Christians as they, too, rose in the air. Such dramatic visions of death transcendence gained incredible popularity among some late-20th-century Protestants in the idea of "the rapture." This was presented in story and film forms in a multimillion-dollar level of popular interest in what became known as the "left-behind" motif. With the faithful risen to join Christ, unbelievers would be left behind to suffer all sorts of calamities and evils at the hands of the devil and his hosts prior to the final destruction of the devil and all evil by Christ and his armies. This scenario offers a highly triumphant form of transcendence that deals with death alongside all other evil in one strategic movement.

Enlightenment, Release, and Harmony

Traditions emerging from India have, in addition to adopting transmigration as a partial form of death transcendence, sought mental states that transcend the disquiet of human life in forms of enlightenment that embrace the fact of death. The idea of *moksha,* or release, of freedom from *samsara,* or cycles of rebirth, and of enlightenment itself, nirvana, are all grounded in some sense of transcendence. Other traditions from China and Japan, in Taoism, Shinto, and Confucianism, though each possesses many variant perspectives, tend to approach transcendence in terms of a proper participation in the nature of things as they

are, including the fact of death, often with a commitment to the role of family and ancestors as a wider frame in which human beings come to a sense of fulfilled identity. Transcendence involves an insightful maturing of the moral self in society and in the natural order of life and death.

In every context, the human drive for meaning identifies evils and advocates means of overcoming them. The imaginative dynamics of myths and rituals engage human ideas of merit to foster hope and the possibility of survival against all apparent constraints.

VALHALLA

Valhalla is the conventional English-language rendering of Old Icelandic *Valhöll* (The Hall of the Slain), which, according to Nordic mythology of the Viking Age, is a paradise reserved for warriors who died in battle, presided over by Odin, the god of war. There they feast every night, while by day they fight to the death, reviving at nightfall to feast together once more. These pleasures will continue until the end of the world, when they will join the final battle, fighting alongside the gods against giants and monsters. The evil forces will be destroyed, but so will the earth itself, most of the gods, and presumably the warriors from Valhalla. This cosmic catastrophe is *Ragnarök,* "The Doom of the Gods."

The concept of Valhalla was essentially aristocratic and probably meant little to people of other classes. The basic image comes from the real-life situation of a war band gathered around the leader to whom they have given allegiance, living in his hall and feasting at his expense, and eventually risking their lives in his service. The earliest mentions of Valhalla are in poems honoring the deaths of two kings in battle—Eirík Blood-Axe, a Norwegian who ruled the Viking Kingdom of York (d. 954), and Hákon the Good of Norway (d. 961). They were composed by Icelanders in the service of these kings and are authentic heathen texts, for Iceland and Norway did not accept Christianity until the end of the 10th century.

The first poem, *Eiríksmál,* describes Odin telling the dead *einherjar,* "chosen champions," in Valhalla to prepare to welcome Eirík; they should spread rugs on the benches and bring drinking horns, and the valkyries must proffer wine. When one of the other gods asks why such a fine king was not granted victory, Odin replies that "the grey Wolf gazes upon the homes of the gods"—implying that Ragnarök is drawing near, and Eirík will be needed there.

Hákonarmál opens with a battle scene; at first King Hákon is winning, but then he is summoned by a valkyrie, who tells him it is time for him and his men to go to "the green world of the gods" to join Odin's forces. The gods welcome King Hákon into Valhalla and assure him that although Odin decreed his death, this does not mean that the god has any ill will toward him.

More details about Valhalla itself can be found in *Grímnismál* and *Hávamál,* poems that cannot be precisely dated but are entirely related to topics from heathen mythology. Valhalla is a huge building, gleaming with gold, with 540 doors, and at Ragnarök 800 warriors will go out from each door to face the Wolf (stanza 23 from *Grímnismál*). Other early sources say it is roofed with shields or thatched with spears, and that armor and weapons are piled on its benches.

Over two centuries later, when Iceland had long been Christian, the scholar Snorri Sturluson (1178–1241) wrote a treatise on myths (the *Prose Edda,* ca. 1220) in order to explain the heathen allusions in Iceland's older poetry. Quoting various references to Valhalla, he described its size, the unending supplies of boar meat and mead produced by a supernatural goat, and the pleasure its warriors took in perpetual

fighting and feasting. He also regarded it as the place where the gods assemble, led by Odin.

Snorri also wrote a history of the kings of Norway (*Heimskringla*), in which the first section (*Ynglingasaga*) presents various mythical figures that were human beings whose power and prestige caused their followers to think they were gods. Yet even this rationalized interpretation includes a mention of Valhalla. Snorri says that Odin, who was a wise ruler, made it a law that dead men must be burned, and their possessions laid with the corpse on the pyre—"thus every one will enter Valhalla with whatever riches he had with him on the pyre."

An important feature of Valhalla, both in Snorri's work and in the old poems, is the presence of valkyries, supernatural female beings whose name means "Choosers of the Slain." In *Eiríksmál,* Odin bids them to prepare to welcome Eirík, while *Grímnismál* (stanza 36) lists 13 of them who serve drink at the everlasting feast. The scene in *Hákonarmál* where an armed valkyrie appears on the battlefield to lead the king to the world of the dead expresses what was probably the original concept—fierce war goddesses whose primary task is to decide which warrior shall die. Their individual names reflect their war-like functions, not their role at the Valhalla banquet, for most are combined out of words meaning spear, battle, victory, mail coat, and the like. An alternative name for the whole group is *skjöldmeyjar* (shield-maidens). However, there is evidence from other poems that valkyries also acted as guardian spirits to living warriors, bringing them luck and protection in battle and becoming their lovers.

Archaeological evidence confirms the descriptions from the surviving texts. The island of Gotland, in the Baltic, had a long tradition of erecting carved memorial stones. Some, dating from the 8th and 9th centuries, show an armed man on horseback arriving at a large building with several doors, met by a female figure holding out a drinking horn. The rider might be Odin because the horse has eight legs, as his was said to have; on the other hand, the rider is probably a dead warrior, not Odin the god of war that presided over Valhalla. On the memorial stones below this scene there are others, usually showing a warship or a battlefield, sometimes men feasting, and occasionally a flying figure that could be a valkyrie. The Gotland stones predate the Valhalla poems by several generations and come from a different region, yet they give visual expression to the same nexus of ideas about the warriors' paradise.

Viatical Settlements

The word *viatical* comes from the Latin word *viaticum,* which means "provisions for a long journey." A viatical settlement is the sale of a life insurance policy to a third party (the provider) at a discount (less than face value or death benefit). Ownership of the policy passes to the provider. The provider also becomes the new beneficiary. When the insured (viator) dies, the face value goes to the provider. The provider, who is usually a viatical settlement company, pays the premiums on the policy until the death of the viator. The provider may then securitize the viator's policy with other policies they have purchased and sell interests in the pool, similar to a mutual fund. The provider will require detailed information about the policy. They will want to see the viator's health records and will check up on the viator's health on a regular basis. At the viator's death, they will require a copy of the death certificate.

The viatical industry developed in the 1980s in response to the AIDS crisis. In the early years, viators (insured persons) were usually victims of AIDS who died within a few months of diagnosis and were in need of money to pay for their care

during those months. By the year 2000, AIDS victims were living longer due to new drug therapies, and the market shifted to include the chronically ill and elderly who needed funds to pay for assisted living. Another market has been wealthy elderly people who had purchased large policies when their children were young and who wanted some income from their non-income-producing life insurance policy, as they no longer needed to provide for minor children.

A viatical settlement is different than a clause in a life insurance policy to accelerated death benefits. Under the terms of the life insurance policy, the life insurance company pays out a percent of the policy's face value while the insured is still alive, and the remaining amount is paid to the policy's beneficiaries at the time of the insured's death. A person will usually receive greater financial consideration from a viatical settlement than from accelerated death benefits, but the original beneficiaries of the policy will receive nothing under a viatical settlement, whereas they will get some compensation when using accelerated death benefits. Ownership of the policy changes with a viatical settlement; it does not change with accelerated payments. In both cases, the insured usually receives more money than they would if they surrendered the policy.

Prior to 1996, the money received from a viatical settlement was taxed as ordinary income, whereas payments to a beneficiary at the death of the insured were received income tax-free. Under the Health Insurance Portability and Accountability Act (HIPAA) of 1996, the payments received under a viatical settlement are received tax-free up to the amount paid in premiums over the life of the policy if the person receiving the proceeds has an illness or physical condition such that death can "reasonably be expected" to occur within 24 months, as estimated by a physician. The physician has to attest that there is at least a 70% chance that death will occur in the 24-month period. The letter is only needed if there is an IRS audit, but should be asked for at the time of the sale. In addition, the funds must be paid by a licensed viatical settlement provider if the state requires providers to be licensed or comply with the National Association of Insurance Commissioners (NAIC) standards. The NAIC model requires disclosure, escrow accounts, a rescission period, and pricing minimums. There are no restrictions on the use of the funds.

HIPAA also provides a tax-free benefit to a viator who is certified as chronically ill. To be chronically ill, a viator must be unable to perform at least two of the activities for daily living (such as eating, bathing, dressing, toileting, transferring) without substantial assistance for at least 90 days due to a loss of functional capacity or cognitive impairment (such as Alzheimer's disease). Unlike with the terminally ill, there is no restriction on the life expectancy of the viator, but the funds must be used to pay for or reimburse the cost of the viator's long-term care. There is a limit to the amount received tax-free if the money is not used to pay for long-term care.

The value of the policy is based on the age and medical condition of the viator, the type of insurance policy, the amount of the premiums and how often they are due, the financial rating of the life insurance company that issued the policy, and overall economic conditions. The viator needs to know if they are dealing with a provider (the viatical settlement company that is purchasing the policy) or a broker who is shopping the various providers looking for the best deal.

In addition to giving up all rights in the policy, the viator should know that this settlement may affect their eligibility for Medicaid, Supplemental Security Income (SSI), Aid to Families with Dependent Children (AFDC), and other programs, such as drug assistance. The lump sum received may put the person over the asset limit to qualify or may have to be used to reimburse the state.

The viator and the investor in viatical pools need to be aware of the possibility of fraud. Fraud usually takes one of four forms: (1) the insurance agent lying about viator's health when first selling the policy, (2) viators lying about their health, (3) viators defrauding providers, and (4) providers defrauding viators and investors. An example of the first type of fraud is an insurance agent lying to the insurance agency about the provider's health when the policy is purchased while working with a provider to sell the policy. An example of the second type is the insured lying on the application about an existing medical condition when the life insurance policy was purchased. The third type happens when the viator represents his health to the provider as being worse than it is,

thus gaining a higher amount from the purchase. The last type is the most frequent type of fraud. This is when providers and brokers deceive viators and investors by either giving the viator less money than they should receive or by selling a policy more than once to different investors. Viators should get multiple quotes to be sure they are getting a fair price.

Video Games

A video game is a form of interactive entertainment that involves a human user or multiple users and a user interface to produce visual information through an electronic device, such as an oscilloscope or a computer. Patented on December 14, 1948, the first commercial video game was available for sale in 1971. Since that time, video games have become a major cultural icon, influencing young and old alike. It is this influence that is cause for celebration as a source for enhancing visuomotor skills and perhaps even educational reform; video games also are subjected to intense public scrutiny.

Like other forms of entertainment, such as comic books, motion pictures, and even music and dancing, video games have been the target of both praise and controversy. The release of *Grand Theft Auto IV* (GTA IV) in April 2008 was greeted with waves of hysteria and hand-wringing by politicians, pundits, and some antimedia scholars concerning the effects that this game and games like it might have upon players. Much of the controversy surrounding GTA IV stems from its heavy and graphic use of violence and death-related themes. Although the actual impact of such games on players' behavior appears, in fact, to be negligible, the cultural unease that surrounds violent video games arguably stems in part from our fascination with and revulsion toward death, particularly human-precipitated homicide. Although GTA IV may be an unusually brutal video game in its portrayal of human violence, the theme of death in video games is hardly new, nor is the controversy surrounding death, and particularly violent death, in video games.

Death in Early Games

The first commercially successful video game was *Pong,* a simplistic, nonviolent, tennis-like game released by Atari. *Pong* was something of an anomaly because not even a hint of violence or death existed in the game. Even previous game designs with less commercial success, such as *Spacewar!,* involved battles of machine-on-machine violence that was ultimately won with the destruction or death of one of the players. Although nonviolent games like *Pong* retained a place in the video game industry, and continue to do so through the present day, games that included an allusion to death became more common and popular. Indeed, following *Pong,* most of the video games that reached surging popularity during the 1970s involved some form of cartoon-quality violence and death. Notable examples include *Space Invaders* and *Asteroids,* which featured machine-on-machine violence, as well as *Pac-Man* and *Centipede,* which involved nonhuman critters of various sorts attempting to shoot or eat each other. Other contemporary games, such as *Raiders of the Lost Ark,* started to show primitive versions of human-on-human violence.

The first major controversy over violence and death in video games occurred with the release of a game in 1976 entitled *Death Race*. Based on a movie of the same title, the game featured the player driving a car who would score points by running over screaming gremlins. Unfortunately due to the primitive graphics of the time, the gremlins looked too much like humans. Setting the stage for decades of panic, pundits began to

discuss the possible negative effects of playing video games, partially in response to the controversy generated by *Death Race*. Sales of the game *Death Race* may have been harmed by the controversy, although this early controversy is credited as creating publicity for video games more widely, resulting in increased sales overall.

The shooter game *Bezerk* generated some notice as the first game to actually kill players when Jeff Dailey and Peter Burkowski had heart attacks while playing the game in 1981 and 1982. The game itself hadn't done anything to cause the death of the players, and the timing of the heart attacks was likely coincidental. Nonetheless, the death of two young players during game play increased the notoriety of games at the time.

Death was at the center of most of these early games because it dictated the game flow. Although some nonviolent games like *Pong* existed, many games involved the player attempting to destroy or kill some other object in order to attain the highest score. A lasting legacy of this era that many modern critics of violent video games continue to erroneously assert is that players of modern games (such as GTA IV) "earn points" or "high scores" for committing violent acts. Most games phased out awarding scores altogether by the 1990s, but this idea of games and scores lingers from their early days in the 1970s and 1980s. Even relatively nonviolent games like *Frogger,* where players attempt to guide a frog across a river or street, end with the death of the player, that is, the character in the game, not the player himself or herself, except in the previous two cases.

Therefore, from their early days, video games became more intimately entwined with the subject of death than other media forms. Death-related themes certainly are common in literature and visual media, but they aren't necessary. Comedies, romances, and dramas may avoid death altogether in other media genres. As mentioned, there are also video games in which no allusion to death occurs, such as *Pong* and *Tetris,* but even in many nonviolent games, death is ultimately a necessary ingredient to signal the end of the game.

Death in Modern Games

Themes related to violence and death continued to expand in computer and video games in the 1980s and 1990s. Popular game platforms such as the "shooter" genre (e.g., *Castle Wolfenstein*) and role-playing games (e.g., *Final Fantasy*) began to emerge in the 1980s. As graphics slowly improved and game play began to feature more human-on-human violence, controversy over violence in video games continued. Antimedia activists were particularly concerned about the interactive nature of video games, suggesting that such games may increase aggression more than television was alleged to do, although such concerns were never well supported by empirical data. During the same period, hysteria roiled over the role-playing game *Dungeons and Dragons* (D&D), particularly because this game was more interactive than video games. D&D was posited to cause aggression, suicidal ideation, and delusions. The panic ultimately culminated in a popular made-for-television movie, *Mazes and Monsters,* which implied that D&D might cause psychosis. Given that D&D was a fairly static platform with relatively few changes over time, fervor over the game's supposed ill effects eventually vanished in the absence of any wave of mentally ill players. However, video games continue to evolve, become more graphic and violent, and reach out to a greater numbers of new players. Storylines are also becoming more complex and artistic, and demographics are changing, with adults increasingly becoming the target audience of many games. So although games like *Castle Wolfenstein* that provoked great controversy in the 1980s might seem harmless and quaint by today's standards, they have been replaced by increasingly graphic and sophisticated games.

About the early games, some critics (as with television) complained that the consequences of violence appeared unrealistic. However, once the violence became more realistic, the criticism only increased. Games from the early 1990s, such as *Streetfighter, Mortal Kombat,* and *Doom,* portrayed increasingly bloody consequences of violence and increasingly gained criticism from society's elders. Some critics began positing the existence of juvenile "superpredators" who, raised on violent media, would set off waves of violent crime. Oddly enough, this period in which video games with violence and death themes surged in popularity, rather than sparking a generation of "superpredators" saw precipitous declines in youth and general societal violence to levels not seen

since the 1960s. Indeed, looking at the data on youth violence and video games sales for the years 1996 to 2005 (the only years that both sets of data are available), we find that the relationship between youth violence and video game sales is $r = -.95$, almost perfect, but in the wrong direction. Thus, the video game violence controversy appears to be something of a controversy in search of a crisis. It is quite likely that the controversy is being driven, not by any practical reality, but rather by societal unease with themes of death and violence included in many video games.

Portrayals of Death in Video Games

As with television, an early criticism of video games was that death was not portrayed in a realistic fashion. In early arcade games, another quarter easily revived one's character. Death, in effect, was no big deal; it was all part of the game. Some of this was due to the absence of an integral storyline. Games such as *Space Invaders* or even *Castle Wolfenstein* lacked complex, integral stories. By and large, the technology simply didn't allow for more complex storylines. This early period, once again, probably continues to harm public perception of video games, as some may fail to equate video games with the increasing levels of artistic expression seen in more modern games. Put another way, an early game like *Space Invaders* was "just a game," with no pretensions to artistic credibility. However, more modern games like GTA IV, *Bioshock,* and *Mass Effect* are regularly hailed for their detailed and artistic storylines. This is not a minor issue because the status of video games as either "just games" or valid artistic expression became a central focus for legislation seeking to restrict the sale of video games. This would have brought video games the unique status of being the only form of media (aside from pornography) to be directly regulated or censored by government legislation. So far, the artistic elements of modern video games, along with limited empirical support in the scientific literature claiming the negative effects of video games, have been instrumental in assuring video games the First Amendment protection of free speech in court cases.

Even in more modern action games, death tends to be treated in a transient way. Specifically, to keep the action going, individual deaths come and go quickly, with players moving on to the next target. Relatively little emotional attachment is formed between the player and the majority of characters in the game. This differs from other media in which death may be treated dramatically for emotional effect. Certainly there are movies or television shows in which death, particularly of bad guys, is treated transiently (particularly in the action genre), but this is more common for video games because fast action is generally required to maintain game play. There are exceptions to this. Several of the most modern games, such as GTA IV and *Call of Duty IV,* use "cut scenes" between periods of action to portray the death of important game characters as emotionally laden events. Typically these cut scenes come as "chapter breaks" in the game and serve to move the story forward. Actions occurring during cut scenes are typically not under player control, although players are allowed to play out one integral character's death moment in the game *Call of Duty IV.* The game *Max Payne* was well regarded for its emotional storyline, in which the brutal murder of the main character's family was played out for emotional effect, setting the dreary mood for the game.

Death, however, continues to be fairly transient in most video games. Following death, the player only needs to restart the game, oftentimes from a previously saved location. Although players may grow attached to their characters, particularly in role-playing games such as *World of Warcraft,* the lack of permanency associated with death in video games likely blunts the emotional impact of death. Thus, death in video games may have less impact than in other forms of media in which the death of a character is, barring improbable plot twists, permanent.

The heavy involvement of death-related themes and violence in some video games is likely to keep video games at the center of public controversy for some time to come, at least until a new media replaces video games in the public consciousness. The actual "harm" caused by exposure to such games appears to be negligible, likely repeating the cycle of antimedia hysteria that follows in the wake of new media, particularly those that explore violence and death-related themes. Such controversies likely have less to do with science and more

to do with our own human unease with subjects related to death, dying, and violence, while at the same time we remain fascinated by them.

Wakes and Visitation

The wake is a watch kept by the living over a deceased person before burial takes place. Formerly held as a matter of course when a death occurred, the wake has become a thing of the past in many Western societies in the course of the last half a century, while in others it has been transformed into a family-centered, semiprivate event. Where it has retained its traditional features and functions, it is a highly structured public event, held in the presence of the deceased, in which the deceased's family, kin, and community take part. The duration of the wake and the extent of the ceremony involved reflects the deceased's status in society and the manner of his or her death. In traditional communities, the circumstances of death are reflected in a ceremonial wake. When a person has died a natural death, the wake can be an elaborate event extending over a couple of days. In the past, where death was due to violence, if death had resulted from drowning, if it had occurred before birth (stillbirth), or if the person remained unbaptized when death intervened, the wake could be a scaled-down affair, or it might even be dispensed with, thus reflecting the perceived anomalous nature of the death and the uncertainty about the deceased's status in the afterlife. Nowadays, the tragic deaths of young and old can be occasions for elaborate religious and public ceremonies and intense public participation in the funerary ritual.

After the moment of death passed, the deceased is usually left undisturbed, with his or her face uncovered for a number of hours to ensure that death has actually occurred and to allow rigor mortis to set in. In some cultures this period is thought of as an interval when the soul makes a number of farewell journeys before returning to the body to bid it a final good-bye as it departs forever from this life. When the person has died at home, the commencement of this period of solitude for the deceased is regarded as the moment when the household commences its preparations for the impending wake. This includes making arrangements for a supply of wake goods, especially food and drink, to be made available in the house, but it can also involve the provision of mortuary clothes for the deceased and the ordering of the coffin. The preparations for the wake also involve the rearrangement of space in the house to cater for the viewing of the corpse by family and community, and to enable people to pray for the deceased. The home will also facilitate the dispensing of hospitality to the wake guests, and, where the customs still prevail, will enable the participants to engage in ritual lamentation for the dead and the performance of wake games or other forms of amusement while the wake is in progress. But as the deceased is the central figure of the wake, he or she has to be prepared and readied for public viewing before the wake can begin.

Body Preparation

Whether performed by family or friends or by professional undertakers, the laying out of the corpse involves the ritual preparation of the body by

washing, grooming, and clothing for public display. In traditional societies where the laying out was done by community members, the manner of preparation of a deceased person was strictly codified. Laying out was usually done by women who were versed in the protocol of dealing with a deceased person, but in some places men participated in the preparation of male corpses, while children, male and female, were normally laid out by women. The preparation of the corpse was usually done in silence and movement around the body was from left to right, with the washing commencing at the head and moving clockwise to the feet and then back to the head on the left side. Movement across a corpse was avoided, and domestic animals such as cats and dogs were removed from the house while the wake was in progress. The water and other items used in the preparation of the corpse were carefully disposed of after use, often being consigned to the earth, as the corpse would later be. The deceased was then completely dressed, from head to toe, usually in special clothing, which, in different societies, could be elaborate depending on the secular or religious role or social standing of the deceased or his or her family. The color of the death clothes, such as the use of white garments for young children and unmarried women, might also reflect the age or marital status of the deceased. In some societies it was customary for the deceased to wear shoes, indicative of a belief that death involved a journey to the afterlife. Nowadays, especially in Western societies, people are often dressed in their own clothes, and it is not uncommon for young men to wear the jersey of their favorite football team.

When the remains have been properly prepared for viewing, the deceased is laid out in a supine position with joined hands resting on his or her breast. In Roman Catholic tradition, a crucifix and rosary beads—usually those belonging to the deceased—are placed in the deceased's joined hands. Depending on the customs of the society, the corpse could be placed on a bed, on a hard flat surface such as a table, on a mat on the floor, or in the coffin. The corpse is positioned in the room so that those attending the wake can pay their respects. In Roman Catholic tradition, at least one blessed wax candle is kept burning by the corpse for the duration of the wake. This tradition symbolizes the perpetual light to which the deceased is called. Aromatic plants or other objects might also be placed around the corpse. When all of these measures—temporal, spatial, cleansing, and victualing—are in place, the wake for the dead could begin.

Once the wake has commenced, the deceased has symbolically entered upon the journey to the afterlife. As the wake is generally held in the deceased's presence, his or her transition thus takes place in the company of family and community and is facilitated by their engagement in various procedures involving lamentation, revelry, prayerfulness, and reconciliation in the course of the wake. In many societies, the commencement of the wake was the moment when the ritual lament for the dead took place, usually performed by family members.

The Lamentation

The expression of grief is a natural human reaction in the presence of death. The ritualization of that emotion into a stylized poetic expression of mourning is an ancient cultural inheritance in many parts of the world. While no longer part of the funeral obsequies in Western societies, it is evident that there were specific junctures during the wake when the lamentation was performed and that these corresponded to certain key moments of the obsequies—such as the commencement of the wake, the arrival of family members to view the corpse and partake in the wake, the coffining of the corpse, the removal of the corpse from the house, and the departure of the funeral cortege. The lament was usually performed by women who were skilled in the art of lamentation and, as lamenting the dead was considered an obligation as well as a custom in traditional societies, talented mourners would be hired if no family member was able to fulfill the duty of ritual mourning. The lamentation took place in the presence of the corpse with the lamenting women usually standing and swaying over the deceased, often clapping their hands while performing. The lament consisted of verses chanted in praise of the deceased by the leading keening woman, who then led a coral cry in which the other lamenters and the wake audience joined. This communal lamentation is often described as having a cathartic effect on family and community.

Lamentation was an integral part of the wake ceremony in many parts of the world, and also was revelry and the wake meal, which often contributed

to the quasi-festive atmosphere to the wake. If the deceased was considered a great loss, however—if, for example, the mother or father of a young family had died—then the wake was normally a solemn and sad event.

The Wake: A Celebration of One's Life

In societies where the deceased is considered to be the wake host, the wake guests are thought to partake of his or her hospitality. This may have a basis in reality in cases where the deceased has left instructions about the duration of the wake and had made provision for a supply of food and refreshments to be served to those attending. Wake victuals are normally acquired, usually through purchase and the receipt as gifts from friends and neighbors after the death has taken place, and any food remaining after the wake is disposed of after the corpse had been removed from the house. Traditionally, the food dispensed during the wake was prepared and served by neighbors and friends rather than by the immediate family. The family's main role during the wake was to receive the wake guests and to accept their condolences in honor of the deceased.

It was and is understood that each wake participant will be offered a meal at the house of the wake and a refusal to accept refreshments could be seen as a rejection of the hospitality intended on behalf of the deceased. The meal might be served in the presence of the corpse and the symbolic participation of the deceased in the repast could be signaled by the setting of a place for him or her at table. The festive type of food that still tends to be served at wake events also often confers a quasi-celebratory atmosphere on the occasion, especially if the deceased has passed away after a long and fulfilled life. The provision of alcoholic beverages arguably contributes most to the festive nature of wakes. The provision of alcoholic drink for wake participants was a matter of ongoing concern for the Christian church authorities for many centuries. They consistently forbade bereaved families to provide alcoholic beverages at wakes in order to rid the occasion of behavior they considered inappropriate. Their efforts remained largely unsuccessful for a long period of time, and in the end it was changing attitudes in society toward alcohol consumption and the wake event itself that altered the situation, as late as the 20th century in some places.

Wake Games

Wake games were an integral part of wake procedure in many parts of Europe through the centuries. The playing of games at wakes was known throughout much of the Continent—from Ireland in the west to Hungary, Romania, and the Ukraine in the east, and from Scandinavia in the north to Italy in the south. The *Indiculus Superstitionum,* a list of superstitions compiled by clerics in the year 743, indicates that the clergy at that time were actively condemning *sacrilegia super defunctos* (abuses over the dead). The singing of devilish songs over the dead at wakes by night, the sporting and dancing, and also the feasting and drinking that also took place were condemned by the German cleric Burchardt of Worms, about the year 1000. In later times, the German bishops and their counterparts in Norway, the Balkans region, France, England, Ireland, Scotland, the Isle of Man and elsewhere, also condemned such practices. In Ireland, wake games were repeatedly condemned by the Catholic Church authorities over a period of about four centuries, until they eventually disappeared throughout the course of the 20th century.

Another aspect of wakes, especially in the Roman Catholic tradition, was and is the saying of prayers at intervals during the event. These prayers consist usually of the rosary, which is recited by family and community in the presence of the deceased. Other prayers for the deceased, and for the bereaved family and community, are also said during the wake. The wake ends with the coffining of the corpse and the ritual removal of the deceased from the house when the journey to the church or cemetery begins.

The wake for the dead continues to hold contemporary significance. With its traditional elements of mourning and license and, in some contexts, its prayerful commendation of the deceased to the Christian afterlife, it may be thought of as promoting reconciliation between the deceased and the living, between family and community, and between a Christian and Christian notions of death and the afterlife. With the renewed recognition of the importance of the wake, and especially the viewing of the corpse for the process of grieving, the wake

for the dead is once more gaining in popularity, albeit in a modified form, in some Western societies. Modern embalming techniques are leading to a move away from funeral homes as people are prepared to hold the wake for the deceased in his or her own home—even for a short time—prior to burial so that the funeral can commence from there. This is increasingly seen as a more meaningful way of dealing with the crisis of death.

War Deaths

As a social phenomenon, war is undoubtedly to be met at any time and in any place where the presence of the human species is found. In historical times, the art of warfare evolved into a science of warfare, and its specialists acquired a prestigious status in society. As Georges Dumézil put it, along with the laborer and the priest, the soldier was to become a prominent figure in Indo-European civilization. And there's no suggestion of the absence of this figure in other civilizations as well, even those that were styled as pacifist societies. The German general Claus von Clausewitz coined the famous adage that "war is the continuation of politics with other means," and this pertains to death. War has as its goal to produce dead people, first the death of military people, but also the death of civilians who are present in and around the area of battle. In contemporary warfare, the risk of being killed is as high or even higher for civilians as it is for soldiers.

War as a Lethal Activity

Prior to the time of the invention and implementation of gunpowder around the end of the Middle Ages, the number of dead by feat of war seems to have been rather low. But guns and also the assembling of vast armies were to exact a growing number of war casualties. In most cases, the wounded would face death within a short period of time. For most of these individuals, their fate was undoubtedly worse than that of those who died instantly from their wounds. Along with bullets and knives, gangrene was one of the main purveyors of death in time of war.

The lot of the wounded when neither painkillers, antibiotics, nor anesthetics existed was certainly a gruesome one. To the death by wounds, specific illnesses must be added, such as dysentery or typhoid fever, to which a great number of warriors were to succumb. Perhaps the toll paid to these epidemics has been higher than that paid to the direct effects of the fighting itself. In war, casualties do not mean only men and women killed in combat, but also the wounded and sick whose death may occur much later. There are also the victims of mass slaughter linked to the war operations, and even those victims for whom death penalties were carried out because of desertion or cowardness during battle.

Civilian casualties must be added to this list. Terror air raids conducted during World War II account for a large amount of these victims, adding of course the displacement of huge throngs in

the zones of combat, and voluntary mass slaughters, the *Shoah* being the perfect example.

The total number of dead casualties in the wars conducted at the time of Napoleon was high, an estimated 4 million casualties. But it is from the second half of the 19th century that the concept of "war of attrition" gained relevance. The American Civil War (1861–1865) is said to have cost the country some 620,000 dead, or about 2% of the total American population in 1861. The estimate of 258,000 Confederate war dead derives from incomplete data, because the war was mostly fought in the South and the number of Southern civilian deaths is unknown and not included.

During World War I, the United Kingdom suffered about 885,000 dead, France 1.4 million, Germany about 2 million, and the United States slightly fewer than 120,000. To these figures must be added the dead totals from the other belligerent states, namely those of Russia. For Russia, however, the total will never be known because World War I occurred concomitantly with the Russian Revolution and the Russian Civil War.

World War II was to prove much more lethal: Japan lost 2.1 million, China 3.8 million, Germany 5.5 million, and the Soviet Union an estimated 10.7 million. Taking into account the civilian victims and the prisoner of war (POW) dead, it has been said that the total Soviet Union dead in the war amounted to more than 20 million people. The victims of the Shoah, around 6 million, must be added to these numbers. No doubt the 20th century can be said to have been the more murderous one, ending with the Rwanda genocide of 1994.

Managing the Slain Bodies

The fate awaiting the corpses of war is multifarious. A minority of them will be cleanly buried, with, in some instances, full military honors. Then a vast number of war dead will be placed into collective graves as a provisional measure taken in order to protect the corpses and also to guard against hygienic problems. In case of emergency, the dead will be burned on the spot, a decision made against the regulations of the majority of religious denominations. For those counted among the missing in action, in most cases the bodies will never be recovered.

For armies in the field, the growing number of dead casualties poses acute problems of management. Decisions must be made quickly, for the presence of dead and decaying bodies on the battlefield or in bombed buildings gives way to a high risk of epidemics. In the modern attrition wars, many soldiers die of disease, forcing the authorities to cope with this additional and significant loss of fighting ability. And many others die in POW camps.

Administration services, with a numerous personnel, are required to deal with the dead in the new form of warfare, namely mechanized. The first duty is to identify the dead, thereby giving them back their names. The second task consists of informing the families of the dead soldier's fate. Thereafter is the gathering of the corpses to be buried in cemeteries or collective graves. On occasion, orders would be given to combating units to get rid of the corpses by burning them in heaps. These duties last for a long time and even after the war has ended, as is so eloquently described by Bertrand Tavernier's 1988 film, *La Vie et rien d'Autre* [*Life and Nothing Else*]. For then came the time of exhuming the dead, of trying once again to identify the dead, of reuniting them in definitive cemeteries (to be administered by special offices, like the Commonwealth Graves Commission), and to organize the appropriate ritual ceremonies. This often went through the reclaiming of the dead bodies by their close relations, so that a private ceremony could be conducted.

Piaculary Expressions

Either personal or collective, the rites conducted were properly of the piaculary type. *Piaculary* means expiatory, atonement, or making amends, and for the survivors, these rites provide an occasion for expressing a normative feeling of expiation toward the dead warriors. The main problem is that of the bereavement. For a dead soldier's family, it is hard to go through the bereaving period in the absence of a grave where they can be sure of the presence of the loved one. It is on this grave that the funeral rites can be performed. But where the corpse is not involved, the ordinary three stages of the ritualizing process are condensed into one lone staging to include the farewell rites, the translation rites, and the welcoming rites. However, when family members and close friends are able to attend the transfer of the mortal remains from a provisional burial place to a definitive one, then the second stage of the committal process can

also be performed, be it in symbolic way if the transfer journey has been reduced to a short procession on the graveyard ground.

The Atonement Process

The atonement dimension of the ritual process is twofold. First there is atonement for the killing itself: The close ones have not been able to prevent the beloved one (in the vast majority of cases a male in the prime of his life) to fall on the battlefield or to die in a hospital from wounds or diseases resulting from his presence on the front. Even when the patriotic cause is endorsed by the soldier's family, the glorious dead nevertheless remains dead, whose death should not have occurred at so fresh an age, and one must ask for some forgiveness regarding this grievous event. For the surviving friends of the dead, a certain sense of injustice may be experienced, such as asking, "Why him and not me?" This feeling has proved rather common among the survivors of the extermination camps, but it has also occurred among those who went more or less safely though the terrible ordeals of combat.

The second part of the atonement on behalf of the close relatives of the dead lies in the provisional burial on the battlefield, the equivalent to an indecent way of disposing with the dead body, more so when no mortuary rites have been performed. This indecency must be redressed, because what happened to the dead body can be accounted for an undue wrong. Thus in many cases, the mortuary rites held at the definitive grave take the form of a public ceremony, often of a mixed religious-civic character. In an attempt to reward the glorious dead hero with a reparation gesture, the ceremony may be grandiose. The burial in the hallowed place of the Tomb of the Unknowns is the most striking illustration of this proceeding. In this special ritual staging, extolling this highest collective heroism is mixed with the deepest collective atonement. A special mention must be made of the fallen soldiers whose corpses had been cremated, often against their religious convictions. And this requires a specific kind of repentance, thereby increasing the piaculary aspect of the ritual.

Monument to the Glorious Dead

After the wars of the modern times, societies generally proclaimed that all those who died during combat were to be thought of as glorious. Even those who ambushed (the French *embusqués*) were drafted in the glorious host. Those who do not qualify for this membership, such as deserters, cowards, and mutineers shot as examples, were carefully expelled from all official references. Their names would not appear on the countless monuments dedicated to the memories of the official glorious dead. These monuments were erected in the wake of the wars, whether these were won or lost, in the centers of towns or villages, in local civilian cemeteries, or on the spots of particularly hard fighting.

War monuments, especially after World War I, became a part of the human landscape. Ceremonies are held around them on remembrance days, attended by veterans, local authorities, bereaved families, schoolchildren, and members of patriotic associations, for example. The monuments to the glorious dead are considered symbols of national heroism, and they serve as rallying spots for patriots, sometimes representing the spirit of vengeance as well. For the militants of patriotic causes, the glorious dead whose names were inscribed on the monuments testify to the collective sacrifice of which they were a part. In proclaiming that this sacrifice should not be in vain, the politicians enlisted the war dead in political debates, either of a pacifist stance or a revengeful one.

Glorifying War Dead

In some countries, names of the deceased are given to streets and public squares, thus representing another method for glorifying the dead. Glory is a concept that transcends all the petty impediments hindering the conduct of a truly glorious war. The glorious dead, before being killed, often suffered much in their trenches, their boats, or their planes, but the fact that they died for their homeland pushes all these ordeals into oblivion. What is given in the official discourse is their glory. Hence, imagine the shock experienced by the readers of books dealing with the unglorious, dirty side of warfare, such as *Le Feu* by the French Henri Barbusse or *Opfergang* by the German Fritz von Unruh.

National shrines dedicated to the glorious dead represent a similar ideology, albeit on a higher level as local war monuments. Verdun, with its "trench of the bayonets," is an example of such places of national worship.

In some cases, the cult devoted to the glorious dead is staged at a national place of honor, such as the Tomb of the Unknowns or the British Cenotaph, located in Whitehall, London. This simple marble monument, suggesting a coffin borne by a high pedestal, displays on one of its faces the simple words, "The Glorious Dead," symbolizing all the combat victims of the British Empire since World War I. On the nearest Sunday to November 11, a grandiose staged ceremony takes place at the site. Its rituality seems immutable: First, music is played by a mixture of various military bands, then the Anglican Bishop of London delivers a short homily, then the Queen and the members of the Royal Family, followed by the prime minister and other political leaders, lay wreaths on the Cenotaph's feet, followed by the military chiefs and the High Commissioners of the Commonwealth Nations, to end with the leader and other members of the Royal Legion of veterans. After the official part of the event, a long cortege of veterans and veteran-related people passes along the Cenotaph in military fashion. What is remarkable is the blend of civic and religious pageantry, the last one being restricted to the official Church of England, though representatives of other denominations, led by the Catholic primate, also attend the ceremony. This funeral ritual at the national and international level is clearly a piaculary ceremony. That is, the deceased gave their lives, we praise them for their sacrifice, but we also seek their forgiveness.

The Unknown Soldier

In some countries, after the end of World War I, a corpse has been chosen from the unidentified war dead to become the unknown soldier. This was later transferred, along with a display of emotional military pageantry, to a national shrine in a highly symbolic place, such as the Arc de Triomphe in Paris or the Congress Column in Brussels. The unknown soldier thus becomes the son of mothers who could not find their own sons, a metonym for all the fallen soldiers who gave their lives to protect their homeland, thereby transforming mothers into a powerful living metaphor. The rites used to evoke the presence of this unidentified corpse bear various aspects of funeral rites in general, which are raised to the status of a commemorative ceremony, at the same time atoning for all these "glorious dead" and exalting the national community.

What remains of the versions of the tomb of the unknown soldier in various countries is a place of meditation for visiting heads of state or government. The surviving ritual (including other war monuments of national significance), the laying of a wreath, functions to allow homage to be rendered. That this homage is paid to the glorious dead of ancient, almost forgotten wars is meaningful, for as the French philosopher Alain once announced, the dead govern the living, and this is true as well of individuals as of whole nations.

Wax Museums

Well before Madame Tussaud's artistic brilliance came onto the London art scene in the late 1700s, societies used waxworks to immortalize their culture and the deceased. Historians trace the earliest forms of wax figures to around 3000 B.C.E., in what is now modern India. Egyptians used the wax effigy as a way to retain the soul of the person after death. The Greeks and Romans used wax effigies in funeral processions and particularly for displaying prominent political figures of the time. Early, and to some extent contemporary, Christians often used wax figures to depict iconic people, such as Jesus and Mary. This entry examines the history of the contemporary wax museum

and the functions of the contemporary wax museum in modern society.

Although the contemporary wax museum does not serve the religious or spiritual functions it once did, it still has significant social, cultural, historical, and political functions for society. The content and meaning of the wax statue in contemporary society has changed since the times of death masks and the religious offerings of wax figures during the Middle Ages. However, the wax museum—the medium for displaying waxworks in contemporary society—still immortalizes the deceased and crystallizes pieces of its society's history and culture.

Madame Tussaud and the Contemporary Wax Museum

Modern wax museums evolved from the traveling wax curators of Britain's Victorian Age. Like the state fair of today, the traveling display gave the general public an opportunity to view famous people they had only heard or read about. As a form of entertainment, Phillipe Curtius, Madame Tussaud's mentor, initially designed his wax displays for the elite, and as an opportunity for the public to interact with people they would not normally meet. Wax museums allowed the wealthy to pretend they were a guest of some royal figure or famous celebrity. For example, one of Curtius's most popular attractions was the representation of King Louis XIV and Marie Antoinette holding a dinner party, where the public could pay their entrance fee and sit with royalty.

Today, the name Madame Tussaud is synonymous with wax figures. Born Marie Grosholz in 1761, in Strasborg, France, she became an assistant to Phillipe Curtius, from whom she learned wax modeling. Tussaud knew many of the leading figures of pre-Revolutionary Paris and indeed was invited to live at the Royal Court in Versailles to be the art tutor to King Louis XVI's sister. Her sympathies toward the king led to her incarceration during the Revolution, and she was forced to make death masks of the royalty she once adored. After her release, she returned to work for Curtius and inherited his collection of waxworks after his death in 1794. In 1802, she went to London and, prevented from returning to France by the Napoleonic Wars, exhibited her waxworks collection throughout Great Britain and Ireland.

Madame Tussaud's attractions are particularly adept at appealing to the local culture, while also providing the opportunity to see wax figures of people from around the world. The London collection houses figures of British royalty and politicians, but also includes figures such as Albert Einstein and Pablo Picasso, while the Las Vegas collection houses the Blue Man Group as well as popular sports icons and movie stars.

The Functions of the Wax Museum in Contemporary Society

Wax museums function to reproduce, crystallize, display, and construct social, cultural, and political images. Commemoration of heroes and villains reflects a society's value system. In this area, it is suggested that the hero image represents a positive deviation from the society's general value system, whereas the villain image represents the negative deviation. As the contemporary wax museum commemorates its heroes and villains, it is also reinforcing a collective social image. In a sense, heroes and heroic events provide social solidarity among individuals.

In similar fashion, the wax museums display waxworks of the collective image of the villain embodied in political leaders, such as Adolf Hitler and Benito Mussolini, and social villains, such as Anton LaVey. Some wax museums, such as the Criminals Hall of Fame Wax Museum in Niagara Falls, Ontario, focus exclusively on displays of the villain, such as Al Capone, Charles Manson, and Jesse James. Although the museum is intended to entertain, it also serves to reinforce the cultural norms of society and crystallizes the collective image. The wax museum is a reproduction of culture, confirming the relevance through its cultural images. The Museo de Cera in Veracruz, Mexico, for example, reinforces the culture of contemporary Mexico with waxworks of public figures of sports, politics, and the arts.

Wax museums allow for members of society to see who society vilifies and idealizes, creating an opportunity for social control over members. Visitors to the Famous Criminals Hall of Fame Wax Museum can see the image of Jeffery Dahmer looking into a refrigerator with human body parts. Criminal wax museums can vivify and show the deviant behavior by the significant effect of three-dimensional construction of wax images.

The display of heroes and villains in wax museums serves to identify boundaries of social control.

The Human Imagery Museum in Nakhonpathom, Thailand, promotes and propagates Thai society. Similarly, the National Wax Museum of China was commissioned by the Chinese government to display collective images of China's political and social leaders. In the West, the wax nativity scene in Madame Tussauds in London epitomizes this idea. In each of these examples, the wax museum reinforces the political and cultural status quo. But contemporary wax museums also provide a collective memory while portraying historical shifts in moral boundaries. The Great National Blacks Wax Museum located in Baltimore, Maryland, represents a collective memory through the representation of the history of race relations in America. Similarly, the Museo Historico de Cera in Buenos Aires, Argentina, displays numerous waxworks depicting the traditions of the culture of the region prior to Spanish colonization and the violent battles between the Querandi natives and the Spaniards during the process of colonization.

Symbolic Immortality

The wax museum offers symbolic immortality. Photographs provide one way of continuing life after death in symbolic ways, but for public figures, the wax museum is a medium for individual symbolic immortality. In portraying symbolic immortality, monuments transmit culture from one generation to the next. The wax statues of Babe Ruth and Albert Einstein in the Royal London Wax Museum in British Columbia, Canada; Joe Louis and Jack Dempsey in the popular Wax Museum at Fisherman's Wharf in San Francisco; and Duke Ellington and Bob Marley in Madame Tussauds in New York represent such symbolic immortality.

In summary, the wax museum embodies a society's value system, its historical, cultural, social, and political images. Ultimately, the contemporary wax museum is a rich chronicle, a commemoration of society's heroes and villains that resonates with society's collective conscience through its symbolic images. It allows people to interact with history's public figures. Through the wax immortalization of heroic and villainous people, the contemporary wax museum will continue to transmit a society's cultural, social, and political chronicles.

Widows and Widowers

Widows and widowers are women and men who have survived the death of their spouse. Widowhood may be conceptualized as both a life transition and a personal status. Widowhood is a transitional event because the loss of a spouse is typically accompanied by high levels of psychological distress as the newly bereaved person adjusts to life without one's spouse. Yet widowhood also may be conceptualized as an enduring social role or identity, just as "married person" is a social role. Although the transition to widowhood is often associated with grief, depressive symptoms, and declines in physical health, most bereaved spouses are resilient and return to preloss levels of functioning within two years following their loss.

The likelihood of becoming widowed and of remaining widowed and the consequences of spousal loss vary widely by gender, age, and sociohistorical context. Gender is one of the most powerful influences on the experience of widowhood. In all developed and nearly all developing nations, women are more likely than men to outlive their spouse, reflecting men's higher rates of mortality and the tendency of women to marry men slightly older than themselves. Widowhood is also an older women's issue; life expectancy has increased steadily over the past century, and spousal loss overwhelmingly

befalls older adults. As such, widowhood has important consequences for the physical, economic, and psychological well-being of older adults.

Gendered Patterns of Widowhood

Highly visible images of distraught widows and widowers often feature the young—the youthful brides of fallen soldiers in the Iraq war or the junior executives who lost their wives on September 11. Yet widowhood today is a transition overwhelmingly experienced by people age 65 and older. Of the 900,000 people who become widowed annually in the United States today, nearly three-quarters of them are age 65 or older. Widowhood patterns mirror mortality patterns. The death rate, or the number of all people who die in a given year per 100,000 people in the population, increases sharply beyond age 65 (see Figure 1). Life expectancy at birth today is 76 for men and 80 for women, so women are much more likely than men to outlive their spouse.

Women also are more likely to remain widowed, given widowers' greater propensity to remarry. Among people age 65 to 74 in 2006, 26.3% of women and just 7.3% of men are widowed. These proportions jump to 58.2% of women and 20.5% of men age 75 and older (see Figure 2).

Widows are far less likely than widowers to remarry because of the death of opposite sex peers. Among men and women age 65 and older in the United States, the sex ratio is 1.5 women per every man. By age 85, this ratio is more than 3 women per every man. As a result, few widows have the opportunity to remarry. Additionally, cultural norms encourage men to marry women younger than themselves, so widowed men may opt to remarry a younger woman, whereas older widows do not typically have access to a similarly expanded pool of potential spouses. Recent studies also reveal that women in contemporary Western nations have a weaker desire to remarry; many women report that they do not want to resume the homemaking and caregiving chores that often accompany marriage.

The Personal Consequences of Widowhood

Widowhood often is accompanied by emotional distress, physical symptoms, compromised health behaviors, potentially disruptive residential relocations, and economic strains triggered by both the direct costs of medical care and funeral arrangements at the end of a spouse's life, as well as the loss of the (working age) spouse's income. In this section, we describe the consequences of widowhood for older men and women. However, it is

important to note first that the widowhood experience is different for older and younger adults.

The age at which one experiences a major life transition shapes both the nature and context of the event. Life events that occur unexpectedly or are "off-time" (that is, earlier or later than one's peers) are particularly distressing. Youthful deaths typically are unexpected, leaving the young bereaved spouse little time to prepare psychologically or financially. Many younger widows and widowers face the challenge of raising children on their own, often while working full time. Many may be robbed of a long future with their spouse, and few have peers to turn to for empathy and support, as spousal loss is rare among young people.

By contrast, most older people experience the loss of their spouse after decades of marriage. They have raised their children, celebrated the births of their grandchildren, and have enjoyed at least a few years of relaxation together after retiring from the workforce. For most older spouses, widowhood comes "on time," rather than prematurely. Older people are often prepared for the transition, and they have friends and peers they can turn to for emotional strength, practical support, and camaraderie. Older adults also differ from their younger counterparts in how they respond emotionally to stress. Psychologists document that older adults have lower levels of "emotional reactivity." This means that they have a heightened capacity to regulate their emotions, and they report less extreme emotional responses than do younger people. As a result, their grief reactions tend to be less intense and much shorter lived than those experienced by young adult or midlife widows and widowers.

Who Adjusts Better to Spousal Loss: Men or Women?

Although widowhood is much more likely to befall women than men, both genders face distinctive challenges as they cope with a partner's death. An estimated 40% to 70% of older widowed people experience a period of 2 weeks or more marked by feelings of sadness immediately after the loss. Gender differences in emotional distress following late-life widowhood have been researched extensively, yet results remain inconclusive.

Researchers agree that gender differences in psychological health in general need to be taken into consideration before one can conclude that widows or widowers fare systematically worse. Women have higher rates of depression than men; most studies estimate that women's rates of depressive disorders are between 50% and 100% higher than men's. In contrast, men have significantly higher rates of alcohol and drug dependence and antisocial behavior disorders than women. Studies that compare only widowed women and men may find that widows are more depressed, but cannot necessarily attribute this gender difference to the event of widowhood. Gender differences in psychological reactions to the loss of one's partner may be understated (or overstated) in studies that do not control the pathway variables that may account for the observed gender gap. The key pathways that link bereavement to psychological adjustment reflect gendered patterns of social interaction over the life course, characteristics of the late marriage or long-term relationship, and the context of the partner's death.

Understanding Gender Differences in Bereavement Experience

"His" and "Her" Marriage

Adjustment to spousal loss is inextricably linked to the social roles one held both within and outside of marriage. Feminist writings, exemplified by the work of sociologist Jesse Bernard, have argued that traditional marriages—where men specialize in the breadwinner role and women are responsible for childbearing and childrearing—benefit women much less than men. Marriage brings men health, power, and life satisfaction, but the institution subjects women to stress, dissatisfaction, and the loss of self. According to this perspective, women are purported to suffer less when a marriage ends because they have less to lose. However, recent empirical studies counter that marriage benefits *both* men and women, yet in different ways. Women typically benefit economically, whereas men receive richer social and psychological rewards. These gendered patterns of advantage and disadvantage within marriage provide a framework for understanding gender differences in adjustment to spousal loss.

Economic Issues

One of the most widely documented sources of distress among widows is economic strain. Widows are more likely than widowers to experience economic hardship. Although age-based income assistance programs, such as Social Security, provide economic support for older widowed people, the bereaved remain significantly worse off than their married peers. Widowed people are more likely to live below the poverty line than their married counterparts, and they tend to cyclically re-enter poverty after losing their partner. Costs associated with the funeral, medical and long-term care, or estate-related legal proceedings can devastate the fixed income of older adults. For younger women, remarriage may be a pathway out of poverty, yet demographic constraints make this option difficult for most older women.

Widows' economic disadvantage reflects lifelong patterns of gendered inequality. In traditional marriages, wives tended to childrearing and family responsibilities, while husbands were responsible for supporting the family financially. As a result, older women have had fewer years of paid work experience than their male peers. Women's accumulated pension and Social Security benefits based on their own earnings are typically much lower than those based on their husband's lifetime earnings. Moreover, the pension benefits and Social Security income of their husband may not be available or may be reduced after his death. Older widows who try to re-enter the labor force may also lack the experience to secure a good job, or they may face age discrimination.

These financial stressors, in turn, are an important source of psychological strain. Stressful life events, such as widowhood, may cast off a chain of secondary stressors that have either direct or combined effects on the survivor's well-being. Financial strain is a risk factor for depression. Bereaved women who lack expertise or experience in paying bills and making major financial or legal decisions may face considerable anxiety when forced to assume sole responsibility for the financial management of the household.

Social and Instrumental Support

In traditional marriages, women typically provide emotional, social, instrumental, and health-promoting

support to their husbands. As a result, men often have difficulty in managing household tasks, maintaining their own health, and seeking out alternative sources of emotional support after their wives have died. For these reasons, men are more likely than women to experience physical health declines, increased disability, and heightened risk of mortality after their wives die. While popular lore claims that these men may "die of a broken heart," research shows that it is the loss of a helpmate and caretaker that is really the culprit. Wives typically monitor their husbands' diets, encourage them to exercise, remind them to take their daily medications, and urge them to give up their vices, like smoking and drinking. When their wives die, these healthy reminders slip away. Widowers are more likely than married men to die of accidents, alcohol-related deaths, lung cancer, and chronic ischemic heart disease during the first six months after their loss, but not from other causes that are less closely linked to health behaviors.

Even worse for men is that their wives often are their primary (or only) source of social support and integration. Current cohorts of older men, often raised to be strong and silent, have few close friends with whom they can share their private concerns. Wives often are the family "kinkeeper"—the one who arranges dinner parties with friends and organizes outings with the grandchildren; when a man loses his wife, he also loses his connection to his social networks. Social support is essential for maintaining physical and emotional health, especially in later life.

In contrast, women's richer sources of social support over the life course are an important resource as they adjust to the loss of their husbands. Widows typically receive more instrumental and emotional support from their children than do widowers, given mothers' closer relationships with their children throughout the life course. Women also are more likely to have larger and more varied friendship networks than men, and these friendships provide an important source of support to women as they cope with their loss. These patterns reflect lifelong processes of gender-role socialization (particularly in current cohorts of older adults), where women are raised to develop close and intimate interpersonal relationships, and men are socialized to be self-reliant and independent, with few close confidants other than their spouse.

Other Influences on Widows' and Widowers' Experiences

Marital Quality

The extent to which widows and widowers mourn the loss of their late spouse also is linked to the emotional climate of the late marriage. Early research, guided by the psychoanalytic tradition, suggested that people with the most troubled marriages suffered heightened and delayed grief following their spouse's death. This perspective held that people who had conflicted or ambivalent marital relationships find it hard to let go of their spouses, yet feel angry at the deceased for abandoning them; as a result, they experienced elevated grief. Recent research shows, conversely, that people in conflicted marriages mourn less for their spouses, while people with the most loving marriages grieve most upon their loss.

The Nature of the Late Partner's Death

Late life loss is distinct from earlier losses in that it typically occurs at the end of a long chronic illness, and intensive caregiving is often required during the ailing person's final weeks. The timing of and conditions surrounding a partner's death have implications for the psychological adjustment of the bereaved spouse. On one hand, the knowledge that one's partner is going to die in the imminent future provides the couple with the time to address unresolved emotional, financial, and practical issues before the actual death. This preparation for death is believed to enable a smoother transition to widowhood. However, long-anticipated deaths due to chronic illness may be accompanied by potentially stressful experiences, such as difficult caregiving duties, financial strains imposed by long-term care, emotional isolation from other family members and friends, and neglect of one's own health symptoms.

The conditions of a spouse's death can affect women and men in different ways. For widows, sudden spousal deaths are associated with greater psychological distress, while widowers mourn most for their wives when they died after a prolonged illness. These relationships reflect gendered patterns of socialization and social interaction. Men typically have fewer sources of social support than do women and may become even more

emotionally bonded to their wives during their final weeks. Men also may have few same-sex peers who are caring for a dying spouse, and thus have few sources of peer support and advice. Women, in contrast, may rely on their female friends' direct experiences with spousal illness to prepare them for the difficult dying process and thereafter.

Partner Death Among Gays and Lesbians

Researchers know little about how older gays and lesbians adjust to the loss of their long-term life partners. This lack of research reflects the fact that no official statistics are available for same-sex unions, given the lack of social and legal approval for these relationships. Older homosexuals may face both unique challenges and advantages as they cope with loss.

Bereaved gays and lesbians may encounter conflict with their deceased partner's family, particularly with respect to the dispersion of personal possessions following death. Legal rights extended to heterosexual married couples are not typically available for same-sex couples, including the opportunity to make health care and end-of-life decisions for ill partners. Bereaved same-sex partners may not receive sufficient emotional support upon loss because the end of homosexual relationships may not be recognized or acknowledged in the wider community.

However, gays and lesbians have some resources that may enable better coping with partner loss. They may create their own support networks of friends and selected family members. They also may be more likely than their heterosexual peers to enact flexible gender roles throughout the life course. Because they are not bound to traditional gender types and family roles, they may be better prepared to manage the daily challenges and responsibilities faced by the newly bereaved.

Future Trends and Research Directions

The research presented thus far provides a detailed portrait of older widows and widowers in the United States in the late 20th and early 21st century. However, this research describes late life spousal loss as it is currently experienced, and not how it may be for future cohorts of widows and widowers. Current cohorts of older adults were born in the early 20th century, and many conformed to rigid gender type marital roles as they formed families in the mid-20th century.

Future generations of older adults, by contrast, will have educational, family, and career histories that are different from those of past generations. Current generations of young adult women have higher levels of education, more years of work experience, and higher personal earnings than do earlier cohorts of older women. As a result, they may be less dependent on their husbands for income, as well as for support with traditionally "male" type household tasks, such as home repair or financial management tasks. Likewise, each cohort of men is more likely than their father's generation to participate in homemaking and childrearing tasks. As the boundaries demarcating traditional gender roles in marriage blur, widows and widowers will likely face fewer challenges (and less anxiety) as they manage homemaking, home maintenance, and financial management tasks after their spouse dies.

At the same time, adaptation to spousal loss may become more difficult for future cohorts of widows and widowers. Two important demographic trends—increasing divorce rates and declining fertility rates—may have important consequences for how the bereaved adjust to loss. While past generations of older adults often stayed in difficult marriages because of cultural or religious prohibitions against divorce, more recent cohorts of spouses can freely divorce if their marriages are unsatisfying. If men and women dissolve their troubled marriages, then those who remain married until late life may have particularly warm and close relationships, and may be the most grief stricken upon their loss. Declining fertility rates mean that older adults will have fewer children upon whom they can rely for social support following spousal death.

As life expectancy continues to increase, the nature, cause, and trajectories of death will change; the context of death has important implications for older adults and their soon-to-be bereaved spouses. For example, medical advancements that extend the length of life may create the need for more intensive spousal caregiving, a task that typically falls to women. If the duration and intensity of late-life caregiving increases, and if wives continue to bear the burden for personal care, then cohorts of women entering old age in the future may face a more difficult adjustment to spousal loss. Further exploration of the way that social,

cultural, and technological forces shape the bereavement experience will provide knowledge of practical and political importance for future generations of bereaved spouses.

WITCHES

References to witches are found in a variety of historical and cultural accounts. Witches are thought to be involved in witchcraft, an activity that involves the manipulation or deciphering of supernatural forces. Witches do good things, such as defending against evil spirits, bringing prosperity, casting good spells, and healing. Witches also are believed to engage in evil activities, sometimes using their power to achieve questionable and bad goals, such as concocting love potions, casting spells, or contacting the dead. One illustration is the practice of voodoo, wherein a priest or priestess can revive the dead, who may, in turn, evolve into a zombie, that is, a revived corpse without a soul. Lacking a soul and free will, the zombie is thus controlled by the priest or priestess. This belief has apparently impacted modern folklore, found especially in horror movies, which developed this theme and created an image of mindless, flesh-eating monsters.

Within the Western European tradition, the connection between death and witches is identified in two related main themes: necromancy and the pact with the devil. Necromancy is historical and is easily traceable to biblical passages. The most famous biblical account is focused on King Saul and a visitation to the Witch of Endor before the final battle in which the king lost his life (Samuel 1:28). King Saul was an antiwitch activist, and his seeking the help of the Witch of Endor to conjure the result of the next day's battle can be considered a major social infraction. Still, the Witch of Endor managed to animate the spirit of the Prophet Samuel from the dead and, after complaining that his rest was disturbed, he gives King Saul the terrible prophecy. This biblical account highlights an important aspect of the witch: the power to control. Within this context, the Witch of Endor forced the appearance of Samuel against his wish. In this case, a necromancer witch could thus use witchcraft to force the dead to appear before the living and obey their wishes. The fact that the Witch of Endor was portrayed as a woman serves as an important omen. Within ancient Jewish law, the view and attitude toward practicing witches is found in the divine command, "Thou shalt not suffer a witch to live" (Exodus 22:10).

This historical conception attributes a special and powerful position to witches vis-à-vis that of deities. The witches' knowledge of how to cast a spell and to produce charms and potions enables them to force various deities into action that they would not have otherwise undertaken, including a special power to engage dead deities. During the Greco-Roman period, witches were thought to consult with the dead about future events.

The Pact

The Old Testament of the Bible provides an account of the fall of Satan, noting that the angel's leader Semjaza (also known as Azazel) and his followers bound themselves together by oath on Mount Hermon and descended to earth where they took wives and begat giants. The lustful and cruel deeds of these angels wrought such destruction and wickedness that God sent a huge flood (referred to as "the deluge") to cleanse the earth. And so, Semjaza and his band were sentenced to be buried under mountains until the Day of Judgment, when they were to be forever cast into the abyss of fire.

Once the existence of Satan was created and associated with evil and death, the stage was set for the next, much later stage, or what became known as the "pact." The principle upon which the pact is based was to emerge during the European witch craze of the 1400s to 1600s and the infamous Salem, Massachusetts, witch trials that would eventually hold sway in contemporary popular culture.

Emerging during the European witch hunts of the 15th to 17th centuries, the concept of the pact was to transform the public perception of witches from engaging in practices that generated social good as well as bad purposes into a completely evil entities. During a historical period in which unattached women became the primary targets of a clergy dedicated to reestablishing the supreme position of the Church in the lives of the lay population, witches became socially redefined as having lost their ability to do good because they had, in turn, become sexually dominated by Satan.

One of the most influential 15th century documents that addressed witchcraft was the 1480s *Malleus Maleficarum* or "The Witch's Hammer," which explained that only Satan could satisfy the insatiable sexual appetite of women. The religious-driven conception of the relationship between demonology and witchcraft was based on the religious argument that the world served as a battlefield upon which an ongoing struggle between Satan and God was portrayed. The social fear was that Satan might win this battle and turn the world into hell. Thus, the ongoing battle was a "battle for the souls," based on the assumption that after death the soul will either go to heaven or to hell. Heresy evidence, a major element during the dominance of the European witch craze, was that Satan recruited servants, mostly women, by signing a pact with them and turned them into his sexual subordinates. The social perception was that the pact again provided female witches the opportunity to commit evil deeds. In turn, the souls of these women belonged to the devil, and these women would serve in hell upon their death.

The main expression of the witches-pact-death connection became known as the Black Sabbath. On this day, it was believed witches, riding on broomsticks, would descend upon a cemetery where they would pay homage to Satan and his devils (frequently in the form of a stinking goat) and reaffirm the pact with the Devil.

The modern popular version of the pact stipulates that while signers may be offered wealth, good health, and power, they will not necessarily become witches, but they will certainly lose their souls to Satan when they die. This contemporary weakened correlation between witches and death is found in modern music pieces, books, and movies, such as *The Devil and Daniel Webster* (by S. Benet and movies 1941 and 2004), *Constantine* (2005), *Faust* (by J. Goethe), or TV series such as *Reaper* or *The Collector*.

Wrongful Death

On the civil side of the American legal system, there are three general types of monetary compensation in the wrongful death of a person: One is noneconomic losses, or the fear, anxiety, pain, suffering, and loss of enjoyment of life of deceased prior to death. The second is the economic losses suffered by the deceased, the deceased's estate, or survivors, including medical bills, funeral expenses, lost income, and the economic value of lost services. A third is "grief and sorrow," or "grief and bereavement"—mental and emotional suffering, not of the deceased, but rather the emotional distress, grief, and sorrow to a class of people related to the victim. Some states allow such compensation to all family members, including siblings; other states restrict the "protected group" to parents and children. Despite the cold harshness of such laws, some states still deny anyone damages for grief and sorrow of a loved one. Often such grief is costly to survivors, who must undergo counseling and medical treatment for emotional distress and passing through the six stages of grief—denial, anger, bargaining, depression, guilt, and acceptance.

Wrongful death actions in some states may describe two separate and distinct legal claims. One concept is antemortem damages caused to the deceased before death (often called a survivorship claim); the other claim is for losses suffered by the estate or survivors of the deceased (technically called a wrongful death claim). To understand these concepts, it is helpful to understand some history behind the law of wrongful death and survivorship.

Wrongful Death Law in Early English Legal History

Ironically, the Anglo-American civil law of wrongful death actions has now come full circle. What in old medieval England was accepted as a right, and what 19th-century English and American courts ruled to have no legal basis, is now in 21st-century American legislatures and courts again recognized as a private right to recover damages for a fatal wrong committed on another.

In Anglo-Saxon England, a homicide in any form was regarded as a "tort," a civil offense, or a private wrong. To prevent private retaliation or family feuds and to encourage some form of peaceful resolutions, damages for killing a person were payable to the deceased's relatives. In medieval Anglo-Saxon law, this punitive reparation, termed *bot, wer,* or *wergild* ("man's-price" or "man-payment"), was paid by the wrongdoer to the kinsman of the decedent. At first, the amount of payment was set by a kind of arbitration; later, a scale of payments was established based on the social rank of the decedent. As society's attitude toward homicide changed, so did its legal remedies. Homicide was no longer viewed as a wrong to the decedent's survivors but rather as an offense against the state. By the 13th century Year Books (medieval English law reports), the evolution for redressing wrongful death was complete—every homicide became a criminal offence. Accidental and involuntary homicide were not classed as felonies, nor was the killer subject to capital punishment. As in most felonies, the defendant's property was forfeited to the state. Such killings were called "homicides *per infortunium*" and were not crimes but "misfortunes."

No private action by survivors was allowed at this early stage of English jurisprudence, partly because homicide per infortunium involved the forfeiture of the prisoner's goods. The "merger doctrine," which says a tort is merged into a crime, probably derives from this situation. Therefore, if the defendant's goods belonged to the Crown, it was useless to attempt to obtain them.

The acknowledged origin of the court-made or common law rule denying a right of recovery for the death of any person killed by the wrongful act of another derives from the 1808 dictum (i.e., expressions in a court's written opinion that go beyond the facts and do not directly apply to the facts or issues in that case and are therefore the personal views of the author and not binding on subsequent courts) of Lord Ellenborough in *Baker v. Bolton* (1808). In that case, the plaintiff's wife was fatally injured in a stagecoach accident and died 1 month later. Plaintiff sued the stagecoach owner, claiming he had "been deprived of the comfort, fellowship, and assistance of his said wife, and had from thence hitherto suffered and undergone great grief, vexation, and anguish of mind."

At trial, Lord Ellenborough instructed the jury that only damages for plaintiff's loss of society and grief could be awarded, and limited to the one-month period between the accident and his wife's death. As stated, in his infamous dictum: "In a civil court, the death of a human being could not be complained of as an injury."

Unfortunately, the illogic and unfairness of the *Baker* case was accepted by the American courts. The case was a statement of law without foundation in precedent or reason. But, like any bad precedent, subsequent judges adopting the rule advanced rationalizations for the refusal to recognize any civil cause of action for wrongful death. For example, some courts argued it was inconsistent with public policy to permit the value of human life to be subject to judicial computation or that recognition of a wrongful death action would result in the opening of a "floodgate," "numberless actions" for damage of an "awful magnitude."

These Victorian arguments lose much force when it is realized that they were advanced after the 1846 passage of Lord Campbell's Act in England, which created a right of action for wrongful death. The rationalizations for the "rule" of *Baker v. Bolton* have received much criticism. Adverse comment on this common law rule denying the right to recover for wrongful death may be found in numerous decisions and from legal scholars. The most likely reason for adoption of "the English Rule" in America is simply that it had the blessing of age. The U.S. Supreme Court has many telling answers to the old make-weight arguments about the difficulty and repugnance in valuing human life.

In *Moragne v. States Marine Lines, Inc.* (1970), the U.S. Supreme Court unanimously made one of the most important death case holdings in American jurisprudence. *Moragne* allowed a widow to assert wrongful death claims based on unseaworthiness for her husband-longshoreman's death that occurred while he was working aboard the ship owner's vessel within Florida's navigable waters. The Florida courts had held that the Florida death statute did not allow recovery for unseaworthiness. But, the Supreme Court overruled these courts, refusing to follow the common-law rule that no civil action lies for an injury resulting in death.

Although *Moragne* is important for maritime law, it is more important in the evolution in jurisprudence for rejecting the validity of *Baker v. Bolton*. The Supreme Court clearly and unequivocally ruled that there was no basis for adopting the *Baker* doctrine in the United States, and that the doctrine had been discarded even in England. Having put to rest the misconception that no common law right to sue for wrongful death existed, the Supreme Court went on to write a new nonstatutory remedy for wrongful death in maritime law.

The First Wrongful Death Act: Lord Campbell's Act

As a result of the general rule announced in *Baker v. Bolton* that "in a civil court the death of a human being could not be complained of as an injury," it was actually cheaper for a defendant wrongdoer to kill a plaintiff than to injure him. Furthermore, a victim's family was left without recourse. This injustice was remedied by England with the Fatal Accidents Act of 1846, also called Lord Campbell's Act. Titled "an Act for compensating the Families of Persons killed by accidents," it provided that whenever the death of any person is caused by the wrongful act of another, in such a manner as would have entitled the party injured to have sued had death not ensued, an action may be maintained after death in the name of his or her executor or administrator for the benefit of certain relatives. These include the spouse, parent, and child. The jury is allowed to award such damages as it may think resulted to the respective persons for whose benefit the action is brought; these damages are divided among beneficiaries in such shares as the jury by its verdict may direct. Lord Campbell's Act created a new cause of action based on a defendant's wrongful act, limited recovery to certain beneficiaries, and measured damages with respect to the loss suffered by these beneficiaries.

Wrongful Death Law in America

Building on Lord Campbell's Act, the first wrongful death statute in the United States was enacted in New York in 1847. Presently, statutes in every state create a right to recover for wrongful death. Many statutes substantially embody Lord Campbell's Act and create a right of action for losses suffered by statutorily designated beneficiaries as a result of the death. Others may be broadly classified as statutes under which death damages are measured by the loss occasioned to the decedent's estate by the death.

An important historical note is that most of the states that follow the 1846 Lord Campbell's Act unfortunately followed its "economic" damages approach. That is, most statutes were passed before or during the Industrial Revolution, at a time of child labor; almost every child in an American family was expected to earn income for the parents. Therefore, a child's death had an economic impact on the family's productivity: The loss

would usually result in an economic hardship for parents who not only lost a loved one but a productive farmhand or shop or factory worker. But if no immediate family member was "economically dependent" on the deceased, some wrongful death statutes provided no recovery for any survivors.

The language in the death statutes of each American jurisdiction varies widely. Each has different constructions or interpretations by respective courts regarding the persons for whose benefits an action may be brought, and the measure, elements, and distribution of damages. Additionally, many states have laws covering special situations, and several statutory wrongful death actions have been created under federal law. Each state has some statutory system for wrongful death damages.

The Survival or Survivorship Claim

Conceptually, a survival statute is different from a wrongful death act. Each provides a remedy for a different loss. Wrongful death acts compensate either the survivors or deceased's estate for losses they sustain. Survival statutes, on the other hand, permit recovery by the decedent's personal representative, generally on behalf of the estate—subject to certain exceptions where recovery is on behalf of the spouse, children, parents, dependent next of kin, and so on—for damages that the decedent could have recovered had he or she lived. Although originating in and caused by the same wrongful act, the cause of action that "survives" by statute is for the wrong to the injured person; the wrongful death action, under the usual Lord Campbell's Act type of death statute, addresses the wrong to the beneficiaries.

The elements of damages recoverable under survival statutes are generally as follows: conscious pain and suffering; medical, funeral and burial expenses; and loss of earnings, usually from the time of injury to the time of death. In some cases, damages are allowed for the loss of prospective economic benefit to the estate measured by the prospective net lifetime earnings discounted to present value. In some jurisdictions, punitive damages, compensatory damages for mental anguish or any outrage to the feelings of the injured person, fear, anxiety, and emotional distress prior to any injury may also be recovered. The majority of jurisdictions allow damages for a decedent's conscious pain and suffering prior to death under survival statutes and the hybrid type of survival-wrongful death statutes.

Wrongful Death Acts That Address Losses to Survivors

Lord Campbell's Act is the best example of this system of wrongful death law recovery for the benefit of survivors. This type of legal cause of action is for the protection of the survivor's "interest in the nature of an expectancy," and for the "exclusive benefit of the named beneficiaries."

However, a serious, recurring problem arises with the wrongful death of a child who is not employed and making no present monetary contributions to anyone. When the earning capacity of children becomes a realized fact, the children usually have become independent and are supporting their own families. From a pure economic viewpoint, a child today is probably a net liability to parents. The human loss to any parent from the death of a child is inexplicably great, but when examined in the cold calculations of Lord Campbell's "pecuniary loss," it is not pecuniary. Nevertheless, most courts do permit an award of damages for the parents' loss of a child as a result of wrongful conduct, and some state statutes wisely make specific provision for recovery of damages for a child's death.

Some courts allow damages for the lost inheritance or the diminution of inheritance caused by death in an amount the beneficiary would probably have received from the decedent by will or intestacy. If proven, this is considered "a pecuniary loss." Some courts, under Lord Campbell's Act statutes, allow damages for the "economic value" of the loss of advice, counsel, help, instruction, and guidance that were reasonably expected by the beneficiaries from the decedent.

Wrongful Death Acts That Address Losses to the Estate

In some states, the loss to the estate of a deceased is still measured, even where there are no surviving dependents. That is, the deceased's lifetime earnings are recoverable for the estate, even though the deceased was not financially supporting any family members.

Under the theory of these statutes, expenses incurred by the deceased before death are not included in any damages because these statutes redress the injury caused by the death. These statutes, like those patterned after Lord Campbell's Act, usually allow no damages for the deceased's

premorbid anxiety, fear, pain, and suffering, nor for the survivors' grief, sorrow, and emotional distress.

Conclusion

Death and civil damages for death are subject to rules and laws peculiar to the individual statutes and interpreting case law of the specific jurisdiction. In a general sense, recent laws and decisions over the past 100 years seem to be moving in the direction of allowing recovery of intangible losses and the protection and legal recognition of the grief and bereavement of survivors.

Beginning in the 1980s, the American civil justice system and tort laws, including wrongful death laws, came under vigorous and vitriolic attack by so-called "tort reformers." Special interest rhetoric claimed the rising cost of liability insurance was putting doctors out of business, keeping Girl Scouts from selling cookies, and preventing drug companies from producing new and valuable products for the public good. Unfortunately for victims of neglect and recklessness, the public's perception and reality often differ.

Some "tort reform" measures eliminated or altered "joint and several liability." That is, at common law if two or more defendants were each liable for conduct that legally caused a plaintiff's injury or death, then the plaintiff had the option to collect the full assessed damages from any one or all defendants. Some states eliminated or altered the "collateral source rule." Any benefits paid for medical bills or other out-of-pocket losses to a plaintiff are deducted from awarded damages, unless such benefits are from insurance that has a right to subrogate; in some cases, the insurance premiums paid by a plaintiff can still be recovered as damages. Relevant to our discussion of civil remedies for death, it is important to recognize that some tort reform laws in some jurisdictions have the effect of limiting the amount of recovery for survivors and victims of wrongful death.

Except for those states with statutory limits on nonpecuniary losses, none of the 50 states has any limits on pecuniary loss caused by wrongful death. Just as the law has expanded the remedies for injuries to emotional interests, the vast majority of jurisdictions now allow recovery for lost companionship, society, or consortium suffered by survivors of a wrongful death.

Deciding on a course of legal action to take after the death of a loved one may seem unsympathetic and calculating; however, the perishable rights, future needs, and the well-being of the deceased's family and survivors are important and time-sensitive considerations. Naturally the grieving process takes time and help from loved ones and close friends. Civil laws that may help replace, punish, and retrieve the decedent's wrongful loss have short time limits. Statutes of limitation within which a lawsuit must be filed or tort claims notices filed with known or suspected wrongdoers usually begin with the date of death. Therefore, in a compassionate and expeditious manner, some regard must be given to civil laws and methods of compensating wrongful death.

Zombies, Revenants, Vampires, and Reanimated Corpses

The general names given to the undead are zombies, revenants, vampires, and reanimated corpses. The undead are either *corporeal undead* or *corporeal living dead*. The corporeal undead include those animated undead who are commonly called revenants and vampires who have transformed while being undead. Zombies are the corporeal living dead. According to outward appearances, the corporeal living dead appear dead and are close to death (their senses are numbed and body functions reduced), but they are actually alive and cognizant of their surroundings.

Overview

The plea by parents to their children to "hush or you'll wake the dead" continues the ancient and culturally pervasive entrenched fear that a human body could actually return to the land of the living. When a person dies, we wish it was not true and that we could see that person again; but a fear can also exist that if that individual did rise from the dead, he or she might be malevolent. Would a person see that individual as a spirit or ghost, or would that individual rise from the grave as a decayed corpse? The fear of the presence of a moving, tangible, dead person that could be touched and could physically touch you has created the undead monsters that cultures throughout the world not only fear but also place in modern popular culture.

People from various cultures visualize the walking dead differently. Appearances of the walking dead include that they can ooze and be bloody with maggots crawling, they can lumber and stumble around, or they can fly and travel at fast speeds. They are usually visualized as being soulless also.

Zombies

Zombies are seen as individuals who look as if they are dead, but they are in fact living. It is in the Haitian community and the Vodoun (voodoo) faith where zombies are prominent and legitimately feared. The word zombie has traveled from Africa to Haiti and most likely came from the Kongo word *nzambi,* which translates somewhat into "spirit of a dead person." The process of zombification involves essentially being poisoned by a blend of substances made into a powder that might include as ingredients ground-up human remains, botanical dissociatives, and a neurotoxin (tetrodotoxin) from either the porcupine fish (*Diodon hystrix* L. and *Diodon holacanthus* L.), the puffer fish (*Sphoeroides testudineus* L. and *Sphoeroides spengleri* Bloch), and/or the Marine toad (*Bufo marinus* L.). One poison concoction could include toxic fish that are sun dried, heated, and placed in a mortar with roasted tarantula, nonvenomous lizards, parts of the brown and white toad, and ground-up human bones. The *bokor,* who makes the poison, covers his body with oil and wraps hemp sacks around him. He plugs his nostrils and covers his head with a hat to prevent from being affected. As the poison starts

its work, a person feels the sensation of tiny bugs crawling under the skin. A small amount of the powder mixture eaten in food or delivered by the prick of a thorn or directly into a wound makes a victim unable to move or speak, but they are conscious of their surroundings. The nervous system's motor responses are paralyzed. The mouth will not open and the eyes do not react to stimulus. It is possible to die of this type of poisoning because the heart rate and body temperature drop and breathing is markedly slowed and can result in asphyxiation. If the victim recovers, they fully recall their time as a zombie.

Zombie powders are administered by a *houngan* (good priest and healer) or a *bokor* (evil sorcerer). Both individuals are able to do the zombification on a victim and both are able to create an antidote. The good priest is able to create a zombie as revenge for a malevolent zombification or for placing other evil curses on a good victim. Conversely, the malevolent sorcerer creates a zombie to hold power over someone and, by not administering an antidote, could make a victim weak and subsequently die. Antidotes are mixed locally and vary from one region of Haiti to another, some requiring 30 or more ingredients, including leaves of medicinal plants such as aloe (*Aloe vera* L.), guaiac (*Guaiacum officinale* L.), and *cadaver gaté* (cf. *Capparis* sp.), mixed with odds and ends such as rock salt, mothballs, ground match heads, and sulfur powder. Scientists indicate that the tetrodotoxins have no known antidote. Some individuals believe that salt may be a key ingredient in the return of a zombie to the living because tetrodotoxins block sodium ion channels in nerve cell membranes. The bokor believe the return to the living is due to magic.

Three kinds of zombies are thought to exist. A *zombi astral* (also known as *zombi efface*) is created by an individual who comes to possess a victim's soul and alters a portion of that victim's soul. Those zombies that do make it back to the land of the living are *zombi savanne*. A *zombi cadaver* (also known as *zombi jardin*) is a creation that will be doomed to servitude to some master or its creator. These are the type of zombies that are found in the movies of popular culture, such as *White Zombies* (1933), *I Walked With a Zombie* (1943), *Zombies of the Stratosphere* (1953), *Night of the Living Dead* (1968), *Dawn of the Dead* (1978), *Chopper Chicks in Zombietown* (1991), *Boy Eats Girl* (2005), and *I Am Legend* (2007).

Revenants

A revenant is a person who was not well liked in life, was murdered or dies, and then is malevolent to the living when he returns from the dead. The revenant either goes after those who murdered him or pesters the living as an animated corpse. In folklore, the revenant is prominent in Western Europe. The French give us the verb root word *revenir,* which means to come back. Many of the accounts of revenants come from the Middle Ages during the 11th to 13th centuries. William of Newburgh wrote about many cases of revenants in the 12th century. He recounted that upon his return, a revenant filled the air with a foul stench and in his travels spread a deadly plague among the living. An English abbot of Burton in the 12th century also recounted a tale of two revenants. Two peasants who had run away from their lord died and were buried. They rose from the dead the same day and lugged their coffins with them around their village. They spoke to the villagers, warning them to leave. The villagers were stricken with disease and died immediately. The only true way of getting rid of these revenants was to dig up their corpses, cut their heads off, and burn or remove their hearts. Vampires are exterminated in a similar manner, but some folklorists say that vampires were a creation of Eastern European folklore, while the revenant comes from Western European folklore. Many anthropologists and folklorists assert that revenant is a generic term for the undead.

Vampires

Vampires are historically evil. They are the malevolent undead whose bodies rise to feed on living humans and, when necessary, animals. Vampires need to kill and feed in order to resurrect and transform into the living dead, and that necessary feeding will quench the thirst or stave off the hunger for only so long. Then the vampire must kill and feed again.

The vampire is a cross-cultural phenomenon and is not just the Dracula creation spawned by the mind of Bram Stoker, who was influenced by the horrific deeds of Vlad the Impaler. People

from many different cultures believe in a type of vampire creature and have created close to 100 different names for it. For example, vampires are known as: *loogaroo* (Haiti), *yara-ma-yha-who* (Australian Aborigines), *bluatsauger* (Germany), *vipir* (Bulgaria), *vrykolakas* (Greece), *rakshasas* (India), *langsuyar* (Malaysia), *kappa* (Japan), and the *chiang-shih* (China).

Peter Plogojowitz

There are many stories about how someone becomes a vampire. One of the most famous involves Peter Plogojowitz, who lived during the 1700s. The man called Peter died and was soon buried. The village that he lived in went through some hard times and was stricken with misfortune about 10 weeks after Peter died. An epidemic of some type made nine people sick and each died within a day. All nine were dead within 1 week. Several of those who were about to die blamed Peter Plogojowitz, indicating that he had come back from the dead and had physically lain on them and choked them while they were sleeping. The villagers were scared and felt they would only truly know if Peter was causing the deaths if they exhumed his remains and saw certain signs that would indicate that he was a vampire. They believed he would be a vampire if his body looked as if he were alive, if his hair and nails were longer, and if his body looked fatter, the latter evidence for his having feasted on the living. The villagers exhumed the body. Peter's hair and nails had grown. His old skin had been replaced by youthful skin. There was blood present in his mouth indicating his last meal on the living. The villagers took a sharpened wooden stake and drove it into his heart. Blood gushed from the heart, nose, and ears. The villagers had prevented the vampire from future malevolent activities.

Decomposition and the Vampire

The fear generated by the vampire comes from a pervasive dread of death and what happens to the body after one dies. The physical appearance of the vampire in lore and legend derives from unfamiliarity with the processes of decomposition. Currently, we know that a body goes through five stages of decomposition. It is the first three stages before skeletonization that figure into the vampire legend. During the first stage, human remains give off little odor and no color or skin changes can be seen. But unseen bacteria are working to decompose the tissue. The second stage is characterized by skin color changes on the corpse. Pink, white to gray, green, and brown colors can be seen on the fingers, ears, and nose. Eventually, parts of the arms and legs can turn black. The body starts to smell, and body parts bloat due to gas buildup inside the corpse, whereas other parts look as they did in life. Skin sags and hair can fall off. The third stage of decomposition is where the body emits the foulest odors, voices the creepiest sounds, and can look as if it were moving. Gases escape from the corpse, the abdominal wall caves in, and maggot masses at orifices move, drop, and crackle. The activity is furious and generates heat. Bone becomes evident, and adipocere, a breakdown of body tissues into a soapy material, develops. To the unknowing, hair and nails may appear to be growing, but they are really being shed due to decomposition. Skin sags and slips, making things appear to grow. Tissue retreats, and teeth in general and canine in specific become more prominent. Gas buildup enlarges the face, scrotum, and vulva areas, which before death may have appeared wasted away. These areas now look full of life. The sounds and the movement of the maggots make the corpse look as if it is moving in its repose. And, more importantly, fluids mixed with blood can stream from the mouth and nose, creating the appearance of an undead having recently fed on the living.

Tuberculosis and Vampires

In New England during the end of the 18th century and into the 19th century, the disease tuberculosis perpetuated the vampire myth. Individuals who died of tuberculosis often coughed up blood during their final days. Because the disease is highly contagious, family members or close friends of the deceased often came down with tuberculosis. The disease wastes away the body, draining an individual of energy, and they eventually started coughing up blood. The presence of blood around the mouth and the wasting away of a healthy individual fed the fear that the deceased individual was coming back and feasting on the living by draining them of their life force. In one town of West Stafford, five

out of six sisters were stricken with tuberculosis. It was firmly believed that the undead were coming back and feasting on the sisters until they died. To halt the demise of a doomed sister or relatives of the sisters, an exhumation of the five deceased sisters was performed at night and their heart and lungs were burned. It was felt that the heart and lungs kept some spark of life after death, and these needed to be destroyed. Once these organs were destroyed, the living could resume their good health.

The Vampire in Popular Culture

Lord Byron and John Polidori were two 19th-century writers who brought the vampire into popular culture through a case of literary theft. Lord Byron wrote the novel about a Greek vampire who is known in some literary circles as Augustus Darvell. John Polidori was Byron's doctor who took Byron's idea and wrote *The Vampyre,* which was published in 1819. Thus through this publication, the vampire began its rise into everyday life. Plays, operas, and musicals were written featuring vampires. Stories and novels continued to be written about vampires, such as *Varney the Vampire* (1847), *Carmilla* (1872), and of course *Dracula* (1897).

There is no monster in popular literature today that has spawned more novels than the vampire. A resurgence and steadily increasing proliferation of vampire literature began with works such as *Salem's Lot* (1976), *Interview With a Vampire* (1977), and *Hotel Transylvania* (1979). Because of these publications, vampires are everywhere in books and comics. They are housewives and crime fighters. They meet Sherlock Holmes, the Hardy Boys, and Nancy Drew. They are rabbits (*Bunnicula*), and they are ducks (*Count Duckula*). Vampires have remained a favorite monster at the box office. Many vampire movies have been made all over the world since the early two-minute film by George Méliès called *The Haunted Castle* (1896), *Nosferatu* (1922) directed by Murnau, and *Dracula* (1931) with Bela Lugosi.

Reanimated Corpses

It was Mary Shelley who brought the reanimated corpse into popular view with her novel *Frankenstein* (1818). Her story came at a time when people in England and America were becoming aware of the practice of robbing graves. Not only were corpses being mugged for valued possessions, but also body parts and whole bodies were being snatched. Body fat was being taken to make candles. Cadaver teeth, especially incisors and canines, which were easier to extract from the front of the mouth of a corpse, were valuable during the early 1800s, as they were used to make false teeth. Corpses were even stolen for ransom. Also during the 1800s corpses were stolen for medical purposes, such as providing a body for anatomical dissection. All the elements were present for Mary Shelley's monster, including the idea of how a snatched corpse could come back to life and how is it done.

Ancient Egyptian Mummy Reanimation

One of the most popular cultural monster characters is the mummy who is brought back from the dead. Many ancient Egyptian mummies have been uncovered in the sands of Egypt, indicating a population preoccupied with death. Their lives were centered on the preparations for death and the afterlife. The Egyptians loved life and wanted to carry this passion into the afterlife. A newly deceased individual would be mourned for 70 days. It was during this time that the process of embalming the corpse would take place. Corpses were dried using a natural salt called natron. Organs were removed and placed in jars to be used in the afterlife, and the body was softened and plumped up to look as lifelike as possible and then wrapped in linens. During the mourning period, an attempt was made to reanimate some of the organs and senses of the body through a ceremony called the "Opening of the Mouth." During the ritual, either the mummy itself or a statue of the individual would be touched by special tools in areas such as the mouth and eyes. After the symbolic touch of the eyes and mouth, those senses would revive; reanimation had begun. The corpse could now see, breathe, eat, drink, and more importantly, speak. It was necessary for the corpse to be able to speak words that would allow him to enter the afterlife. Family members would bring meals to the corpse and speak to the corpse during the mourning period.

Modern Reanimated Corpses

Some people want their corpse frozen after death so that in the future, when the pathological condition

that caused their demise can be reversed along with the process of death, their corpse can be reanimated. The idea of cryopreservation of humans is credited to Robert Ettinger, who founded the Cryonics Institute. The first person to be frozen for future reanimation was James Bedford, who died of lung cancer in 1967. Soon after death, his body was prepared by heparin infusions to prevent clotting of blood and a heart-lung machine kept nutrients and oxygen flowing to the brain while the body was packed in ice. Bedford's body was wrapped and placed in a cryogenic capsule that was filled with liquid nitrogen at a temperature of –320°F.

In some instances only the head is frozen because of the belief that in the future the rest of the body can be regrown. Although the corpses presently sustained through the cryonics process may not be reanimated in the future, scientists could benefit from research conducted on corpses with low to nonexistent decomposition.

GROWW-Grief Recovery Online
11877 Douglas Road, #102-PMB101, Alpharetta, GA 30005
Staff@GROWW.org
GROWW is a place where peer groups in an online chatroom environment teach that you have "permission to grieve" and where you learn that the emotions you can't understand are seen in a "mirror image" of someone describing exactly what you are going through. It becomes a place where you learn that by receiving the support and understanding that helped you get through the pain of losing a loved one, you can then help someone else who is beginning the grieving process.

The World Health Organization is an international body, under the auspices of the United Nations, whose primary function is to address global health problems by providing technical assistance to governments, implementing evidenced-based best practices for addressing disease and death risks, and providing surveillance of emerging mortality trends (in addition to other important services). The World Health Organization came into existence on April 7, 1948, a few years after the founding of the United Nations.
